EXPLANATION OF EXEMPTIONS

SUBSECTIONS OF TITLE 5, UNITED STATES CODE, SECTION 552

(b)(1) (A) specifically authorized under criteria established by an Executive order to be kept secret in the interest of national defense or foreign policy and (B) are in fact properly classified to such Executive order;

(b)(2) related solely to the internal personnel rules and practices of an agency;

(b)(3) specifically exempted from disclosure by statute (other than section 552b of this title), provided that such statute(A) requires that the matters be withheld from the public in such a manner as to leave no discretion on issue, or (B) establishes particular criteria for withholding or refers to particular types of matters to be withheld;

(b)(4) trade secrets and commercial or financial information obtained from a person and privileged or confidential;

(b)(5) inter-agency or intra-agency memorandums or letters which would not be available by law to a party other than an agency in litigation with the agency;

(b)(6) personnel and medical files and similar files the disclosure of which would constitute a clearly unwarranted invasion of personal privacy;

(b)(7) records or information compiled for law enforcement purposes, but only to the extent that the production of such law enforcement records or information (A) could be reasonably be expected to interfere with enforcement proceedings, (B) would deprive a person of a right to a fair trial or an impartial adjudication, (C) could be reasonably expected to constitute an unwarranted invasion of personal privacy, (D) could reasonably be expected to disclose the identity of confidential source, including a State, local, or foreign agency or authority or any private institution which furnished information on a confidential basis, and, in the case of record or information compiled by a criminal law enforcement authority in the course of a criminal investigation, or by an agency conducting a lawful national security intelligence investigation, information furnished by a confidential source, (E) would disclose techniques and procedures for law enforcement investigations or prosecutions, or would disclose guidelines for law enforcement investigations or prosecutions if such disclosure could reasonably be expected to risk circumvention of the law, or (F) could reasonably be expected to endanger the life or physical safety of any individual;

(b)(8) contained in or related to examination, operating, or condition reports prepared by, on behalf of, or for the use of an agency responsible for the regulation or supervision of financial institutions; or

(b)(9) geological and geophysical information and data, including maps, concerning wells.

SUBSECTIONS OF TITLE 5, UNITED STATES CODE, SECTION 552a

(d)(5) information compiled in reasonable anticipation of a civil action proceeding;

(j)(2) material reporting investigative efforts pertaining to the enforcement of criminal law including efforts to prevent, control, or reduce crime or apprehend criminals;

(k)(1) information which is currently and properly classified pursuant to an Executive order in the interest of the national defense or foreign policy, for example, information involving intelligence sources or methods;

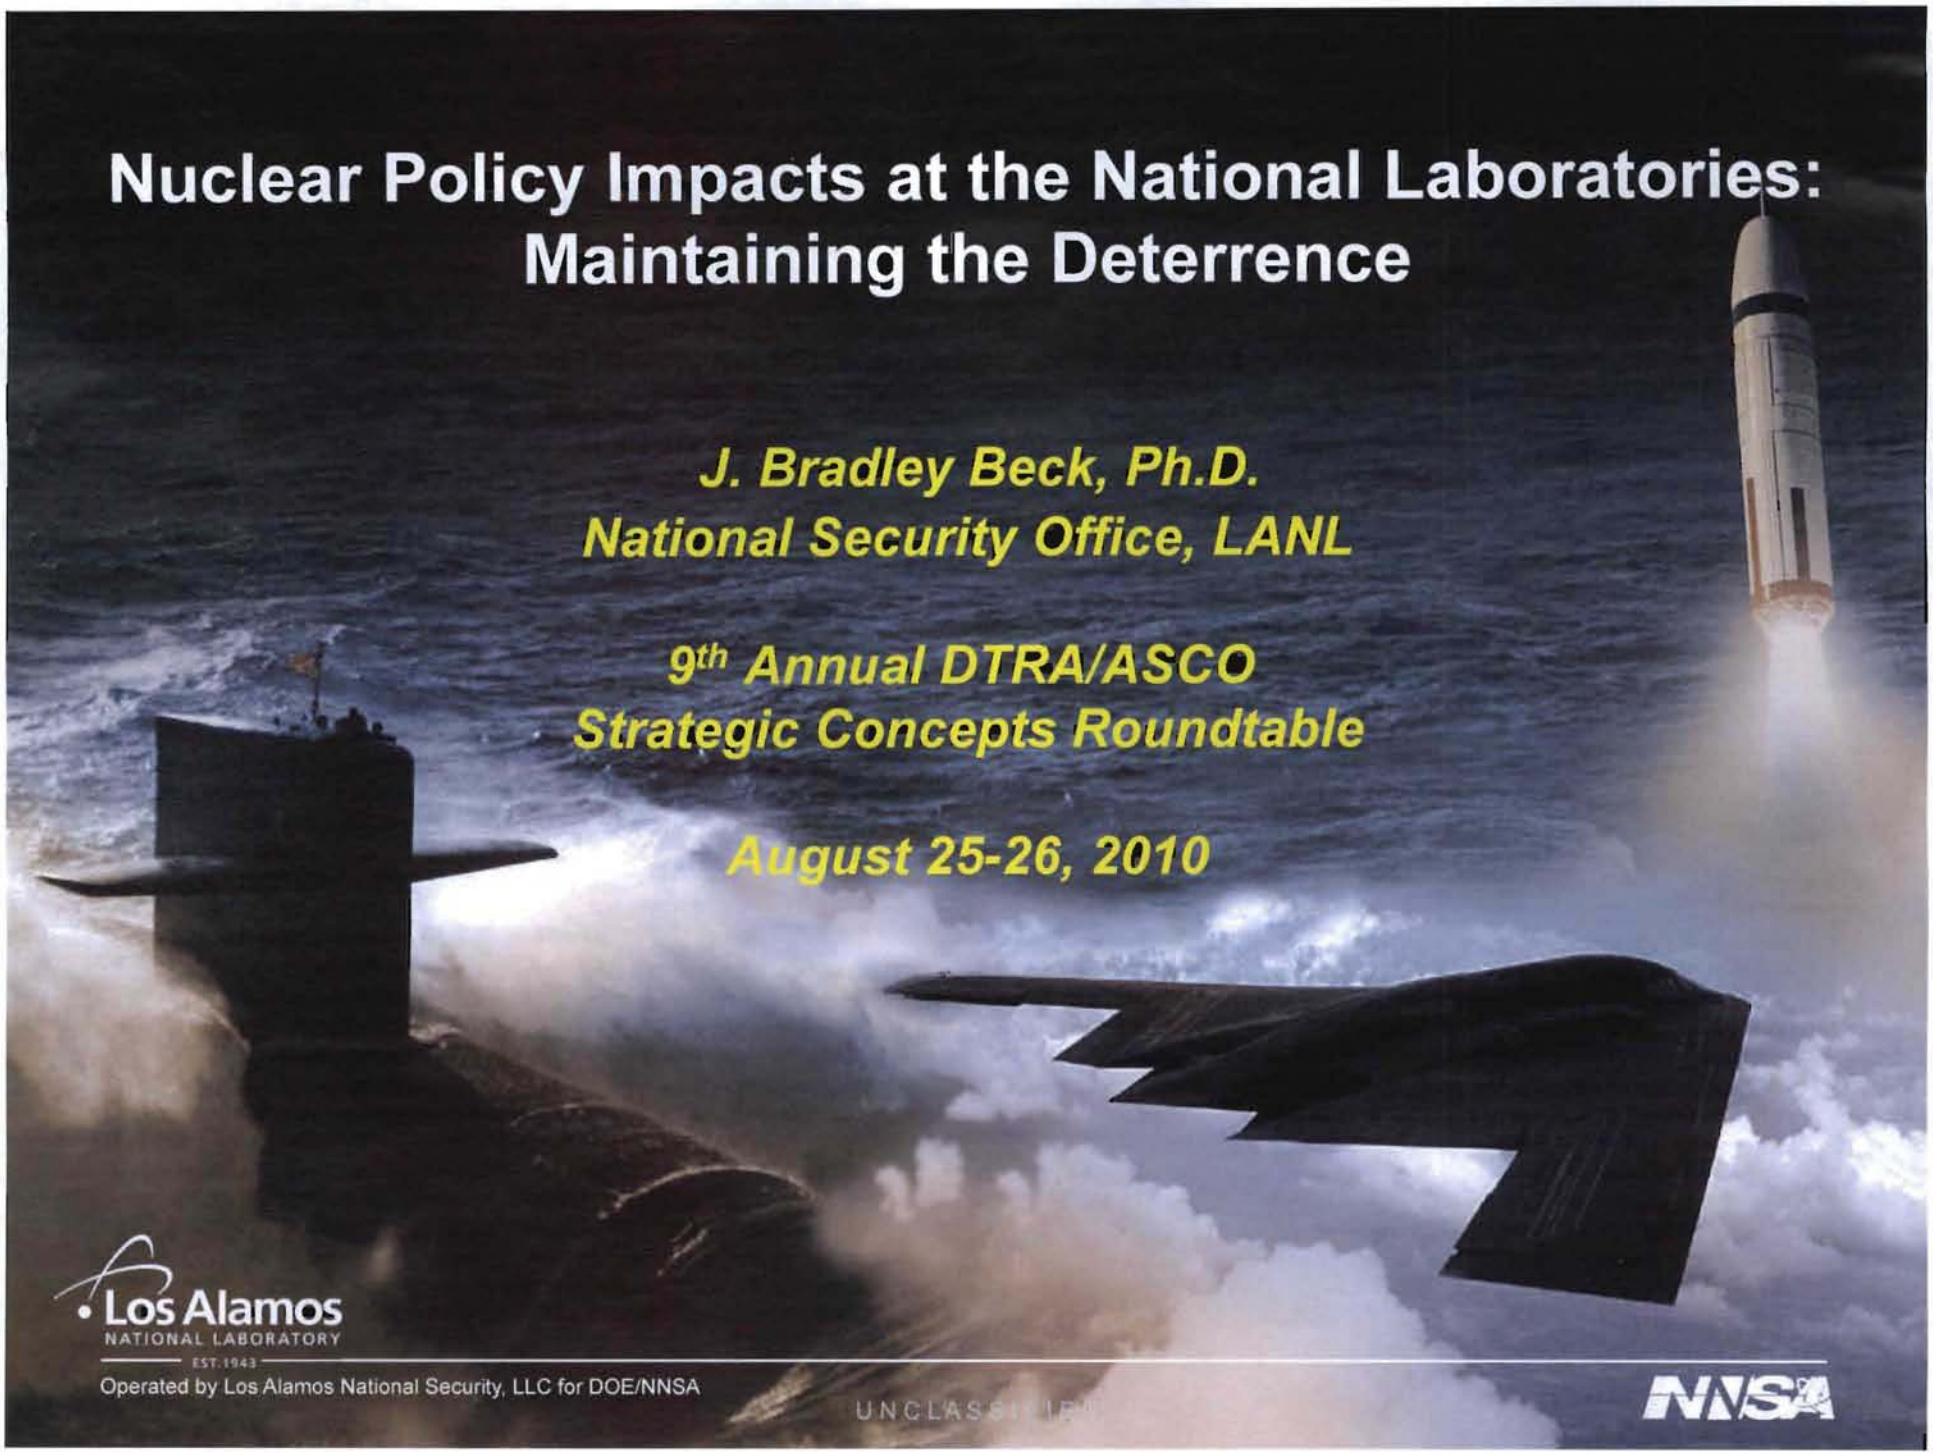
(k)(2) investigatory material compiled for law enforcement purposes, other than criminal, which did not result in loss of a right, benefit or privilege under Federal programs, or which would identify a source who furnished information pursuant to a promise that his/her identity would be held in confidence;

(k)(3) material maintained in connection with providing protective services to the President of the United States or any other individual pursuant to the authority of Title 18, United States Code, Section 3056;

(k)(4) required by statute to be maintained and used solely as statistical records;

(k)(5) investigatory material compiled solely for the purpose of determining suitability, eligibility, or qualifications for Federal civilian employment or for access to classified information, the disclosure of which would reveal the identity of the person who furnished information pursuant to a promise that his/her identity would be held in confidence;

(k)(6) testing or examination material used to determine individual qualifications for appointment or promotion in Federal Government service the release of which would compromise the testing or examination process;



(k)(7) material used to determine potential for promotion in the armed services, the disclosure of which would reveal the identity of the person who furnished the material pursuant to a promise that his/her identity would be held in confidence.

Nuclear Policy Impacts at the National Laboratories: Maintaining the Deterrence

The President and the Administration have a vision for the nuclear security for the United States (U)

...as long as [nuclear] weapons exist, the United States will maintain a safe, secure, and effective arsenal to deter any adversary, and guarantee that defense to our allies..."

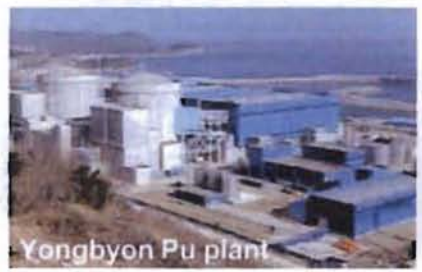
President Obama, Prague, April 2009

"[New START] ... maintains the flexibility ... we need to protect ... our national security and to guarantee our unwavering commitment to the security of our allies"

President Obama, Announcement of New START treaty, March 2009

"The NPR calls for ... much-needed investments to rebuild America's aging nuclear infrastructure ... I ... thank ... the Departments of Defense and Energy, including the national labs, [for] sustaining our nuclear arsenal."

Secretary Gates, Preface to NPR Report, April 2010



Possible Deterrence Failures

- Deterrence failure:
  - *When we do **not** deter an attack*
  - *WMD attack*
  - *Conventional weapons attack*
  - *When our friends and allies lose confidence in extended deterrence*
- Challenge: make sure this does not occur
  - *Use of technology is important (detection, forensics, …)*
  - *US maintains viable deterrent capability*

The Future Of Non-Strategic Nuclear Forces

Are These Capabilities Still Needed? (U)

by

Joseph S. Howard II
Edward I. Whitted

ABSTRACT (U)

The epochal political events of 1989–1990 are greatly influencing US non-strategic nuclear forces (NSNF). NATO NSNF strategy is undergoing revision. The London Communique of July 6, 1990 is the harbinger of an intense debate upon future NATO nuclear roles and missions. The President's cancellation of the Follow-on-to-Lance missile (FOTL) and the offer of withdrawal of forward-deployed nuclear cannon projectiles to NATO indicate downward trends in future NSNF stockpiles.

This report, in the form of an executive summary and an annotated briefing, presents the results of a yearlong policy and systems analysis investigation. The authors examine plausible rationale, first principles, that govern the justification for future NSNF. They then assess the capabilities of reduced stockpiles during 1995–2000 wherein regional powers may possess nuclear arms. By configuring three nuclear scenarios in which US vital interests are at stake, the authors analyze the number of NSNF weapons to investigate "how much NSNF is enough?" They also examine implications to the US Army should downward trends in short-range nuclear forces continue.

EXECUTIVE SUMMARY

Background

The world has witnessed such revolutionary changes over the past 18 months that clearly a new era has started. In this context, the authors undertook a study in late 1989 with partial Army support that would assess future European short-range nuclear force (SNF) structures and target sets. The rapidity of the political changes in Europe and the Soviet Union at the early stages of the effort motivated broadening the study to include strike non-strategic nuclear forces (NSNF) in a worldwide context. Also, the nature of the evolving era indicated that a traditional target-based analysis would be sadly deficient without underlying policy and economic assessments. These assessments have led us to conclude that, even more than before, future stockpiles will not be determined strictly on the basis of threat target defeat. Stockpiles will be configured from a complex interaction of domestic and international politics, defense budgets, arms control treaties, and differing threat perceptions.

The events in Europe are also affecting US NSNF strategies for other theaters. The outcome of future Nuclear Weapons Requirements Studies (NWRS) from the nuclear CINCs may profoundly affect NSNF roles and missions of the services. Trends in late 1990 were moving toward a denuclearization of the Army in the sense that organic nuclear systems might be retired.

Therefore, this paper examines the 1995-2000 rationale, roles, and capabilities of US NSNF in light of the revolutionary changes in Europe, plausible future nuclear threats worldwide, and downward trends in NSNF due to economic and political pressures.

Policy Findings: Strong Reasons for NSNF

The strategy and policy reassessment of US NSNF identified strong rationale for a continued role:

- As a visible instrument of superpower status in an uncertain and unpredictable world

- As a deterrent to future non-superpower nuclear-capable adversaries in a proliferated world

- As a deterrent to regional Soviet or Russian aggression as long as resurgence or reconstitution remains feasible

- To provide stability and insurance in a post-CFE Europe through a small air-delivered, forward-deployed force

Because of European politics, US NSNF structure decisions must be broader than peacetime NATO strategies, policies, and constraints.

The old *raison d'etre* for US NSNF: the Soviet Threat

1. **Democracies and economies of Western Europe**
2. **The overriding threat: the Soviet Union**
3. **NATO was unable to provide sufficient conventional forces**
4. **Deployment of nuclear weapons to Europe created an extended deterrence umbrella for conventional force deficiencies**

Other US CINCs were also allocated NSNF for deterrence of the worldwide Soviet Threat

Initially behind the deployment of US forward-based nuclear forces has been the threat of Soviet landpower, and subsequently the Soviets' own theater nuclear capabilities. The victory of the allies in the Second World War led to several unforeseen events: one was the raising of the Iron Curtain in the late 1940s through the subjection of Eastern European countries by the Soviet Union. The US, after fighting a war against totalitarianism, turned to a grand strategy of containment of Soviet imperialism. A free and prosperous Western Europe continued to be of utmost interest to the US; and therefore, the NATO alliance was formed to draw the line against further Soviet expansion. Unfortunately, the Soviet Union and its Warsaw Treaty Organization (WTO) alliance deployed forces far beyond those required for its own defense. Unable and unwilling to match the conventional force goals of the 1952 Lisbon Conference, the US deployed its first theater nuclear weapons for NATO in 1953.

Over the past 45 years, NATO nuclear doctrine has evolved from "massive retaliation" in MC 14/2, to "flexible response" in MC 14/3, then to the development of provisional political guidance (PPG) for initial and follow-on nuclear use, next to the Montebello modernization decisions, and now to the proposed "weapons of last resort" from last summer's London communique. But behind all of these declaratory doctrines and revisions, excepting the last, has been the massive Soviet threat.

The US strategy of extended deterrence, operative with the forward-deployment of US weapons and nuclear guarantees to the allies, has created a tension between the Europeans and the US. The presence of US weapons in Europe has been emphasized by the Europeans as a coupling to the US Central Strategic Forces. Hence, the specter of Armageddon must always reside in the calculus of the Soviet Union. Conversely to the US, the presence of theater nuclear weapons (now NSNF) gave an aura of credible response options before the ultimate response.

But Future Regional Threats dictate three NSNF Deterrent Rationales broader than European stability forces

War prevention and war termination where US vital interests are involved:

2. A visible symbol of national power in an uncertain & unpredictable multipolar world

3. A deterrent to future non-superpower nuclear-capable adversaries in a proliferated world

4. A deterrent to regional Soviet or Russian aggression as long as resurgence or reconstitution remains feasible.

NSNF Roles

- **An incalculable risk to the threat(s)**
- **Appropriate & credible non-strategic nuclear options including capabilities for in-kind nuclear response**
- **Direct defense of endangered US forces**

The first major rationale for NSNF derives from its contribution as a political instrument and an insurance policy for the superpower US Although not often on center stage in a number of regional disputes or conflicts, NSNF availability in the wings has certainly played an important role in diplomatic interchanges and crises.

A future nuclear-proliferated world would present enormous challenges to US defense interests. Over ten nations possess the capabilities to obtain nuclear armaments in the next decade. Several of these nations maintain profoundly hostile relations to the US As regional powers in their own right with significant conventional armaments, their addition of nuclear capability would raise grave risks to deployed US forces.

While the aggressive intentions of the Soviet Union towards Europe may have disappeared, their conventional and nuclear capabilities remain huge. While the short-warning scenarios are no longer credible, a future resurgent and mobilized Soviet Union remains feasible. While intentions can move towards amicability, they can subsequently be reversed upon change in leadership. The Soviet Union or the greater Russian Republic, should some republics become autonomous, may have future cause to counter US vital interests in critical regions such as Southwest Asia, despite present trusts.

Therefore, we are incredulous of US forces without NSNF to prevent war or to terminate war against hostile nuclear-armed states. The rationale for NSNF must rest upon its capabilities to deter a plausible resurgent Soviet Union, or any of several regional powers with potential nuclear capabilities. As NSNF kept the long peace in Europe because it engendered cautious behavior, so should NSNF be kept as an incalculable risk towards any nuclear state contemplating aggression.

The rationale for NSNF also involves the element of credibility: the NCA should have options other than central strategic forces for an appropriate response.

Current and programmed force systems provide a span of yields and ranges

DOE b(3)

- TLAM N with W80-0 [redacted]
- AF DCA with B61 Mods (3,4,5,9,10) or new TASM [redacted]
- Navy DCA with B61 Mods (5, 6, 8) and B90 NDSB [redacted]
- AF F-15E/F-111 with W91 SRAM T [redacted]
- Army Ground Systems - 8-in W79-0 and W79-1 [redacted]

Ranges & radiuses DoD b(1) deletions EO 1.5 (a), (c) & (e),

1990 planning documents of current and projected forces show a force with a wide span of yields and ranges. However, more realistic future projections cloud their availability.

DOE b(3) [redacted]

DOD b(1) EO 1.5(a) Another example would be early retirement of the W79. The W79-1 enhanced radiation warhead is very effective against troop formations. Many DCAs delivering gravity bombs would be needed to substitute, probably inadequately, for this capability loss.

A third example would be the cancellation of the SRAM T. Our subsequent analyses reveal that the additional demands on TLAM-N and penetrating DCAs would be unrealistically high. An option, should this come about, might be a common system which can be delivered by

Future NSNF options can be more limited in scope

1. Initial Use Options:
   - Credibly deter or respond to limited threat nuclear use
   - Defeat the most important war-supporting and projection force assets

2. Follow-on to Initial Use Options
   - Credibly deter or respond to threat nuclear use
   - Prevent overrun of committed US forces

3. Selective Employment Options
   - Credibly deter or respond to wider threat nuclear use
   - Defeat high-priority fixed targets, defeat maneuver divisions

[redacted] DoD b(1) EO 1.5(a),(c),(e),(g)

Unquestionably the number of potential NSNF targets has fallen dramatically.

[redacted] DoD b(1) EO 1.5(a) (e) (c) (g)

Notwithstanding, we think that CONUS-based US NSNF must be configured to meet operational requirements against potential threats: specifically a reconstituted Russian threat and two third-world nuclear threats at the same time.

[redacted] DoD b(1) EO 1.5(a) (e),(c),(g)

Under the three categories of options would be the mission to credibly deter aggression or respond to threat nuclear use. The traditional rationale of deterrence or restoration of deterrence would hold: war prevention and if need be, war termination.

Capabilities analysis assumptions

- Probability of Arrival = 1
- Probability of Defeat/Damage (PD) ≥ 0.90 required for fixed targets; 50% defeat of mobile target essential combat elements
- Moderate fixed target damage VNTK; 30% mobile unit coverage at 3000 cGy
- Fixed target density is uniformly distributed
- All targets treated equally & independently with only one weapon per target; I. e., PD = PSSK ≥ 0.90
- Maximum combat radius (HI-Low-Low-HI flight profile) and delivery accuracies

DoD and DoE b(1) EO 1.5(a)(c)(e)(g)

[redacted]

In general, we used a typical methodology and standard assumptions to arrive at stockpile requirements against the target sets.

The methodology assumed 100% reliably arriving weapon systems, one weapon per target, target elements uniformly distributed, and a 90% probability of single shot kill (PSSK). The target defeat criteria consisted of moderate VNTK damage on fixed targets and 50% defeat of a division's essential combat elements (ECEs). An ECE was considered defeated when 30% of its elements were covered by at least 3000 cGy (immediate transient incapacitation) by the effects of the W79-1 or a B61 bomb.

DoD and DoE b(3) FRD

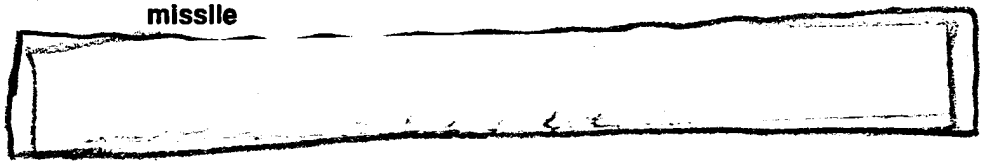
[redacted]

V. SUMMARY

Force Rationale
- Past rationale
- Start of a new epoch
- Determinants of a future US NSNF strategy

Force Assessment
- Roles and attributes
- Systems
- Numbers

Force Structure
- Army SNF
- SRAM T



Summary
- Findings
- Recommendations

The final section of this paper concludes with a summary of the previous findings; and based upon these findings, offers recommendations.

Recommendations

1. **Army should keep an organic capability**
   - **Maintain the W79 and 8-inch delivery as an interim system**
   - **At the appropriate time (suggest two years) initiate a study to**
     - Formally assess future Strategic Army battlefield nuclear missions
     - Examine organic Army force structure alternatives
     - Define technical options for future nuclear systems
2. **Air Force should develop a theater air-delivered stand-off missile**

DoD b(3) FRD

We make the above three recommendations based upon the essential findings of this study.

ACKNOWLEDGEMENTS

Many defense analysts graciously gave of their time in listening and commenting on earlier versions of this work. The nature of the policy analysis required us to use a non-attribution approach; therefore we will not generally recognize individuals who provided substantial information. However, special thanks are given for the support of Bob LaRocque, Ron McGee, Major Jeff Geoque, and Peggy Fratzl at TRAC-Leavenworth who provided invaluable programmatic and technical assistance to make this project possible.

The authors also give special thanks to Ron Pistone, Darrel Morgeson, Tom Dowler, Frank Smith, Boyd Wilson, Linda Trocki, and Pat Garrity at Los Alamos for their assistance as the project evolved.

History of Gun-Type Artillery-Fired Atomic Projectiles

Mk 9 Shell

The possibility of developing an artillery-delivered gun-type atomic device was discussed in late 1949 by Army Ordnance. This shell would be a defensive or offensive weapon against infantry masses concentrated in front of the sector through which a breakthrough was planned. It was hoped that a nuclear artillery shell, fuzed for air burst, could destroy the ability of these troops to stage an attack, or to defend the sector.

Possible delivery methods considered for such a weapon included railway rifles, guided missiles, aircraft, or artillery field pieces. Railway rifles, besides being almost obsolete, were ruled out due to heavy weight and relative immobility. Guided missiles capable of carrying atomic warheads were not as yet available. Bombing inaccuracy and difficulty in identifying battlefield targets made use of aircraft-delivered weapons unattractive.

It was felt, however, that artillery field pieces could be used, at least until suitable guided missiles became available. Army Ordnance had developed a mobile gun of 240-mm diameter (about 9-1/2 inches), weighing 90 tons, which was soon to be proof-fired, and a conference was held with Los Alamos Scientific Laboratory personnel November 10, 1949, at which use of this gun was advocated. The nuclear designers stated that a gun-type nuclear device would fit inside a 240-mm gun barrel, although concern was felt about the relatively inefficient usage of fissionable material in such an assembly.[1]

Another meeting was held on the same subject January 16-17, 1950. Increased Los Alamos interest in the project had developed, and Army Ordnance representatives discussed possible shell designs. One proposal was to develop a 240-mm-diameter shell, to fit the mobile gun, and another was to install a 280-mm barrel on the 240-mm mount, thus allowing the shell diameter to increase to about 11 inches.[2]

PREFACE

This report is one in a CNSS series that surveys the development of nuclear weapons over the past forty-five years. The unifying themes throughout the series are the technical advances and failures associated with new weapon systems, and the creation of the stockpile.

Authors, titles, and report numbers are listed below.

DoE b(3)

Rainier was detonated on September 19, 1957, in a tunnel in Area 12. Rainier also gave its name to the mesa into which the tunnels were dug (Rainier Mesa) and to the volcanic rocks that cap that mesa (Rainier Mesa Tuff).

DoE b(3)

58A

As more and more weapons entered stockpile and came into the hands of people less knowledgeable about nuclear design, questions about the safety of nuclear weapons assumed more importance. One of the first questions to receive serious attention was one-point safety. The requirement was that no more than four pounds of nuclear yield should be produced as a result of the detonation at *any* one point in the HE, perhaps because four pounds is small compared with the amount of HE in the various devices.

The design physicist was repeatedly scolded for presenting unpromising results. He was urged to make the system work. As a result, he took the most optimistic view of each of the several areas of uncertainty in the design—too optimistic, as it turned out. It was only the nuclear test that revealed the overly optimistic approach. In the absence of nuclear testing, the design errors might never have been uncovered.

DoE b(3)

If there were no tests to keep the system honest, nuclear designers could be pressured into certifying designs that would not work.

As a consequence of these concerns, a series of one-point tests was conducted at the NTS called Operation 58A, which included two safety tests, Venus and Uranus, of Livermore devices. These were carried out between Operation Plumbbob and Operation Hardtack.

DoE b(3)

DoE b(3)

There were other Livermore tests in Operation Plumbbob to which the Livermore Small-Weapons Group did not contribute.

Quince and Fig were fired on Runit (Yvonne) Island in Eniwetok Atoll as close to the ground as pos-

sible—the standoff of a few inches being required by the device designers to ensure that the presence of the ground did not perturb the implosion. This near-ground test was required to accommodate a fallout experiment conducted by Sandia.

DoE b(3)

DoE b(3)

DoE b(3)

There being no other NTS soil at hand, the Fig device was emplaced in the same location—radiation field or no. The Hamilton test was fired at the top of a 50-ft wood tower in Frenchman Flat, and Humboldt was fired atop a hastily constructed 25-ft wood tower in Area 3 of the NTS.

DoE b(3)

Laboratory interest in small, clean, and relatively clean warheads led to the testing of several unique systems.

XR SYSTEMS FOR OPERATION REDWING

INTRODUCTION

At the request of Los Alamos Scientific Laboratory and University of California Radiation Laboratory, Livermore Site, Sandia Corporation has prepared external initiator equipment for use in Operation REDWING. The external initiator equipment (XR) in general consists of a pulsed neutron source (S-Unit) similar to those used in Operation TEAPOT, designed and constructed by the General Electric X-Ray Department, a time delay circuit designed at Sandia Corporation and a power supply (MC 251 inverter). The purpose of this report is to describe the XR apparatus, systems and applications for Operation REDWING.

Requirements

The following is a summary of the shots for which XR is planned:

Shot Name	Ready Date	Responsible Laboratory	Device Being Initiated
LaCrosse	May 1	LASL	
Inca	June 8	UCRL	
Yuma	June 1	UCRL	
Kickapoo	June 18	UCRL	
Erie	May 23	LASL	
Seminole	May 28	LASL	
Flathead	June 2	LASL	
Blackfoot	June 7	LASL	
Mohawk	July 1	UCRL	
Huron	June 12	LASL	
Apache	July 1	UCRL	
Dakota		LASL	
Pawnee		LASL	

DOE 6(3)

For purposes of XR requirements the shots are broken into three groups. These groups are listed below with associated neutron requirements:

Type Group	Shot Name	Neutron Output per S-Unit	No. of S-Units Required
I			2
I			2
I			2
II			2
II			2
II			2
II			2
III			4
III			4
III			4
III			4
III			4
III			4

DOE 6(3)

Four S-Units may be required

SECRET
UNCLASSIFIED

Probability that the required number of neutrons will be furnished should be at least 95% and confidence level of this probability should be at least 95%.

DOE 6(3)

The exact desired time should be known three days prior to the ready date. This information should be directed to either B. J. Carr or N. J. Elliott, one of whom will be located on Paree Island, Building 415 after April 15, 1956.

Separation of the S-Unit from the HE systems has been left to the responsible laboratory in each case.

XR SYSTEM COMPONENTS

Each of the three XR systems to be used consists of several building blocks. These are (1) the neutron source (S-Unit), (2) the unit "B" junction box, and (3) the XR timer control box with time delay Unit "A". These parts are described in the next three sections.

The S-Unit

The pulsed neutron source unit S to be used in Operation REDWING is the S-5D unit which was developed by the General Electric X-Ray Department for Sandia Corporation. This unit has been described previously in the preliminary TEAPOT reports. It consists of a small pulsed linear accelerator which produces 14 MEV neutrons from an TD reaction.

DOE 6(3)

The entire unit is welded shut and is pressurized with SF_6. An outline drawing is shown in Figure 1. The size of

Ground Shock from Earth Penetrator Weapons

Paul Yarrington
Computational Physics & Mechanics Division II
Sandia National Laboratories
Albuquerque, New Mexico

ABSTRACT

This report presents results of calculations to predict ground shock effects from earth penetrating weapons. The study models 500 kiloton explosions at two depths below the ground surface in homogeneous, saturated, soft rock geology. Comparisons of weapon lethal range are made using various free-field damage criteria for near-surface and deeply-buried targets. Comparisons are also made with calculational results for ground shock from above-surface and shallowly-buried selected bursts.

2. Calculational Approach

The calculations reported here were performed with the two-dimensional, Eulerian wavecode, CSQII (version 6/82) [3], assuming cylindrical symmetry about the penetrator axis. The penetrator was modeled as a solid cylinder of iron, 30 cm in diameter and 180 cm long. The center of the penetrator was assumed to be at the nominal depth of burst for each problem. Energy release for the the EPW burst was simulated by uniformly depositing 500 kt (2.1×10^{22} ergs) of energy in the iron cylinder representing the penetrator, with the energy being deposited at a constant rate over a time interval of 20 nanoseconds.

The effects of the penetration event on the target material above the weapon were assumed to be of negligible importance to the energy coupling and ground shock associated with the EPW bursts. Thus, the target medium surrounding the weapon in all directions was modeled as uniform and undisturbed. Air above the ground surface was explicitly modeled in the calculations.

The ANEOS [4] equation-of-state (EOS) package associated with CSQ was used to model the materials in the calculations. A library EOS (ANEOS Library Material No. -5) was used for the iron penetrator, although, given the extremely high temperatures reached by the penetrator materials, the ground shock effects are essentially independent of the material chosen to model the projectile. A tabular EOS (Table No. 1885) was used for the air. The ANEOS input for the tuff is given in Appendix 1, while principal material properties are listed in Table 1. Material properties for the tuff were chosen to be the same as those used in an earlier Sandia calculational study [5] of ground shock effects. Hugoniot and selected release curves generated with the tuff model are shown in Figures 1 and 2.

3. Calculational Results and Description of Phenomenology

Within a few microseconds after the burst, the expanding cavity of vaporized tuff and weapon debris becomes essentially spherical. This can be seen in Figure 3, which shows the 1 Mbar pressure contour for the 6 m DOB problem at 50 microseconds, shortly before the burst breaks through the surface of the ground. Note that the center of burst was at the origin of the coordinate system in both of the EPW calculations. When breakout occurs, energy is rapidly lost from the cavity, as hot, high pressure gases vent to the atmosphere. Figure 4 shows a sequence of early-time pressure contours, where the strong hydrodynamic motions that occur following breakout are evident. Velocity and temperature profiles on axis during this cavity breakout phase of the problem are shown in Figure 5. Histories of total energy in the tuff and in the air are cross-plotted to a problem time of 10 ms in Figure 6, where the rapid, early-time transfer of energy from tuff to air can be clearly seen.

For the deeper burst, these processes occur later in time, and less energy is transferred to the air than for the shallower burst. Figure 7 compares pressure contours for the two EPW bursts at problem times of 2 ms, 6 ms and 10 ms. Figure 8 shows the time history of total energy in the air during the first 30 ms for the two problems. As time progresses, the pressure in the cavity for both bursts drops well below that for a fully-contained explosion [6], as shown in Figure 9.

Figure 10 compares late-time pressure contours for both problems and shows a somewhat stronger ground shock for the deeper burst, as would be expected. This is evident from the wider contours that are seen for the deeper burst at any given stress level. Compare, for example, the 0.5 kb contours (level E) for the two cases.

With the contour levels chosen in Figure 10, the front of a pressure wave can be seen propagating in the air along the ground surface, suggesting that some "airblast" effects may be associated with the EPW bursts. The strength of this blast wave is

greatly reduced, however, from that produced by a surface burst and will decay to negligible levels at ranges where the ground shock is still well above its lethal level. Thus, ground shock is definitely the dominant weapon effect against hardened structures for the EPW bursts simulated here, with "airblast" making virtually no contribution to the overall lethal radius of the weapon.

8.1 Introduction

DOE b(3)

Thermonuclear Burning

As seen in the preceding chapters, thermonuclear (D-D and D-T) reactions are used for the initiation and the boosting of nuclear fission chains.

The problem to be considered in this chapter is the development of methods whereby large amounts of energy may be produced from thermonuclear reactions.

The continuous release of energy in a thermonuclear system involves the propagation of a chain reaction; but this resembles a thermal chain, such as occurs in flame propagation, rather than a fission chain. In the latter, particles, i.e., neutrons, produced in one step of the reaction are the means for causing further (fission) reaction to occur. In a thermonuclear system, as in a flame, the energy liberated in the reaction raises a volume element to a high temperature. This heats an adjacent volume element sufficiently to permit the reaction to occur rapidly. The resulting increase of temperature then heats a further volume element, and so on, until the reaction (or flame) has spread throughout the whole system. It is this similarity between thermonuclear reactions and flame propagation that gives rise to the use of the term "burning" in the former case (see Section 1.6), as in the latter.

It should be noted that whether burning, i.e., propagation of the reactions, will occur or not, depends on a competition between the rate at which heat is produced by the reactions and that at which it is lost, from a given volume element, in various ways. The former must, of course, predominate if burning is to occur, and the temperature attained must be high enough for the reactions to be rapid.

Material and Radiation Energies

At temperatures of the order of a few thousand degrees, the energy of a system is almost entirely material energy, i.e., essentially thermal kinetic energy with perhaps a small amount of potential energy. This material energy, E_m, is proportional, approximately, to the mass, M, of the system and to its absolute temperature, T; thus,

DOE b(3)

$$E_m = aMT \,, \qquad (8.1)$$

UNCLASSIFIED

where a may, for the present purpose, be regarded as constant for the given system.

UNCLASSIFIED

$$D^2 + D^2 \rightleftharpoons \begin{cases} He^3 + n^1 + 3.27 \text{ Mev} \\ T^3 + H^1 + 4.04 \text{ Mev} \end{cases}$$

$$D^2 + T^3 \longrightarrow He^4 + n^1 + 17.6 \text{ Mev}.$$

It is seen that there are two alternative D-D reactions; they take place roughly at the same rates, so that each may be regarded as occurring in half the D-D interactions.

D-D and D-T Cross Sections

The rate of a nuclear process is usually expressed in terms of the effective area per nucleus, i.e., the cross section. These cross sections can be determined experimentally by accelerating deuterons or tritons to known energies and determining the extent of interaction with other (stationary) nuclei. The results obtained for the second of the D-D reactions given above, represented by DD_p, and for the D-T reaction are shown in Fig. 8.2. The values for the other D-D reaction are very similar. The cross sections, $\sigma(E)$, are expressed in barns, i.e., in units of 10^{-24} cm^2, as a function of the deuteron energy in kev.

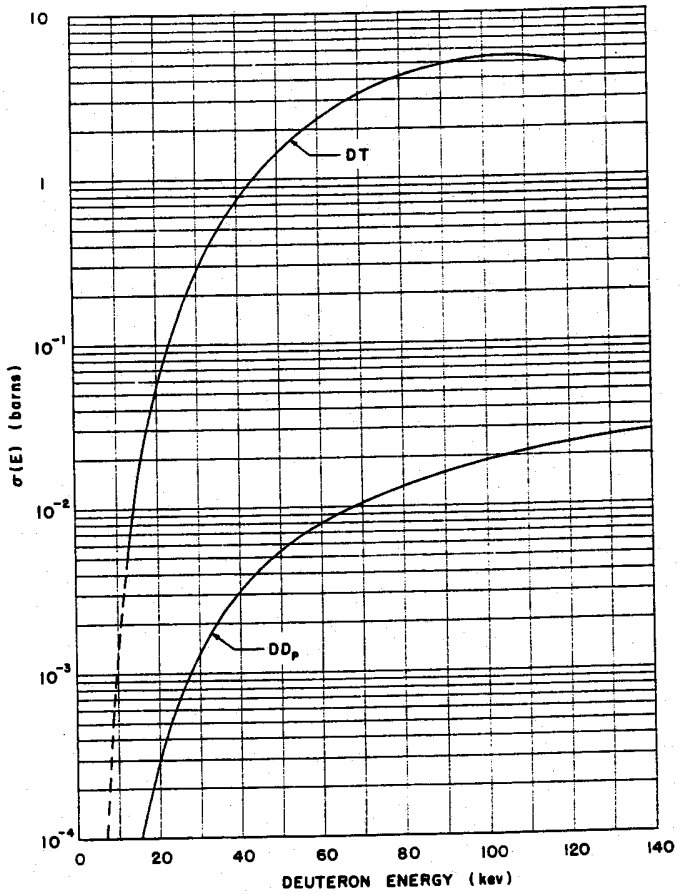

Fig. 8.2

The cross section, or reaction rate, is seen to increase with the energy, due to the increased probability of penetration of the potential barrier. It may be mentioned that the cross-section curve for the D-T reaction is not only somewhat higher than expected, but it also exhibits a maximum at energies around 100 kev (see Fig. 8.2). This is attributed to the phenomenon of resonance.

UNCLASSIFIED

Calculation of Reaction Rates

Consider a quantity of deuterium, and let the cross section, σ, represent the effective area of a nucleus of a given energy for the D-D reaction. If v is the velocity of the deuterium nucleus, then it will sweep out an effective volume σv in unit time, e.g., per sec. If there are N deuterons per cm^3, then the total effective volume swept out is σvN per cm^3 per sec. Since there are N deuterons present per cm^3, the number of effective D-D collisions, i.e., the rate of the D-D reaction, is equal to $\sigma vN^2/2$ per cm^3 per sec. The factor of one half is introduced here, for otherwise each D-D collision is counted twice. In the case of the D-T reaction, the corresponding rate would be σvN_dN_t per cm^3 per sec, where N_d and N_t are the numbers of deuterons and tritons, respectively, per unit volume.

It is seen from the foregoing argument that, apart from the density of the material, i.e., the number of nuclei per cm^3, the rate of a nuclear reaction is determined by the product σv. In a system at a given temperature, T, not all the nuclei will have the same energy and, hence, velocity.* The energies will, in fact, be distributed over a large range from very small to very large, as indicated qualitatively, in Fig. 8.3; n(E)/n is the fraction of nuclei having energy E, per unit energy interval. If the energy distribution follows the Maxwell law, then the energy corresponding to the most probable velocity, per unit velocity interval, is equal to kT, where k is Boltzmann's constant; this is generally referred to as the energy corresponding to the temperature T.

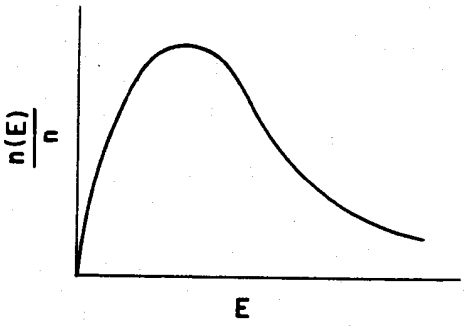

Fig. 8.3

As implied earlier, it has become the practice in the thermonuclear field to state the temperature as the energy kT, usually expressed in kev. Since k is 8.62×10^{-8} kev per degree, it follows that

$$\text{Temperature in kev} = 8.62 \times 10^{-8}\ T\ ,$$

where T is the absolute (Kelvin) temperature. Thus, a so-called temperature of 1 kev would correspond to a Kelvin temperature of 1.16×10^7 degrees.

*Since the energy E is kinetic, it is equal to $1/2\ mv^2$, where m is the mass of the nucleus; hence, v is determined by E, for a given species.

In order to determine the rate of a nuclear reaction at a given temperature, it is necessary to obtain a proper weighted average of σv, i.e., $\overline{\sigma v}$, over the whole energy range, since both σ and v vary with the nuclear energy. This can best be done by taking the experimental values of σ as a function of E (or of v), from Fig. 8.2, multiplying by the corresponding velocity, v, and then weighting each product according to the Maxwellian probability of that velocity. This operation may be expressed analytically by

$$\overline{\sigma v} = \frac{\int [\sigma(v)v]\ v^2 e^{-\frac{mv^2}{2kT}}\ dv}{\int v^2 e^{-\frac{mv^2}{2kT}}\ dv}, \qquad (8.5)$$

where the integrand in the denominator is the Maxwell factor. The values of $\overline{\sigma v}$ for one of the D-D reactions and for the D-T reaction, obtained somewhat in this manner, are plotted in Fig. 8.4 as a function of the temperature in kev. It is seen that, under equivalent density conditions, the D-T reaction is of the order of 50 to 100 times as fast as each of the D-D reactions at the same temperatures, at least in the range from 1 to 100 kev.

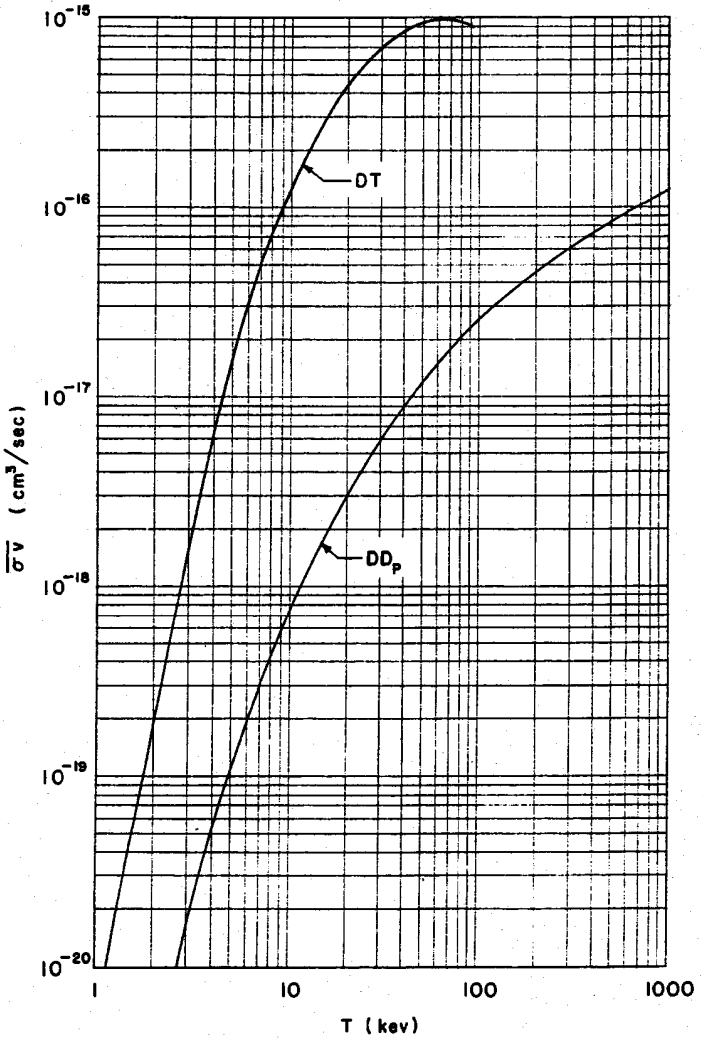

Fig. 8.4

The Reproduction Time

To illustrate the use of the data in Fig. 8.4, the energy reproduction time, i.e., the time required for the energy to double itself, in deuterium will be calculated. In every effective D-D collision, two deuterons are consumed, but in (roughly) half of these reactions a tritium nucleus is produced, which rapidly undergoes the D-T interaction with another deuterium nucleus. Thus, on the average, 2.5 deuterons are used up in every

effective collision.* From the arguments presented above, the number of effective D-D collisions is $\overline{\sigma v} N^2/2$ per cm^3 per sec, and so deuterons are consumed at the rate of $2.5\ \overline{\sigma v} N^2/2$ per cm^3 per sec. Since N is the number of deuterons present per cm^3, the fraction, F_t, of the deuterium reacting in time t sec is given by

$$F_t = \frac{2.5}{N}\ \overline{\sigma v}\ \frac{N^2}{2}\ t = 1.25\ \overline{\sigma v} N t\ , \qquad (8.6)$$

where t is assumed to be so short that N does not decrease appreciably.

If the two D-D reactions take place to, approximately, the same extent and every tritium nucleus formed rapidly undergoes the D-T reaction with another deuteron, the total energy liberated will be 4.04 + 3.27 + 17.6 = 24.9 Mev or, roughly, 25 Mev, for the consumption of five deuterons, i.e., 5 Mev or 5000 kev per deuteron. The energy ΔE produced in time t, per deuteron present in the system, is equal to F_t x 5000 kev, and so

$$\Delta E = 6250\ \overline{\sigma v} N t \text{ kev per deuteron.}$$

If E_{tot} is the total energy per deuteron present in the system, then the reproduction time, t_{rep}, i.e., the time required for the energy to double itself, due to the D-D and D-T reactions, is given by

$$t_{rep} = \frac{E_{tot}}{6250\ \overline{\sigma v} N}\ . \qquad (8.7)$$

DOE 5(3)

Production of Lithium-6

The enrichment of lithium-6, from its normal isotopic proportion of 7.3 per cent to the 95 per cent or so desirable for thermonuclear devices, is carried out by a chemical, isotopic exchange process. Lithium amalgam, consisting of a solution of metallic lithium in mercury, is allowed to interact with an aqueous solution of lithium hydroxide in water. As a result of the exchange between the lithium isotopes in the mercury and those present as ions in the water, the ratio of lithium-6 to lithium-7, at equilibrium, is larger in the amalgam than in the aqueous solution. The separation coefficient is not much greater than unity, and appreciable enrichment is achieved by a continuous counter-current process. The lithium amalgam, flowing in one direction, becomes steadily richer in the Li^6 isotope, whereas the proportion of lithium-7 increases in the hydroxide solution. Because of the separation difficulties, highly enriched lithium-6 is still rare and costly.

Clean H-Bomb Test Junked As U.S. Fears Mammoth Propaganda Dud

WASHINGTON (UPI) — The United States called off its planned show-the-world test of a "clean" H-bomb because the explosion was shaping up as a propaganda dud, informed sources said Wednesday.

There was even a possibility, according to government authorities, that the public shot could have backfired spectacularly against the United States in world public opinion.

The State Department announced cancellation of the test Saturday. The explanation given was that the earliest possible date for the shot had been pushed back by poor weather to late August. The department said that would interfere with attendance at the Geneva, Switzerland, conference on peaceful atomic energy starting Sept. 1.

Fourteen nations had been invited to witness the test. It was billed as a demonstration of a U.S. nuclear weapon of large destructive power—in the range of a million tons of TNT—with little radioactive fallout measured in elements believed dangerous to mankind.

Russia and Communist Czechoslovakia declined to attend. Only a handful of acceptances were received.

"Nobody was really interested in the test and the whole thing promised to be a dud," one source told United Press International. That appraisal was confirmed in informed quarters. One congressional informant said "hardly anybody" wanted to attend the demonstration shot.

Several sources suggested an added reason for the cancellation. This was rooted in the controversy over whether the radioisotope carbon-14, created by all nuclear blasts, is as dangerous as strontium-90 and other well-recognized fallout hazards.

Coast Guard Asks Position Of Raft

LONG BEACH, CALIF. (UPI) —The Coast Guard broadcast an appeal Tuesday for ships to report the position of the raft Lehi IV if it is spotted on its drifting trip to Hawaii.

The request was made more than two weeks after the raft was towed to sea from nearby Redondo Beach by the fishing boat "Redeemer of Israel."

ACKNOWLEDGEMENT

The preparation of this report has required the coverage of both considerable range and depth of technical detail. The work could not have been completed, especially in the time available, without the generous cooperation of many members of the Laboratory staff. It is impossible to mention the names of all who contributed in one way or another, but their invaluable help is gratefully acknowledged.

In the course of collecting material, I have been greatly impressed by the excellent morale and enthusiasm that prevail throughout the Laboratory. The general scientific atmosphere is undoubtedly responsible for the important progress in weapons development summarized here. In addition, it has made the preparation of this report a pleasure and a privilege.

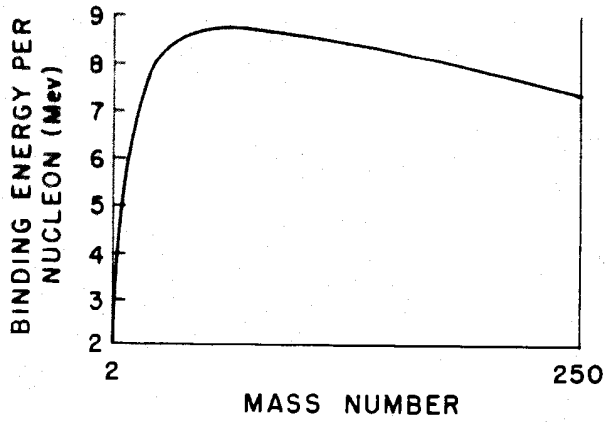

Fig. 1.1

A useful quantity is the mean binding energy per nucleon, i.e., B.E./A, where the mass number, A, is the number of protons and neutrons in the nucleus. The values of B.E./A for many nuclear species have been determined, from their known masses, and when plotted against the respective mass numbers, as in Fig. 1.1, the results are found to fall on, or very close to, a continuous curve. The significant aspect of this curve, for the present purpose, is that the mean binding energy per nucleon is less for the lightest and for the heaviest nuclei than it is for those of intermediate mass. It is this fact which accounts for the liberation of energy accompanying either the fission of heavy nuclei or the fusion of light nuclei, as can be shown in the following manner.

Calculation of Fission Energy

Uranium-235 undergoes fission in some thirty or more different ways, i.e., many different pairs of nuclei are formed. In the great majority of cases, however, the mass numbers of the fission products lie within the range from about 80 to 150, and from Fig. 1.1 it is seen that the average value of the binding energy per nucleon in this region is about 8.4 Mev. On the other hand, in the original uranium-235, the binding energy per nucleon is 7.5 Mev. Hence, the total energy which would be required to break up a uranium-235 nucleus into its 235 constituent nucleons would be 235 x 7.5 Mev, whereas for the fission product nuclei the corresponding energy would be about 235 x 8.4 Mev. In this calculation the neutrons involved in fission are neglected for simplicity, since they will have little effect on the final result. Consequently,

$$\text{Uranium-235} + (235 \times 7.5)\text{Mev} \longrightarrow 235 \text{ nucleons}$$
$$\text{Fission products} + (235 \times 8.4)\text{Mev} \longrightarrow 235 \text{ nucleons}$$

and upon subtraction and rearrangement it is seen that

$$\text{Uranium-235} \longrightarrow \text{Fission products} + (235 \times 0.9)\text{Mev}.$$

In other words, the fission of uranium-235 is accompanied by the release of 235 x 0.9 Mev, i.e., about 200 Mev, of energy.

For a specified shape and composition, the size of a critical system can be decreased by surrounding it with a material which scatters neutrons back into the fissile core. By reducing the number of neutrons that escape, a smaller size (or mass) can become critical. Such a scattering material, on account of its function, is referred to, in general, as a reflector. In nuclear weapons it is called a tamper, because, in addition to decreasing the loss of neutrons by escape, it delays expansion of the exploding mass and permits a higher yield from the system undergoing fission, as will be seen later.

As is to be expected, increasing the thickness of the tamper decreases the escape of neutrons and thus makes possible a smaller critical mass of the fissile (or core) material. However, it has been shown by theoretical calculations, and verified experimentally, that when the tamper thickness reaches a certain value there is little more to be gained by a further increase of thickness (Fig. 1.2). Thus, when the thickness is about two to three neutron mean free paths in the given tamper material, its effectiveness in reducing neutron losses is within 10 per cent or so of an infinitely thick tamper.

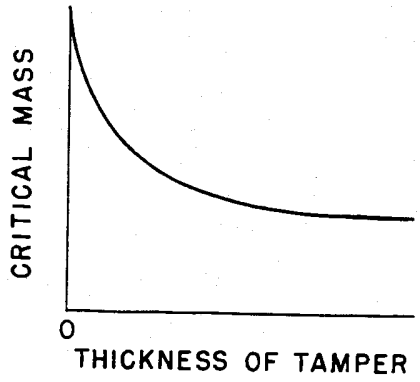

Fig. 1.2

Under precisely specified conditions, and for a given fissile (core) material, there is a definite mass that will be just critical. This is called a "crit." The critical masses of spheres of uranium-235 (94 per cent purity) and of plutonium-239 (97 per cent purity) are given in Table 1.3. In the first column are the values for a bare (untamped) sphere, whereas the values in the second column are for a thick (infinite) tamper of natural uranium metal. The effect of the tamper in reducing the critical mass of the core is very striking.

Table 1.3 Critical Masses of Spheres

Fissile Material	Bare	Tamped
Uranium-235	52 kg	17.2 kg
Plutonium-239	16 kg	5.8 kg

It may be noted that there is still another factor which affects the critical size: it is the speed (or energy) of the neutrons causing fission. The rate of the fission process is determined by the fission cross section, as will be seen later, and this varies with the neutron energy. However, as far as nuclear fission weapons are concerned, it may be tacitly assumed that only fast

neutrons, mainly with energies in the range from 0.5 to 2 Mev, are involved. Because of the relatively long slowing-down time, fission by slow neutrons would be less effective in an explosion.

1.3 Attainment of Criticality

Assembly Method (Gun-Type Weapons)

As long as a mass of fissile material is less than the critical value, i.e., it is subcritical for the existing conditions, there is no danger of a chain reaction occurring. But, if energy is to be released, e.g., in an explosion, the system must become critical and, in fact, highly supercritical, as will be seen shortly. There are two general ways, utilized in weapons, for rapidly converting a subcritical system of fissile material into one that is supercritical.

The first may be referred to as the method of assembly. Two portions of subcritical size are brought together very rapidly, so that the combined mass is supercritical. If a burst of neutrons is then introduced, a divergent fission chain will be initiated and there will be a rapid release of energy within a very short time. This is the principle used in weapons of the gun type: one subcritical portion of fissile material is shot into another subcritical portion, the combination exceeding the critical mass.

Compression Method (Implosion Weapons)

The second method of attaining criticality (or supercriticality) is based on compression of the subcritical fissile material. An approximate quantitative treatment of the relationship between the compression ratio and critical mass may be derived as follows. In accordance with the definition given above, the mean free path of a neutron is the average (crow-flight) distance a neutron travels before it interacts with a nucleus. The proportion of neutrons avoiding interaction, and which can consequently escape from the system, will evidently depend on the ratio of the dimensions, e.g., the radius of a sphere, to the mean free path. It is to be expected, therefore, that for a given fissile (core) material, under specified conditions, the critical radius will be approximately proportional to the neutron mean free path; thus, if R_c is the critical radius and λ_c is the mean free path in the core,

$$R_c \propto \lambda_c. \qquad (1.3)$$

The mean free path of a neutron is obviously inversely related to the probability of its interaction; the greater the probability of interaction, the smaller the distance the neutron will travel before it interacts with a nucleus. The probability of interaction is proportional to the number of fissile nuclei per unit volume, and hence to the density; so that, if ρ_c is the density of the core material,

$$\lambda_c \propto \frac{1}{\rho_c} . \tag{1.4}$$

The density of the material is dependent on the compression; thus, if C is the compression ratio, i.e., the volume before compression to that after,

$$C \propto \rho_c . \tag{1.5}$$

Combination of equations (1.3), (1.4), and (1.5) then leads to the result

$$R_c \propto \frac{1}{C} . \tag{1.6}$$

The critical mass M_c is related to the critical radius and the density of the material by

$$M_c = \frac{4}{3}\pi R_c^3 \rho_c , \tag{1.7}$$

and upon substituting equation (1.6) for R_c and equation (1.5) for ρ_c, it is seen that

$$M_c \propto \frac{1}{C^2} . \tag{1.8}$$

The critical mass of a given fissile material is thus inversely proportional to the square of the compression ratio. By increasing the compression the critical mass is consequently decreased.

It follows, therefore, that if a subcritical mass of fissile material is compressed it may become supercritical. [redacted] In other words, it will be highly supercritical, and the introduction of neutrons will cause a rapidly divergent fission chain to develop.

If the mass of fissile (core) material is tamped, then the result in equation (1.8) is true only if both the tamper and the core are compressed to the same extent. Actually, uniform compression is not attained throughout; it is greater near the center of the bomb, i.e., in the core, than further out, e.g., in the tamper. Even within the core itself there is a compression gradient. In general, therefore, the relationship between the critical mass and the average compression ratios of the core (C_c) and of the tamper (C_t) may be represented by

$$M_c \propto \frac{1}{C_c^{1.2}} \cdot \frac{1}{C_t^{0.8}} , \tag{1.9}$$

so that when C_c and C_t are identical, this reduces to equation (1.8). For most cases of interest in the weapons field, a good approximation is

$$M_c \propto \frac{1}{C_c^{1.7}} , \tag{1.10}$$

since the conditions are such that the tamper is compressed to a smaller extent than is the core.

The use of compression to attain supercriticality is employed in weapons of the implosion type; the reason for this name will be seen later. Not only does increased compression result in a decrease in critical mass, it is also accompanied by an increase in efficiency of the energy release, as will be seen in Section 2.1. Consequently, the attainment of higher and higher compressions is one of the important objectives of weapon development.

1.4 Neutron Multiplication

Rate of Fission Reaction

No matter how it originates, an explosion involves the very rapid liberation of a large amount of energy. If the energy is to be produced by fission, then the necessary condition is a very high neutron density, since the rate of fission, and, hence, the rate of energy release, is proportional to the number of neutrons per unit volume. It is of interest, therefore, to investigate the circumstances which lead to a high neutron density.

It was seen earlier that the number of neutrons available to cause fission, for every neutron captured in a fission process, in each generation is equal to k, i.e., to $\nu - \ell$, where ν is the average number of neutrons produced per fission and ℓ is the average number lost by escape and nonfission capture. This means that for every n neutrons present at the beginning of a generation, there will be nk present at the end, so that the gain of neutrons is n(k - 1) per generation. The rate of gain, dn/dt, may then be obtained, roughly, upon dividing the actual gain by the average time, τ, between successive fission generations; hence,

$$\frac{dn}{dt} = \frac{n(k-1)}{\tau} . \tag{1.11}$$

This result will be strictly correct only if the delayed neutrons play no significant part in maintaining the fission chain. As seen above, this condition is applicable to nuclear fission weapons.

The quantity k - 1, which is the excess number of available neutrons per fission, may be

1.5 Production of Weapon Materials

Uranium-235

The two important fissile materials, namely, uranium-235 and plutonium-239, are both produced from natural uranium but by entirely different procedures. Ordinary uranium contains about 0.7 per cent of uranium-235 to 99.3 per cent of uranium-238, and a trace (0.006 per cent) of uranium-234. The uranium-235 is separated by diffusion (through porous barriers) of the vapor of uranium hexafluoride (UF_6), made from natural uranium. The hexafluoride of the lighter isotope diffuses more rapidly than does that of the heavier species, and by the use of several thousand diffusion stages an enrichment of 93.5 per cent, i.e., a material containing an isotopic proportion of 93.5 per cent of uranium-235, can be obtained. The highly enriched uranium hexafluoride is then converted into the tetrafluoride (UF_4) by heating with hydrogen or methane. The uranium tetrafluoride is reduced to metal by means of calcium plus some iodine to act as a "thermal booster." Reaction between iodine and part of the calcium starts at about 400°C; the heat generated raises the temperature sufficiently for rapid reduction of the tetrafluoride by calcium to take place.

Plutonium-239

The element plutonium occurs in nature as virtually insignificant traces, at best. Consequently, the plutonium-239 used in weapons is obtained artifically by a series of nuclear reactions resulting from the exposure of uranium-238 to slow neutrons in a nuclear reactor or "pile." A nuclear reactor is a device in which a fission chain reaction is taking place in a controlled manner. If a material of low mass number, called a moderator, is present, in addition to fissile material, the fission neutrons will be slowed down, and such a system is, in a sense, a source of slow neutrons.

In a reactor, uranium-238 captures neutrons to form a higher isotope, uranium-239, with the emission of gamma radiation; thus

$$_{92}U^{238} + {}_{0}n^{1} \longrightarrow {}_{92}U^{239} + \gamma,$$

where the subscripts give the atomic numbers, i.e., number of protons, and the superscripts indicate the mass numbers, i.e., total number of neutrons and protons in each case. The uranium-239 is radioactive, with a half life of 23 min, emitting a beta particle. Representing the latter by $_{-1}\beta^{0}$, since it carries a negative charge and has essentially no mass, the radioactive decay process may be written as

$$_{92}U^{239} \longrightarrow {}_{-1}\beta^{0} + {}_{93}Np^{239},$$

SECRET

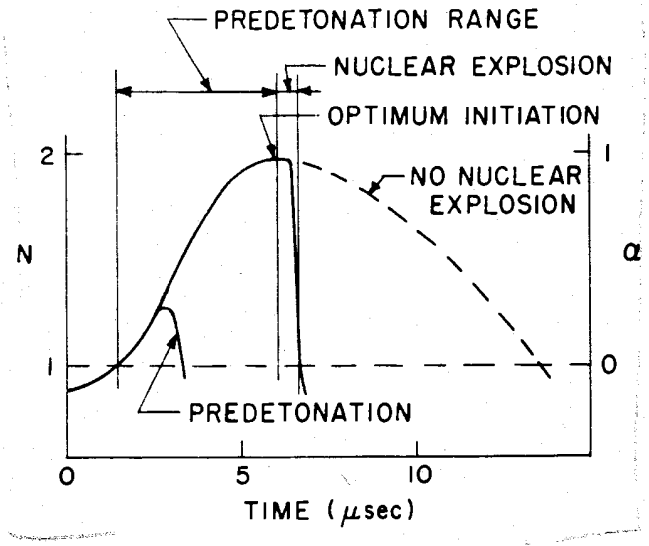

Fig. 2.2

rate, and the abscissae are elapsed time from the beginning of the assembly of a gun-type weapon or compression of an implosion weapon. The numerical values given for N and α are not exact and are intended merely as an indication of the changes which occur. The times, on the other hand, are fairly representative of an implosion weapon. The horizontal dotted line represents the situation for a system that is just critical, i.e., $N = 1$, $\alpha = 0$. Actually, the curves for N and for α as functions of time are somewhat different, and the maxima do not necessarily coincide. However, for the present qualitative discussion, a single curve is adequate.

At zero time the fissile material is subcritical, i.e., $N < 1$, and α is negative, but as compression (or assembly) occurs the value of N increases and α becomes positive, i.e., the system becomes supercritical. If, for some reason, there were no nuclear explosion, the fissile material would suffer decompression, due to its elasticity, after reaching the compression maximum, as indicated by the broken line in Fig. 2.2. In the case of a gun weapon, the parts may fly apart due to the impact.

The optimum yield will obviously be obtained if initiation occurs at the maximum of the curve, i.e., when N has its maximum value. It is at this instant, a few microseconds after compression starts, that the chain should be initiated by the special neutron source. In this event, the whole nuclear explosion will be over in 0.25 to 0.75 μsec, as stated in Section 1.4.

If a neutron entered the core in the period between that at which $N = 1$, $\alpha = 0$ and the maximum of the curve, i.e., while the system is supercritical but before maximum supercriticality is attained, an explosion would occur, but since N would not be as large as is possible, the efficiency will be low. Thus, in order to attain the highest efficiency, predetonation must be avoided. The same will also be true, of course, for postdetonation, i.e., initiation after the maximum of compression has been passed.

The variation of yield with time of initiation may be calculated by any of the methods given above for the determination of efficiency. All that is necessary is to introduce the values of N, α, ρ, etc., which are appropriate to the explosion time in each case. The values

b(3)

When the shock wave produced by the detonation of the HE inner charge enters the tamper, the latter moves forward, with the attached pusher, through the air space with increasing velocity. As a result, when the tamper reaches the core, it strikes the latter a tremendous, hammer-like blow. More energy is thereby transferred to the core, which is consequently more highly compressed than would be the case in the absence of a free run.

Recovery of Plutonium and Oralloy

Because of their value as fissile materials, all residues of plutonium and oralloy are carefully collected for recovery. Plutonium in the form of metal, e.g., turnings, filings, etc., or of oxide, formed in casting, is dissolved in nitric acid with a little hydrofluoric acid. From the resulting nitrate solution (or slurry), plutonium peroxide is precipitated by hydrogen peroxide and sent to the plutonium production line. Magnesium oxide crucibles and molds and the calcium fluoride-iodide slag remaining from the metal reduction stage are dissolved in nitric acid containing aluminum nitrate. The plutonium is then recovered either by direct extraction in tributylphosphate (TBP) diluted with kerosene, or extraction after an intermediate stage involving volume reduction by precipitation of the plutonium with calcium oxalate as carrier. Organic matter such as clean-up paper, rags, etc., are first incinerated and the residual ash is then treated as just described.

Oralloy turnings and oxide residues are dissolved in nitric acid and after two stages of precipitation with hydrogen peroxide, to insure high purity, the resulting uranium peroxide is converted mainly to U_3O_8 by heat and is then reduced by hydrogen to the dioxide, UO_2. The action of hydrogen fluoride gas converts this to the tetrafluoride and the metal is finally obtained by heating with calcium. Magnesium oxide crucibles, slag, and other residues are treated in a manner similar to that used to recover plutonium. The materials are dissolved in nitric acid with aluminum nitrate and the uranium is extracted by means of TBP in kerosene.

5.5 External Initiators

b(3)

One problem in the use of an externally activated initiator is that of precise timing. For this purpose, it is necessary to know the transit time of the bomb, from the triggering of the X-unit to the time the implosion shock wave reaches the center of the core.

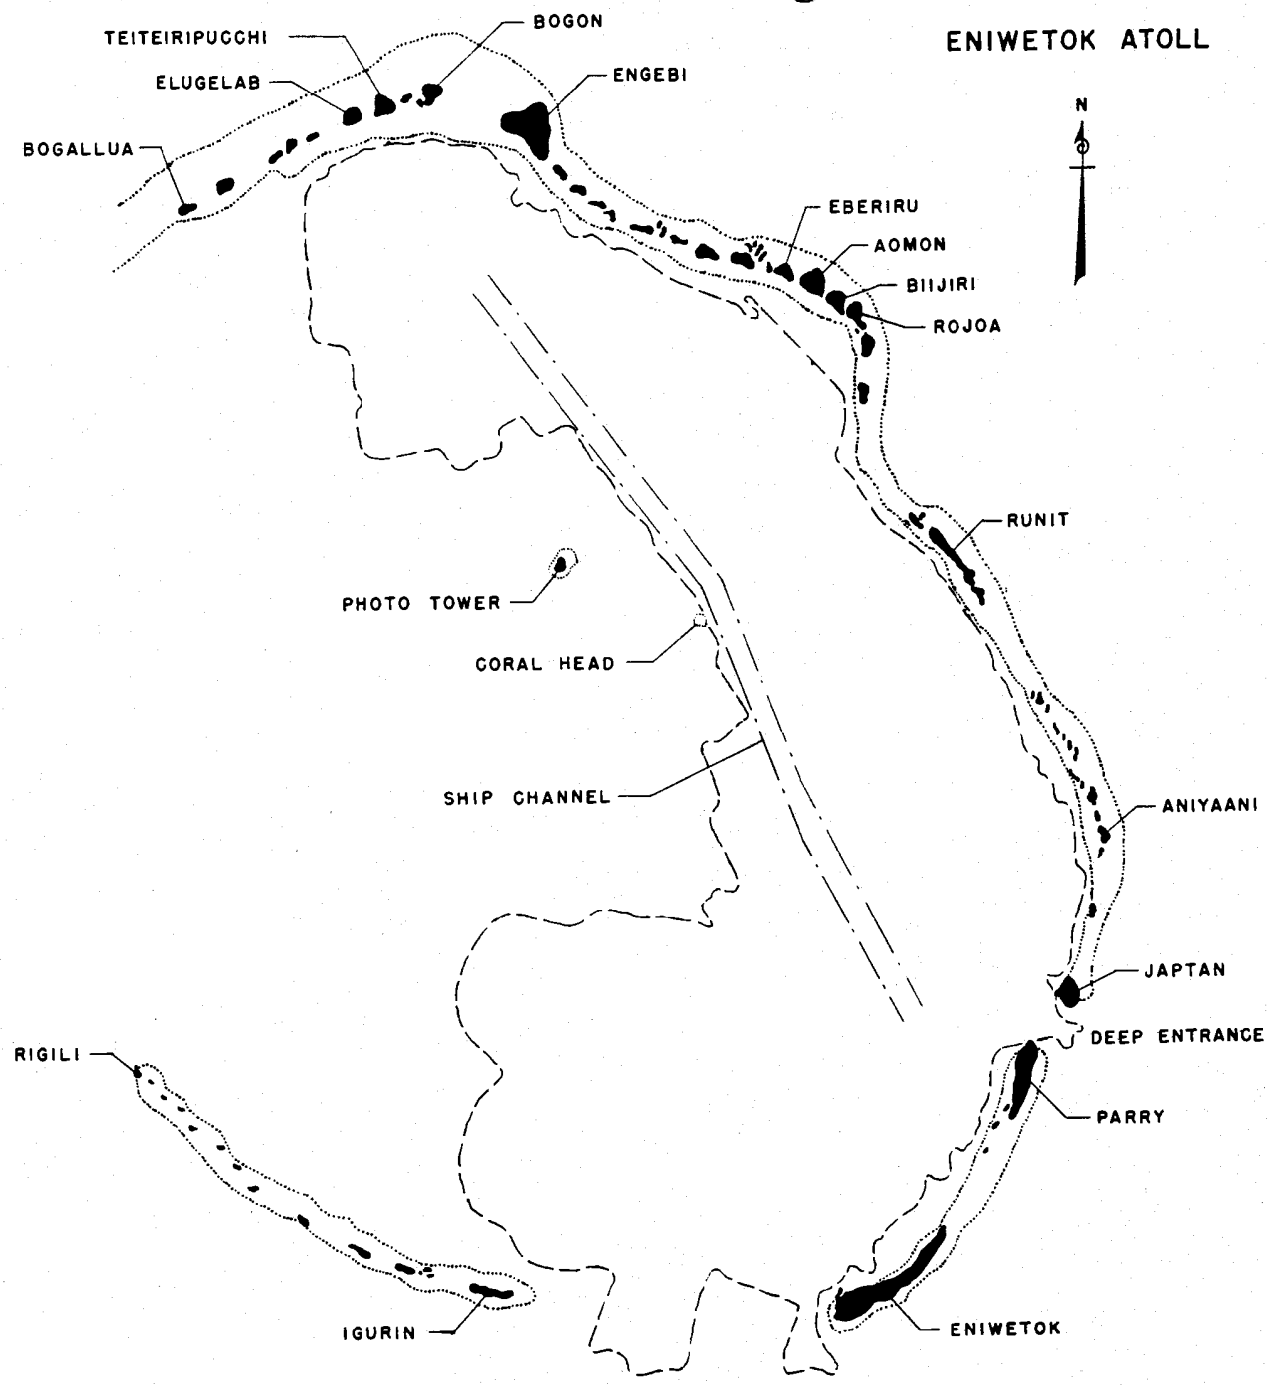
b(3)

UNCLASSIFIED

b(3)

UNCLASSIFIED

The ENS Initiator



The new external initiator, called the ENS (Experimental Neutron Source), makes use of the fact that 14-Mev neutrons are released in the T-D reaction, between tritium and deuterium nuclei. However, the energy required to make the reaction take place is here supplied by accelerating tritium ions (tritons) in an electrical field; these high-energy ions then impinge upon, and react with, deuterium nuclei.

b(3)

reaching a detecting instrument on the ground will cover a large range of energies. The distribution of the neutrons in this manner is referred to as the neutron spectrum. Those neutrons which have not been scattered have high energies, e.g., 3 Mev or more; others have energies in the intermediate range, while the great majority are slow neutrons. However, because of capture by nitrogen nuclei, very few have energies below about 0.2 ev.

b(3)

The proportion of neutrons produced in fission with energies as high as 14 Mev is very small, but if the D-T reaction is involved, a considerable number of neutrons of this energy will be detected.

6.4 Diagnostic Tests

Determination of Transit Time

A very great variety of measurements are usually made for each test shot, many of which depend upon the particular information required. However, for essentially all fission weapons the so-called standard diagnostic tests are made; these are the determination of the over-all transit time, the multiplication rate (α), and the energy yield of the device. Although yield measurements are always made, determinations of transit time and α are sometimes omitted. Apart from providing useful practical information, the results of the diagnostic tests serve to check theoretical estimates and to supply data upon which further calculations may be based.

For the measurement of the over-all transit time, i.e., from the instant of firing the detonators to the explosion time, two general methods have been used. In the case of a tower shot, a signal is sent over a coaxial cable to a distant cathode ray oscilloscope when the X-unit is fired. The first gamma rays to appear outside the bomb are picked up by a scintillation detector and a second signal is transmitted by cable to the oscilloscope. After making allowance for the difference in lengths of the cables and the time taken for the gamma rays to reach the detector, the transit time of the bomb can be determined from the separation of the two signals.

The procedure described above, which requires cable connections to the X-unit, cannot be used for an airdrop, and in this event the remote method is employed. A radio transmitter, operating at low power, e.g., about 20 watts, is attached to the bomb case. When the X-unit is fired, the output is instantaneously raised to several hundred watts, so that the signal can be detected at a distance and recorded on an oscilloscope. This continues until the intense ionization of the atmosphere, referred to as the "ion curtain," in the vicinity of the bomb, due to the gamma radiation, prevents further propagation of the radio signal. The level at which

this transmission is cut off is not known exactly, but it is believed to be at about the 30th generation, or so. Allowance for this delay is made in estimating the transit time from the duration of the radio signal. If the generation time is relatively long, e.g., for low values of α (Section 1.4), this correction may involve an appreciable error.

Determination of Alpha

Until recently, only one satisfactory method was available for determining the multiplication rate, α; it was based on a measurement of the time-dependence of the prompt gamma rays over a period of about 1 μsec. It can be seen from equation (1.16) that α can be determined if the neutron density, n, in the exploding bomb is known as a function of time. As seen above, the prompt gamma rays are produced, almost entirely, by the action of neutrons within the bomb. Hence, the prompt gamma-ray intensity, fairly close to the bomb, may be taken as being proportional to the neutron density. Consequently, α can be readily calculated from the variation of the prompt gamma rays with time.

Originally large (Rossi-type) ion-chambers, having a fast response, were used to detect the gamma rays, but these have now been replaced by scintillation detectors. The latter are located near the bomb, in the case of a tower shot, and long coaxial cables connect them to the horizontal plates of an oscilloscope. A constant, high-frequency sinusoidal signal applied to the vertical plate supplies a timing record. The oscilloscope trace is photographed and then analyzed to give the time dependence of the prompt gamma-ray intensity. By the use of additional cable, the gamma-ray signal is delayed, so that an intensifier pulse to the oscilloscope can build up and thus permit the trace to be photographed.

In order to cover the large range of intensity, several scintillation detectors may be placed at various distances from the bomb. A common timing system is sometimes used for all the oscilloscopes to which they are connected. The detectors nearest to the explosion record the lower intensities of gamma radiation, whereas those which are more remote indicate the higher intensities. Proper allowance is made, of course, for the attenuation with distance.

For an airdrop the scintillation detectors cannot be placed near the bomb. Consequently, they are located on the ground at known distances from the assumed detonation point. Because of the absorption of the radiation, the intensities at the detectors are relatively small and for high bursts amplifiers may have to be used.

b(3)

Another procedure for obtaining α, which avoids destruction of the detectors, etc., and can be used either for tower shots or airdrops, was first tried out at Operation Sandstone, but did not reach a satisfactory state of development until the Upshot-Knothole test in 1953. One

of its great advantages is that measurements can be made at a distance of 10 miles or so, where the instruments are under direct control, and no coaxial cables are necessary.

When the prompt gamma rays are degraded in energy and absorbed by the air around the bomb, they produce a luminosity, called the Teller light. The intensity of this light is proportional to that of the prompt gamma rays and, consequently, to the neutron density.

b(3)

It is essential that the only light measured should be that coming directly from the bomb to the observer.

In one arrangement for recording the luminosity at very low levels, without the necessity of amplification of signals, the Teller light from the bomb is reflected by a mirror system (Fig. 6.5) and falls on the photomultiplier tube. This is placed as close as possible to the deflecting plates of a cathode-ray oscilloscope tube in a light-tight box. The timing and delay circuits are analogous to those used in the method already described. To provide a wide field of view, the mirrors are in duplicate; consequently, a moderate change in the expected position of the exploding bomb will not affect observation of the Teller light.

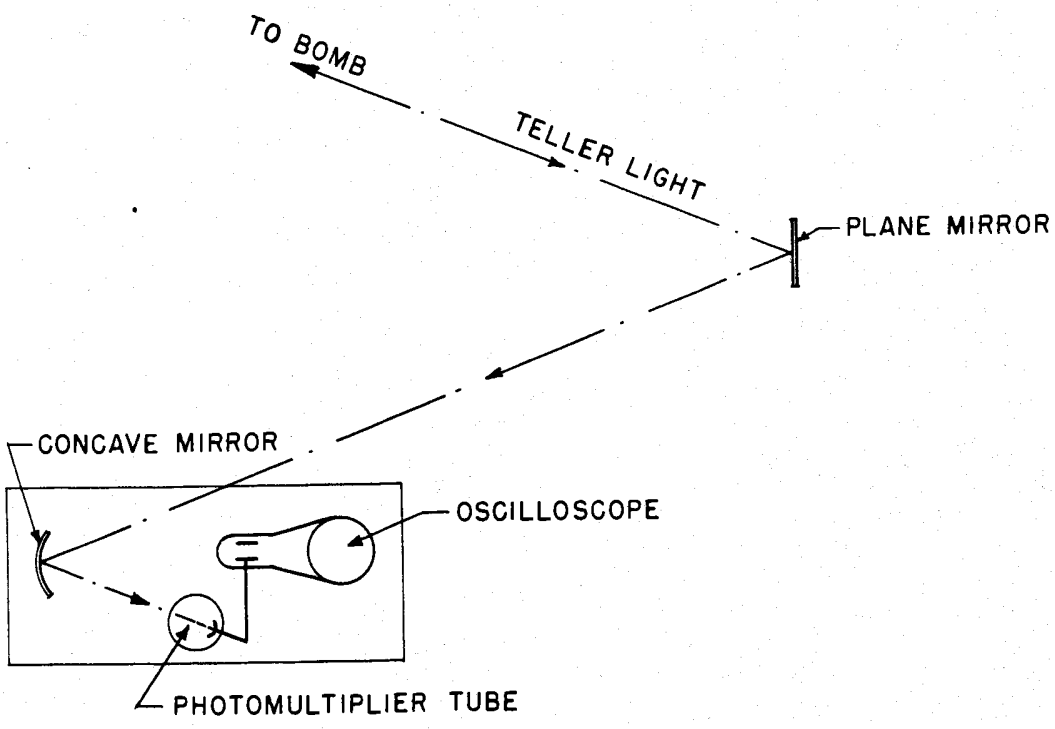

Fig. 6.5

The fission products which have been used most extensively in efficiency measurements are molybdenum-99 (half life 67 hours) and zirconium-97 (half life 17 hours). These isotopes have convenient half lifes, and their fission yields, which are among the largest, are not greatly dependent upon the energy of the neutrons causing fission. The λy values for molybdenum-99 are almost identical for fission of uranium-235 and plutonium-239, so that no correction is necessary if the bomb core contains both of these fissile species. For this and other reasons, molybdenum is the preferred isotope. For zirconium, the λy's are slightly different and the value used to determine f depends upon the composition of the core.

The fraction θ of the bomb in the post-shot sample can be determined by analyzing for one of the major constituents, e.g., uranium-235, plutonium-239, or total uranium, and correcting for the amounts lost in nonfission reactions, such as (n,γ), (n, 2n), etc. Since the total amount of each of these species present in the original bomb is known, the fraction of the bomb in the sample can be calculated.

Another method for determining the fraction of the bomb in the post-shot sample makes use of a different principle. A radioactive tracer, in known amount, is included in the bomb before detonation. If the quantity present in the post-shot sample is then measured, the fraction of the bomb in the sample can be calculated. The supposition is here, of course, that the tracer is uniformly distributed throughout the whole of the bomb residues, and this may not be the case. Measurements of this kind have been made with polonium-210 as tracer, but with indifferent success. Nevertheless, it is proposed to make further determinations with this isotope and also with curium-242 as tracer.

Determination of Fraction of Fissions in U-235, Pu-239, and U-238

It is of interest to know what proportion of fissions has occurred in uranium-235, plutonium-239, and uranium-238, respectively. Radiochemical methods have been developed for this purpose, although they are not too accurate. The fraction of the total fissions involving uranium-235 is represented by a, the fraction in plutonium-239 by b, and that in uranium-238 by c, so that

$$a + b + c = 1. \qquad (6.5)$$

Hence, if any two of a, b, c are determined, the third is known.

The value of c can be obtained by utilizing the experimental fact that the ratio of the cross section for the U^{238} (n, 2n) U^{237} reaction to that for the fission of uranium-238 is roughly constant, independent of neutron attenuation in the uranium. Hence, if the amount of uranium-237 in the bomb residue sample is measured, by means of its radioactivity, the number of uranium-238 nuclei which have undergone fission, and hence, c, can be calculated.

same in both cases, and appropriate corrections must be made for any differences.

According to the theory of strong shocks, the rate of propagation of the shock front and, hence, in the present case, the rate of increase in the radius or diameter, D, of the ball of fire, is given by

$$D = kt^n, \tag{6.8}$$

where k, for a particular bomb, is a constant related to the yield,* and the exponent n is dependent upon γ, the ratio of the specific heats of the material at the shock front. When γ is 1.4, the value of n is close to 0.4, and then equation (6.8) can be written as

$$D = kt^{0.4}. \tag{6.9}$$

It appears that k is roughly proportional to $Y^{1/5}$, so that a good approximation when n is 0.4, has been found to be

$$Y = C\rho_o k^5 = C\rho_o \frac{D^5}{t^2}, \tag{6.10}$$

where C is a constant determined from observations on the balls of fire produced by bombs of known yield; ρ_o is the density of the ambient air.

To use equation (6.10) for the determination of yields, the data for D at various times t, obtained from the Rapatronic camera films, are plotted and the point found at which n in equation (6.8) is 0.4. Upon substituting the corresponding values of D and t into equation (6.10), the yield can be calculated.

Recently a new, absolute (analytic) method for obtaining yields, independent of scaling principles or knowledge of yield of other bombs, has been developed. It permits the calculation of the total energy produced in the nuclear explosion at any time up to breakaway, using hydrodynamic and thermodynamic principles. According to this method, which takes into account such factors as the transport of radiation in the early stages of the development of the shock front, the large mass of the bomb, and time variations in the equation of state of air and in the ratio of the specific heats at the shock front, the yield may be represented by

$$Y = \frac{F}{32}\rho_o n^2 \frac{D^5}{t^2} \tag{6.11}$$

*The factor k is generally represented by ϕ, but this symbol is used here for the efficiency.

SECRET
UNCLASSIFIED

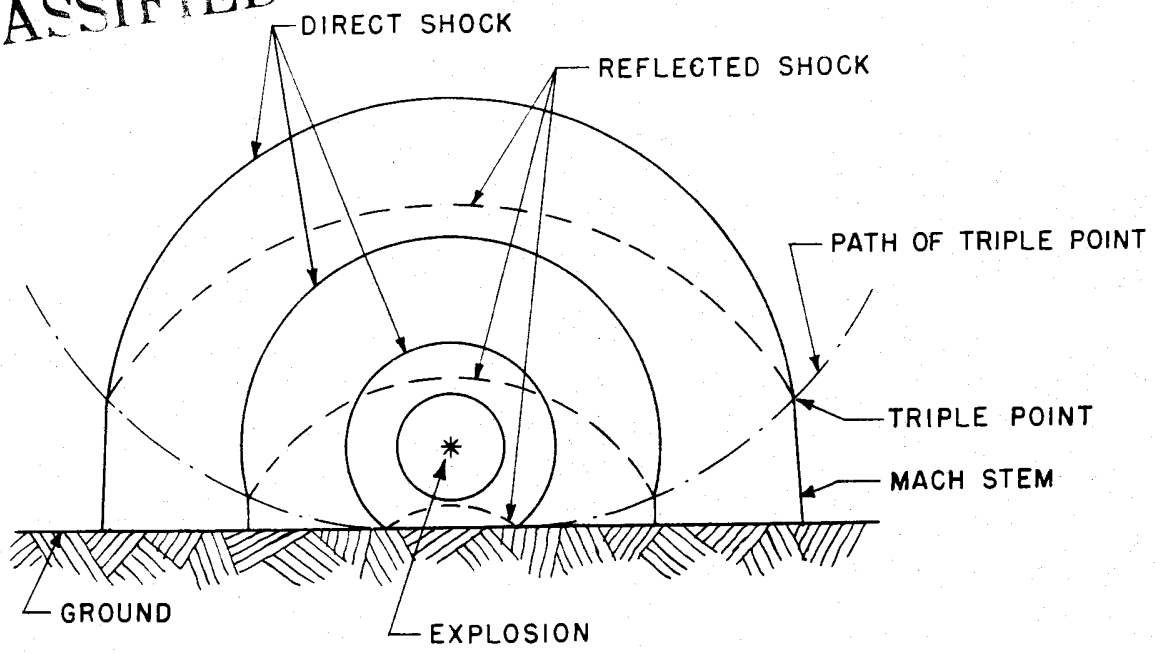

Fig. 6.7

Free-Air Peak Pressure

The shock pressures in the air above the triple point path, i.e., where the Mach effect is not apparent, are called the free-air pressures; these can be determined by observing the time of arrival of the shock front at a series of points at known distances from the explosion. From these times of arrival the shock velocity can be determined and the maximum or peak pressure at various distances can then be calculated from shock-wave theory.

One method used for observing shock arrival times was to attach blast switches to a number of cables held by balloons. Upon arrival of the shock, the switch closes and sends a signal to a distant receiving station, by cable or radio. This procedure has been found to be rather expensive and so it has been replaced by the method of rocket-trail photography.

In passing through a region occupied by a shock front, light is refracted, so that objects seen through the shock wave appear to be distorted; this fact permits times of shock arrival to be determined. Just prior to the explosion, a fan-like grid of vertical smoke trails is produced from a number of rockets launched from the ground at various distances from the zero point. These trails are photographed with a motion-picture camera, at about 100 frames/sec. The arrival of the shock front at a point between the camera and any trail is indicated by an

UNCLASSIFIED
SECRET

apparent shift in position of the trail due to refraction. The method can be used to determine shock pressures as high as 10,000 psi.

Material Velocity Measurements

Material velocity or mass-motion studies have been found to be a useful means of determining free-air peak pressures as a function of distance and also as a means for studying many hydrodynamic variables associated with shock waves. The general principle of the mass-motion method is to label a parcel of air with smoke and then to record photographically, with a motion-picture camera, the movement of the visible cloud when struck by the shock wave. From the displacement of the cloud and the camera speed, a displacement-time curve can be obtained. The maximum slope of this curve gives the material velocity associated with the peak shock pressure. Then from the shock-wave theory, this pressure can be calculated. The mass-motion procedure is probably most valuable at distances where the shock pressure is not too high.

Three methods have been found satisfactory for labeling a region of the air with smoke. These are, first, the use of a jet-assisted take-off (JATO) unit on the ground, with its nozzle pointing upward. Upon ignition this produces a vertical column of white smoke, extending for about 150 feet, which can readily be photographed. The second method utilizes aerial, fireworks bombs ("aerial salutes"); these are fired vertically from a mortar and produce a visible puff of smoke at 100 to 350 ft in the air. Finally, for considerable heights above the ground, smoke shells, fuzed to explode at the desired altitude, are shot from a 90-mm antiaircraft gun.

Mach-Region Peak Pressures

The rocket-trail method described above has been found to give information concerning the Mach triple point path and the shape of the Mach stem in its early stages, as well as of pressures in the Mach region. For studies at or near ground level, arrival times can be determined by means of blast switches or by various methods of direct pressure measurement. Such direct observations are usually restricted to shock pressures below about 100 psi. Several types of pressure gauge have been used for this purpose with more or less success. Mention may be made of foil, indenter, and Wiancko gauges.

The foil meter has a series of thin metal diaphragms of different diameters, so that different pressures are required to rupture them. The maximum diameter not ruptured indicates the maximum shock pressure at that point. In the indenter gauge, the pressure is determined from the indentation produced in a sheet of copper. However, at the present time it is believed that the Wiancko guage, which is a modification of the Bourdon pressure gauge, will prove most satisfactory.

fireball surface, is of special interest. This has been referred to in Section 6.3 as the prompt or effective thermal radiation. The latter description is applied because it is this radiation which is responsible for skin burns, and possibly of fires out to considerable distances from a nuclear explosion. Prompt thermal radiation studies are thus of interest, not only because they provide information concerning the phenomena of a nuclear explosion, but also because of the importance of these thermal radiations from the weapons standpoint. Measurements are usually made of the total energy released as prompt thermal radiation and of the energy variation with time.

The total prompt thermal radiation is measured in two ways. One method makes use of a conventional ballistic thermocouple, the output of which is measured with a thermopile recorder connected to a photoelectronic galvanometer. In the other method a blackened container is filled with air which expands, due to the temperature increase, when radiation is absorbed. The amount of the latter is calculated from the movement of a diaphragm indicator. By using data for the transmission of radiation by the atmosphere just prior to the explosion, such as those described earlier, the total energy liberated by the bomb as prompt thermal radiation can be estimated.*

It was thought at one time that a definite fraction of the energy of the explosion appears as prompt thermal radiation. More recent measurements have shown, however, that this fraction varies with the bomb yield. The results can be expressed, to a fair degree of accuracy, by the relationship

$$Y_{th} = 0.42Y^{0.9 \pm 0.04} \qquad (6.14)$$

where the prompt thermal radiation yield, Y_{th}, and the total bomb yield, Y, are expressed in kilotons. It follows, therefore, that for a 20 kt bomb about 28 per cent of the energy is released as prompt thermal radiation, but in a 100 kt bomb the proportion is only 23 per cent.

The amount of radiation energy, Q, delivered per unit area at a distance D from the explosion is represented by

$$Q = \frac{Y_{th}}{4\pi D^2} e^{-kD} \qquad (6.15)$$

where k is the attenuation coefficient of the air for the thermal radiation emitted in the explosion. The value of k, which determines the transmission of radiation, depends on the state

*The transmission coefficient depends to a marked extent on the wavelength of the radiation and this must be taken into account in the calculation.

Because of the very short exposures, the attenuation of light between the ball of fire and the camera, several miles away, is very important. It is necessary, therefore, to monitor the light path prior to the test shot, by the method already described, if high-speed photography is to be used for ball-of-fire measurements.

Rotating Mirror (Streak) Cameras

The rotating mirror, streak cameras used in weapons tests are essentially the same as those described in Chapter 4 for testing detonators and HE lenses. A rotating mirror reflects light continuously from a number of sources on to a film strip; the distance between the points at which the traces from the different sources commence is a measure of the time interval between the initiation of the respective sources. The writing speed is such that 2 mm is equivalent to 1 μsec. The essential purpose of the streak cameras in weapons tests is thus to determine elapsed time between two or more events.

One such use is to measure the time interval between the fission and fusion reactions in separate parts of a two-stage thermonuclear device. Each type of process will induce Teller light (see Section 6.4) in the surrounding air, so that two streaks will appear on the camera film. The distance between the beginning of the two streaks gives the time between the two reactions.

Another application of the rotating mirror, streak camera is to determine shock velocity and pressure within a device by studying so-called "hot spots." These are points (or small areas) down the length of a case at which the arrival of the shock front from a fission bomb is indicated by strong light emission. By means of a pipe and mirror arrangement, the camera observes only certain selected points, the light from all other parts of the bomb being blocked out. From the positions of the streaks indicating the arrival of the shock front at successive points a known distance apart, the velocity and shock wave and, hence, the shock pressure can be calculated.

The propagation of the shock wave through a particular metal, which is part of the bomb case, can also be studied by the hot-spot procedure. This is done by making the shock wave traverse different thicknesses of the metal, by drilling the bomb case at some points and adding pads of the same material at others. The various spots will thus become luminous at different times and the intervals between them can be estimated from the camera streaks.

6.10 Thermonuclear Burning Studies

Tenex Measurements

The primary purpose of the Tenex (temperature neutron experiment) measurements is to make use of the 14-Mev neutrons produced in the D-T reaction to estimate the thermonuclear

SECRET

UNCLASSIFIED

burning temperature. Strictly speaking, these neutrons have an energy of 14 Mev only if the reacting deuterium and tritium nuclei are at rest. But if these nuclei are in motion, the neutron energy will be 14 Mev plus four fifths of the kinetic energy of the reacting particles in the center-of-mass (C-of-M) system. Actually the center of mass is in motion relative to the observer, so that there is a Doppler energy shift superimposed on the energy in the C-of-M system. Consequently, neutrons released in the D-T reaction will have energies covering a band in the vicinity of 14 Mev. The higher the velocity of the particles, i.e., the higher the nuclear temperature, the broader the band. The velocity distribution is roughly Gaussian, with the half width depending on the temperature.

A scintillation detector is placed at a considerable distance from the explosion, so that neutrons of different energies belonging to the 14-Mev group arrive at different times. These are recorded on a synchroscope, and the velocity distribution can then be determined from the observed "times of flight." From this distribution, the temperature of the thermonuclear reaction system can be estimated. *

When studying thermonuclear devices of high energy yield, the recording instruments must be located a considerable distance away. If the detectors can be placed near the explosion point, long cables are necessary to transmit signals to the recorders. Such lines must be protected from extraneous gamma radiations by extensive earth fills which are costly. On the other hand, if the detectors are close to the recording instruments, the radiations from the bomb, e.g., neutrons and gamma rays, suffer considerable attenuation due to absorption, so that weak signals are received.

In the Ivy tests the problem was solved by transmitting the radiations through a helium channel since this gas is a poor absorber for both neutrons and gamma rays. The channel consisted of a plywood box, 8 ft by 8 ft in cross section and nearly 9,000 ft long, filled with a number of thin-walled polyethylene balloons containing helium gas at slightly above atmospheric pressure. Lead baffles inserted in the box served to provide a number of well-collimated paths, which were used for Tenex and other measurements related to thermonuclear burning.

In order to reduce attenuation still further, an evacuated metal pipe, 6 inches internal diameter and about 7,500 feet in length, is to be used as the radiation path in the Castle tests. A pressure of 0.1 atm is believed to be adequate for the purpose, although it is expected that a much higher vacuum will be maintained.

---

*The energy distribution can also be determined, and the temperature estimated, by the Phonex measurements described in Section 6.6.

UNCLASSIFIED

SECRET

Gamma-Ray Experiment

A method for studying the time characteristics of D-T burning makes use of the gamma radiation accompanying the reaction. In this experiment it is essential that the gamma-ray beam should be well collimated and that the collimator should point at the region of the bomb where the thermonuclear processes are occurring. The gamma rays are observed by means of a scintillation detector connected to an oscilloscope; the time variation of the observed signal is then directly related to the progress of the thermonuclear burning.

For the George experiment (Operation Greenhouse) the detector was placed near the device and the signal was carried by buried cables to the oscilloscope which was not too far away. In the Mike (Ivy) shot, however, for the reasons given above, the gamma radiation was transmitted through a collimated channel in the long helium-filled box described earlier. For the Castle tests, the vacuum pipe referred to above will be used.

X-Ray Experiment

Nuclear reaction temperatures can be determined by utilizing the fact that at these temperatures the "thermal" radiation emitted is in the soft X-ray region, with energies in the range from 1 to 10 kev. From the energy or wavelength of this radiation, it is possible to estimate the temperature of the emitter. The method is usually not applicable to fission bombs because of the considerable absorption of the X-rays by the bomb materials. But for certain thermonuclear devices, where the absorption is not so great, the X-ray method can be used to derive reaction temperatures.

There are several difficulties associated with the measurements, among which may be mentioned the following: the 1 to 10 kev region has been little studied; a very high time resolution is required because of the rapidity of the thermonuclear burning; and the detecting devices must cover a wide range of intensities. The method used with some success at the Greenhouse tests was to permit the "thermal" X-radiation from the experimental device to travel down an evacuated pipe and to fall on a detector, called a fluorescer. This is a foil coated with a compound of either potassium, manganese, or copper; these elements are sensitive to X-rays in the regions just above 3.6, 6.5, and 9.0 kev, respectively.

If X-rays of the appropriate energy strike the fluorescer, one of the K-electrons of the element present will be ejected; when its place is taken by another electron, the characteristic K-radiation of either potassium, manganese, or copper will be emitted. This is allowed to fall upon an aluminum surface shielded from the direct X-ray beam, and as a result photoelectrons are produced. The electrons are accelerated by a high voltage and the resulting signal can be recorded on an oscilloscope. By observing which of the fluorescers produces its characteristic X-radiation, an estimate may be made of the energy of the primary (thermal) X-rays and hence of the temperature of the material emitting them.

40% Li6, 60% Li7; 52% fission

hydrogen bomb should or should not be developed, the President directed the Atomic Energy Commission to continue its work on all forms of atomic weapons, including the so-called hydrogen or Super bomb. Work on Super was accordingly accelerated, only to be retarded again in mid-1950 when the outbreak of the Korean War re-emphasized the need for small nuclear devices.

The Air Force made early plans to carry and deliver large and heavy hydrogen bombs and, in 1950, established two projects, Brass Ring and Caucasian. Brass Ring envisioned carriage of the weapon in an unmanned drone B-47, which would be guided to a target by a mother ship and destroyed in the detonation. This project was given considerable support, due to uncertainty concerning the possible yield of a hydrogen bomb, then estimated to lie between 10 and 40 megatons.

[redacted]

This possibility was discussed at a conclave of scientists and AEC representatives June 19, 1951, and it was concluded by the attendees that a practical thermonuclear weapon was achievable, using radiation energy as a compressing force.

Due to some personal differences of opinion, Teller proposed the creation of a new physics laboratory to develop thermonuclear devices. He was supported in this stand by the Air Force, which offered to provide a suitable laboratory. Subsequently, the

[redacted]

AEC established a laboratory at Livermore, California, under the administration of the University of California. The contributions of the University of California Radiation Laboratory to the early development of thermonuclear weapons were somewhat meager, except that the existence of the laboratory helped to encourage the over-all program.

[redacted]

The computational work involved in analyzing the thermonuclear process was a colossal task, and could not have been accomplished without the great advances in computing equipment that took place in the late 1940's and early 1950's. The IBM 601 was considered quite a machine in 1945, but it was far surpassed by the Maniac, designed at the Institute for Advanced Study, Princeton, New Jersey, and which became available in 1952. A problem that would require 3 months work by the 601 could be solved in 2 days by the Maniac. It is of record that, in the course of running a thermonuclear problem on the Princeton Maniac in 1953, the number of basic arithmetical computations performed was of the same order of magnitude as the total number of similar operations performed at Los Alamos (excluding those done on the Los Alamos Maniac) in the entire 10 years of operation of the Laboratory.

The first task assigned to the Los Alamos Maniac was to perform more exact and extensive calculations of the thermonuclear process. The theory of radiation implosion was refined and reinterpreted, and the flow of radiation pressure along channels between the fission and fusion components of the bomb was determined.

[redacted]

Sandia and Los Alamos forwarded a joint letter to the Division of Military Application May 22, 1952, proposing that the TX-14 be designed with the following guidelines:

[redacted]

1. Maximization of yield to the point where escape of a manned transporting bomber was impossible (the use of an unmanned drone had meanwhile been discarded), or production of the largest yield possible in the size allowed.

2. Diameter not to exceed 64 inches; length, about 20 feet; and weight, about 50,000 pounds. (This made the TX-14 comparable in length and weight to the World War II Block Buster bomb which was 27 feet long and weighed 44,000 pounds).

3. Bomb to be capable of withstanding forces involved in careful handling, aircraft loading and carrying, and free or retarded fall.

4. Bomb to have a capability for air-burst operation only.

[redacted] b(3 Do

The term "emergency capability" was defined to mean that there would be no factors that would prevent carriage of the TX-14 in manned aircraft. No "gold-plated" engineering would be done, operational suitability tests would not be conducted, information on reliability would be lacking, no inflight insertion device would be provided, and assembly and use would require the services of trained scientists and engineers. These TX-14 emergency-capability devices would thus be in a state corresponding to the Little Boy and Fat Man bombs at the time of their use in World War II.

Los Alamos was assigned overall responsibility for the TX-14, and Sandia would provide the ordnance engineering. [redacted] b(3 DOE

The Division of Military Application forwarded this proposal to the Military Liaison Committee, which replied, June 13, 1952, that the Joint Chiefs of Staff

had established a military requirement for the development of thermonuclear weapons with yields of 1 megaton and over, requesting that these weapons be compatible in size, shape and weight with delivery systems that would be available in 1954. Production facilities for thermonuclear materials would be developed immediately. It was felt that any prior production of a deliverable thermonuclear weapon by the Soviet Union would reduce the existing American lead in weaponry, and that such a shift in balance might well cause a change in Soviet policy. This factor alone provided adequate justification for an approach involving considerable technical risk and a large expenditure of funds.[11]

[redacted]

By November 1954, all emergency-capability units had been modernized to Mk 17/24 Mod 0 status. The design did not differ in any important aspects from the TX-17, but the components were of certified stockpile quality. The Mk 17/24 Mod 0 Bombs thus became the first thermonuclear weapons to be stockpiled as a result of a regular production program.

The weapon could be carried and dropped by a B-36, if the release was made at an altitude of 40,000 feet or higher. Lower altitude releases, into denser air, would produce high-shock loadings. The B-52 could not be used as a carrier due to its high speed, which also created high shock loadings at release.[78]

It was noted in the May 21, 1954 meeting of the TX-Theta Committee that heavy production rates had been authorized for Mk 17/24 Bombs in late 1954, and it was suggested that as many improvements as possible be incorporated prior to that date. [redacted] b(3) DoE

A Mk 7-type automatic inflight insertion mechanism was to be used, and this redesign required some lengthening of the bomb nose. Sandia ran a wind-tunnel check, which showed that little effect on weapon stability resulted. The Mod 0 of the Mk 17/24 was not exactly a model of aerodynamic stability, as it oscillated with an amplitude of about 10 degrees during its fall, even with parachute retardation, but the nose, which was 2 inches longer, did not aggravate this effect.

[redacted] b(3) DoE.

Additionally, the tail fin of the TX-15 was changed at this time from an all-metal design to one of composite metal and plastic, and this change was also made in the Mk 17/24 Mod 1.

[redacted] b(3) DoE

It was relatively simple to design contact fuzes for fission weapons, since these devices were covered with a light ballistic fairing that was able to sense the shock of impact and signal detonation before any real physical damage was done to the weapon. However, in thermonuclear devices, the heavy case would have to sense the impending shock and detonate just before actual impact took place.

Discussions with Los Alamos led to the conclusion that the secondary reaction would occur if the primary reaction was completed, and it was decided to use a barium titanate crystal contact fuzing system developed for fission bombs.[83] Sandia performed some sled tests in Area III, from which a design was evolved using two networks each containing two impact crystals, mounted on the nose of the bomb. A fast-firing gap-type X-unit was concurrently developed.

Further work on parachutes was necessary, in order to produce a design which would permit releases from B-52 bombers and result in a down-time of 75 seconds. Sandia placed an order on Wright Air Development Center for both standard and heavy-duty parachutes with diameters of 40 feet. The first phase of this testing program was completed January 19, 1955, after eight drops had been made with standard chutes. Test results showed that opening shocks were lower than expected. However, the requirement for carriage in the B-52 was canceled April 24, 1956, due to release troubles in which the suspension sling failed to retract properly. Subsequently, the Strategic Air Command decided to use a 64-foot-diameter chute and to place an operational restriction of 365 knots airspeed and 20,000-foot altitude on the weapon at release.

The Mk 17/24 Mod 2 Bomb was design-released June 1, 1955. The weapon contained a Mk 17 Mod 0 Fuze, with both contact- and air-burst capabilities. The bomb was 61.4 inches in diameter, 298 inches long, and weighed 42,000 pounds. [redacted] b(3) DoE

The weapon could be stored for 18 months under stockpile storage

[redacted]

conditions, and for 15 days as a ready weapon. Efforts were under way to increase the latter figure to 30 days, to meet the desired ilitary characteristics. A 6-month capability was desired for the fuze, normally stored in its own sealed container, and the attainment of this goal appeared hopeful.

Prior to dropping the weapon from the bomber, a safing switch was closed. Release of the weapon resulted in closure of the pullout switches, and weapon power was applied to the electrical system of the bomb. Parachute deployment was now initiated, if this option had been selected. At the selected arming altitude, an arming baro closed and started the charging of the X-unit. At the selected height for air-burst operation, the firing baro closed and detonated the bomb by firing the trigger circuit. The contact fuze acted as backup in the event of air-burst fuze failure, or it could be selected as the fuzing option. [redacted] b(3) DoE

[redacted]

About 25 percent of the Mk 17 stockpile was converted to the Mod 2 configuration. The work was performed at sites by the Military under Sandia supervision during the period June to August 1956. The program which would have resulted in the Mk 24 Mod 2 was canceled, and by October 1956 all Mk 24's had been retired in favor of the Mk 36 design.[22]

The Mk 17 Mod 1 weapons were retired between November 1956 and August 1957. The Mk 17 Mod 2's were retired between August and October 1957, since Mk 36 weapons were then entering the stockpile in large enough quantities to fully support military plans for weapons of this yield range. The Mk 36 provided a higher yield than the Mk 17 and at a much lesser weight.

TRACING THE ORIGINS OF THE W76: 1966–SPRING 1973

by

Betty L. Perkins

ABSTRACT (SRD)

The objective in writing this report was to place the development of the W76, before it entered Phase 3, in a historical perspective. The author has rather arbitrarily chosen to consider for this pre-Phase 3 history, the history of the weapon program at Los Alamos during the years 1966–May 1973.

The report tries to provide some understanding as to why, in the spring of 1973, the Los Alamos Scientific Laboratory received the Phase 3 assignment and why the assignment was important to the future of Los Alamos. In addition, the report provides insight into why historically the design of the W76 evolved as it did.

Chapter I provides general information including the organization of the Laboratory during the time-period of interest and the definition of what is included in the different phases in weapon development.

Chapter II discusses the work on primary design.

(b)(3)

(b)(3)

Chapter IV briefly describes the early development effort for several of the materials that would be important in the W76 program.

(b)(3) The engineering status of several ancillary components such as detonators and gas storage systems is reported. Chapter IV notes the vulnerability tests relevant to the early LASL XW76 weapon program.

Chapter V includes a brief discussion of the history of the weapon systems assigned to Los Alamos as Phase 3 programs during the 1966–spring 1973 period. The extensive effort that was required for the various Phase 1 and 2 programs and the early advanced development programs under consideration during these years is also discussed. It is noted that despite this effort, the Los Alamos weapon teams failed during 1966–1972 to win a viable Phase 3 assignment to develop a warhead for a strategic missile weapon system. The chapter also includes some trends in the U.S. nuclear stockpile that are important in understanding the 1970–1980s weapon programs.

Chapter VI outlines the Los Alamos effort for the Mk 18 and the later Mk 400 programs; programs that served as the precursor programs to the W76. This chapter provides insight on the Los Alamos effort to obtain a Phase 3 assignment for a strategic warhead and the success in this effort that resulted in the long desired award of the XW76 program to Los Alamos.

CHAPTER I. INTRODUCTION

A. Explanation

1. Assignment

The assignment given to the author was to outline the history of the development of the W76 warhead (presently carried on both the Navy's Trident C4 and D5 submarine-launched ballistic missiles). Because the Los Alamos Scientific Laboratory [LASL] received the Phase 3 assignment for this warhead in the spring of 1973, it would be reasonable to assume that a history of the W76 would cover only the period from the Phase 3 assignment until the initial operational capability of the W76 was achieved in October 1979 (Poseidon back-fit). But history is continuous. What happens at one point in time is dependent upon what happened earlier.

In order to set the development of the W76 in the necessary perspective, give some understanding as to why in the spring of 1973 LASL received the Phase 3 assignment and why the assignment was important to the future of Los Alamos, and indicate several reasons why the design of this device evolved as it did, a history of work prior to 1973 is required. The author has rather arbitrarily chosen to consider for this history, the history of the weapons program at Los Alamos during the years 1966–May 1973. (However, to give continuity, some aspects of the program are also described for work completed before 1966.) This pre-Phase 3 effort at Los Alamos is the focus of this report.

However, the author must insert a warning to the reader. It must be noted that to further increase the complexity that is history, it is almost impossible to identify all the factors that go into determining actions during a specific era. In addition, the description of an event is dependent upon the available "data set" of historical documents. Moreover, how an event is described in a point in time is dependent on what happens later and on our own personal experiences, knowledge, and "mindset." Thus, no history can be completely objective.

2. Overview

Before the award of the design effort for the W76 to Los Alamos, the U.S. nuclear weapon designers had been required—by the introduction of MIRVed (Multiple Independently Targeted Reentry Vehicle) missiles into the U.S. weapon arsenal—to develop lightweight/small warheads for use in the missiles' reentry vehicles.

(b)(3)

(b)(3)

Chapter IV will briefly describe the early development effort for several of the materials that would be important in the W76 program.

(b)(3)

The engineering status of several ancillary components such as detonators and gas supply systems will be reported. Chapter IV will also note the vulnerability tests relevant to the LASL XW76 weapon program.

Chapter V will outline and briefly discuss the history of the weapon systems assigned to Los Alamos as Phase 3 programs during the 1966–1972 period. In addition, mention will be made of Phase 1 and 2 programs and early development programs under consideration during those years. This chapter will attempt to inform the reader as to the extensive effort that was required. However, as Chapter V will also describe, the Los Alamos weapon teams failed during 1966-1972 to win a viable Phase 3 assignment to develop a warhead for a strategic missile weapon system. The W62 for the Minuteman III with a Phase 3 of 1964 went to Livermore. The W68 for the Navy's Poseidon submarine with a Phase 3 of 1966 also went to Livermore. Earlier, the W56 (the warhead for the Minuteman I, II) and the W58 (the warhead for the Navy's Polaris) had also gone to Livermore. The Chapter will also note some trends in the U.S. nuclear stockpile that were important for the weapon programs at the Livermore, Sandia, and Los Alamos laboratories.

Although the program was finally canceled, of particular importance to the later W76 development was the Mk 18 program. This program will be covered in some detail in Chapter VI. The Navy's Mk 400 program was the precursor program to the W76. The history of *the Mk 400 program will also be outlined in Chapter VI. This chapter will discuss the vital* question: who would win the Phase 3 for the Mk 400 (XW76) Los Alamos or Livermore?

B. Los Alamos Scientific Laboratory Management Structure and Philosophy

1. Norris Bradbury

Norris Bradbury served as the director of the Laboratory at Los Alamos from October 1945 until September 1970. When he accepted this job and became director in October 1945 just after the end of WWII, he promised that he would serve for six months. But the six months of service stretched into twenty-five years.

In a January 1967 letter to Charles Winter, Deputy Director of the Division of Military Application, Bradbury described the Laboratory, "Los Alamos is organized on a facility and technology basis; LRL is organized more on a project basis." Bradbury also noted, "Internally in the Laboratory, the weapon program is steered by a committee chaired by the Laboratory Director and comprised of Assistant Directors and relevant Division Leaders. Basic decisions are made by this group, the members of which carry the authority within their respective areas of responsibility to implement them. More detailed discussions and decisions within the framework

made by the Defense Department. It we weren't providing the technology that allows these high yields in smaller packages to be made we wouldn't be keeping up with the Soviets because the number of Minuteman we have is the same and the number of submarines is the same. It is the warhead technology that enables this country to keep up its deterrent, and that is only because of the technological base which the weapons laboratories supported by the Committee and the Commission provide the country."[4]

As part of his new job as director at Los Alamos, Agnew would continue and intensify his campaign for Los Alamos to receive the Phase 3 assignment for the W76. He was successful in this effort.

C. Weapon Group Designations/Responsibilities, Support and Basic Research Groups, and Committee Functions

As noted in the organization charts of Figures I-1 and I-2, the work at Los Alamos took place along the lines of various disciplines. A set of Divisions, each concerned with a particular interest was set up. In each Division there were groups where the work was again more narrowly specified. However, to produce a specific weapon, members from all the different divisions came together as needed. The following sections will attempt to explain how the Laboratory functioned in terms of organization.

1. Weapon Groups: 1966–September 1972

a. Weapon Design

Very early in the history of the various groups in the Laboratory (1948–December 1970), W-4 was designated as the small weapons theoretical design group responsible for the design of single-stage devices and primaries. However, in January 1971, a division known as TD-Division, responsible for the theoretical design of nuclear weapons, was created. Group members in W-4 then became group members in what was designated TD-4.

Until the formation of TD- and C-Divisions, members of T-Division were responsible for computing, code development, theoretical problems in mathematics, and some aspects of weapon design. For a number of years, until 1973, Carson Mark was the Division Leader. Another important member of the division office at that time was secondary designer Robert Thorn. Until Thorn became TD division leader in 1971, he also headed T-2. (A "new" T-2 group called the Nuclear Data group was then formed in April 1971.) Formed in September 1959, T-3 was the hydrodynamics group. Until it became TD-1 in January 1971, T-4 (which had become a group in May 1970) was also a weapons group in T-Division. (Beginning in October 1971, the "new" T-4 became the group concerned with equation of state and opacity.) The group T-5 members were concerned with numerical analysis; in January 1971, this group became TD-5. From July 1963 until January 1971, T-6 was the fission weapons design group. [Author's note: This group under Dave Woods was apparently a backup design group for the other design groups. By having multigroups, it was possible to see if the design teams agreed.] Group T-7 was the computer research and development group. In April 1968, its members joined C-Division. Members of T-8 were concerned with applied mathematics (mathematical methods). Their well-known group

[4]"Remarks by H. M. Agnew Concerning Need for Testing," (June 15, 1970 Briefing), DIR-2244 (SRD) (October 9, 1970), pp. 7.6–7.7, A99-019, 269-1.

leader was Stanislaw Ulam. In the January 1971 reorganization, members of this group were split into TD-5 and TD-6. The weapon effects group was T-12—until the group was dissolved in July 1968. Once TD-Division and C-Division were formed, the interests of members of T-Division were those required to provide theoretical and analytical support to most of the major programs of the Laboratory.

C-Division was formed in April 1968 from parts of T-Division and Data Processing. This division was called the Computing Sciences and Services Division. Thus the name indicated the type of work for which the division member's were responsible. Nicholas Metropolis served as an advisor from April 1968 to March 1974. In 1972, the members of C-Division were responsible for maintaining and operating one IBM 7094, two CDC 7600s, three CDC 6600s, two IBM 1401s, and one IBM 1360. In addition, the members' interests included research in statistical theory and development of methodology, consultation, assistance in numerical procedures and techniques for problem solving, numerical analysis, and applied mathematics and programming.

On January 1, 1971, a new division was formed that included the "old" T-2, T-4, T-5, T-8, and W-4 groups. This division was called TD, or the Division of Theoretical Design. Members of the division office included several members of the Los Alamos weapon design team. Robert Thorn was the division leader with Harry Hoyt the alternate division leader. TD-1 was called the Thermonuclear Weapons Physics group. TD-2 was the Thermonuclear Weapons Design group. It was this group that was chiefly concerned with the design of secondaries. TD-3 was Weapons Outputs. Another very important group was TD-4, Small Weapons Design. This group was responsible for the design of single-stage weapons and the primary in multistage weapons. TD-5 was called Codes Development. TD-6 was the Monte Carlo group. Concerning TD activities as of June 1972, it has been reported, "This Division is responsible for the theoretical design of nuclear weapons. The Division is responsible for work on the physical principles of nuclear weaponry, research and development on new concepts, and output effectiveness studies of various classes of weapons. An important portion of the effort is directed toward design and interpretation of nuclear weapon tests. ...The personnel of the Division perform calculations based on fundamental theory but use as a database experimental data from other groups of the Laboratory."

Most of the work in T, C, and TD took place in the main technical area, called TA-3.

b. HE Production and Development and In-House Field Tests

A division called GMX was formed in 1948. This division, divided into a large number of groups, was responsible for explosives and "their interaction with metal." Duncan MacDougall was division leader from August 1948 until September 1970 when MacDougall became Assistant Director for Weapons. [Author's note: It should also be noted that another strong figure in the early weapon program was Max F. Roy. He served in the director's office as Assistant Director for Production from August 1948 until his retirement in June 1970. There is a story that circulates in the laboratory that Max Roy wanted to contract work out, but MacDougall wanted the work done in-house.] Eugene H. Eyster served as alternate GMX division leader between 1954 and 1970 when at that time he became division leader.

GMX-1 was the nondestructive testing group. As will be noted, this group became, in September 1972, M-1. Their main work site was TA-8 (Technical Area 8). This site is known as

(b)(3)

(b)(3)

The history of the early Livermore design program is the subject of LA-13755-H (SRD), and for more information the reader is referred to this document.

(b)(3)

The Bradbury memo was followed by the establishment of the Small Systems Group. During their first meeting on August 29, 1957, the group members decided that a delegation from Los Alamos should visit Livermore in September.

(b)(3)

(b)(3)

a. Military Requirements for Small, Lightweight Warheads

As noted previously, in the mid-1960s the Los Alamos design group had begun work on 10-inch diameter or less primaries.

(b)(3)

The reason for this great interest on the part of the design laboratories in the 10-inch and less diameter was the fact that the Military was pushing for small, lightweight systems. By this period, the missile/guidance/nose-cone establishment in the United States had developed their systems to where it appeared that it would be possible to put several warheads on one intercontinental ballistic missile (ICBM), deploy the missile, and have each of the warheads hit a different target. This concept is referred to as use of multiple independent reentry vehicles (MIRV). It was felt at that time that the USSR was also going into these types of systems. Because a warhead is much less costly than a missile, the Military wanted to pack as many warheads as possible into each missile. This desire for as many warheads as possible on one missile pushed the nuclear weapon groups to achieve as small as possible in terms of diameter. Moreover, the Military wanted as long a range as possible for each missile; this requirement pushed the weapon groups to try and design minimum-weight warheads.

A request for multiple-carriage capability for the forthcoming improved Minuteman system was formalized in a January 1963 revision to the Phase 1 study. Three reentry vehicles were to be carried in this system—designated the Mk 12 (L). On February 12, 1964, Phase 3 authorization was given for the Mk 12 (L). Livermore and Sandia Corporation, Livermore, were to receive the assignment (the warhead would carry the designation XW62). In November 1964, the Military Characteristics were amended to provide a warhead "compatible with a MIRV application on the advanced Minuteman missile system."[95]

(b)(3)

On August 31, 1964, in a letter to AEC Chairman, Glenn Seaborg, Harold Brown, Director of Defense Research and Engineering, formally proposed the lightweight warhead program. Later, a paper titled "MIRV on Minuteman

[95]Betty L. Perkins, "Tracing the Origins of the Modern Primary: 1952-1970 (U)," Los Alamos National Laboratory report LA-13755-H (SRD) (April 2, 2001), pp. XII-7–XII-14.

and Titan II" and dated March 3, 1965, was provided to the administrations at the weapon-design laboratories.

(b)(3)

(b)(3)

1. Loss of the Poseidon C-3 Warhead to Livermore

In March 1965, a paper titled "USN Missile Force Improvement Summary" was published under the sponsorship of the Institute for Defense Analyses. This paper suggested a design for a small reentry vehicle designated the Mk 100 and reported that eight of the Mark 100s could be included in the Navy's Polaris A-3 system.[107]

By April 1965, the Navy decision makers had decided on a new missile to be known as Poseidon. Compared to the Polaris A-3, the Poseidon was to be longer and have a larger diameter, carry a heavier payload, and achieve a greater range. Each missile would carry multiwarheads and would use a space bus to carry and distribute the warheads on target.[108]

A December 6, 1965, letter from the Chief of Naval Operations requested AEC participation in the Poseidon conceptual studies. On the cover sheet of this letter, there is a note written by a person in the Los Alamos management to the effect that Los Alamos had requested that the Navy invite Los Alamos to compete on the Poseidon assignment. The note stated, "...we [LASL] should really go after the business."[109]

On January 13, 1966, Director of Defense Research and Engineering, John S. Foster, Jr., in a letter to AEC Chairman Glenn T. Seaborg indicated that the Navy was favoring the Mk 100-type, small-reentry vehicle with its multiwarheads for use on the new Poseidon C-3 fleet ballistic missile.[110]

Representing the various groups at Los Alamos, on April 28–29, 1966, Peaslee, Aragon, Horpedahl, and Hoverson attended a meeting in Washington on the Poseidon C-3 missile system.

(b)(3)

[110]John S. Foster, Jr. to Honorable Glenn T. Seaborg (SRD) (January 13, 1966), 2 pp., A99-019, 217-15.

(b)(3)

In May 1966, the AEC published a Phase 2 feasibility study for a warhead for the Poseidon C-3 missile system. Proposals from the Los Alamos Laboratory were included in this study.

(b)(3)

Although the Los Alamos group very much wanted the assignment of the Navy's warhead (to be known as the W68), such was not to be the case.

(b)(3)

Bradbury wrote a letter dated June 1, 1966, to Livermore director Michael M. May.

(b)(3)

Bradbury proposed a "pie split"—Livermore would take the Mk 3 Poseidon warhead and Los Alamos would take the warhead for the Mk 18.[113]

(b)(3)

(b)(3)

This decision must have been reinforced after hearing from the Peaslee delegation, when they returned from Washington, as to how badly Los Alamos had come off in the bid for the W68.

(b)(3)

On April 4–5, 1966, a group from Los Alamos composed of William Deal, E. L. Peterson, D. M. Mosher, and Gene Eyster from GMX Division and Bill Davis from W-1 visited Livermore.

(b)(3)

[113]N. E. Bradbury to Dr. Michael M. May (SRD) (June 1, 1966), 2 pp., A99-019, 186-2.

(b)(3)

(b)(3)

1. Initial Considerations

(b)(3)

The Hydrodynamic Committee was assigned the job of naming the proposed primary.[144]

(b)(3)

2. Class Name

Towards the end of November 1967, the problem of what primary to use in the Mk 18 was somewhat resolved.

(b)(3)

[144]Jane H. Hall to Distribution, Subject: "Memorandum of Understanding – WLPC No. 21," AD-1814 (SRD) (November 13, 1967), p. 1, A99-019, 91-10.

(b)(3)

(b)(3)

This means that every detail will have to be worked out in order to design local tests, attachments, etc. He has requested help from Sandia Corporation in this work."

(b)(3)

For example, at the WWG meeting of February 21, 1968, it was reported that LASL had been assigned development responsibilities for the Mk 18. Bradbury commented that LASL had better pursue all versions of the Mk 18. During the meeting various possibilities for the warhead's design were discussed by Peaslee.

(b)(3)

a. Design Program

(b)(3)

During the WWG meeting of March 13, 1968, Osborne explained his work up to that point.

(b)(3)

(b)(3)

Diagnostics were to be alpha, time interval, radiochemistry, and on the secondary (1) Pinex

(b)(3)

(originally an acronym for Pinhole Neutron Experiment)—using the television time integrated method; (2) TRAX (Time Resolved Asymmetry Experiment)—time and space resolved measurement of 14-MeV neutron production in the boost region; and (3) RTA (Radiation Time of Arrival)—radiation time of arrival where observation was made of x-rays through a transparent hole in the case. It was noted that the rack design was very complicated and that the design and fabrication schedule was tight.

(b)(3)

1. Livermore: A Small, Lightweight Secondary

(b)(3)

In the mid-1950s the U.S. Military began to push for smaller, lighter nuclear weapon designs. At Livermore, the secondary design team began work on the design of a secondary suitable for this application.

(b)(3)

This type of lightweight device was the design objective of a UK/U.S. study group called JOWOG-3 (Joint Working Group 3).

(b)(3)

R. Thorn discussed this design concept at the July 16, 1959, meeting of the TWG.[5]

The design was again discussed by R. Pollock during the August 20, 1959, TWG meeting. By now the design was more complete.

(b)(3)

2. Early Mk 18 Program

a. Options for a Warhead for the Minuteman III Missile

In the mid-1960s the Military began to consider a possible Minuteman III missile that would employ a multiple warhead carriage. The warhead for this application was designated Mk 18.

(b)(3)

In a June 1, 1966, memo, Bradbury proposed to do a "pie split" with Livermore. If Livermore would support Los Alamos receiving the Mk 18 assignment, Los Alamos would not oppose the assignment of the Mk 3, the Poseidon warhead, to Livermore.[35]

In a TWX dated June 23, 1966, AEC Director of Military Application, Delmar Crowson, informed the Laboratories that in order to have different nuclear design approaches for the Mk 3 and Mk 18, he was going to assign the Mk 3 to Livermore and the Mk 18 to Los Alamos.[36]

(b)(3)

Newtonian telescope; a beam splitter formed images for two television cameras. Proximity focus image intensifiers excluded gamma-produced light before neutron arrival and debris-produced light thereafter. The instrument package was protected by kinking the path from the device as much as possible and placing baffles along the optical path pipe to prevent neutrons and gamma rays from reaching the television package."[97] The TV Pinex technique had first been used by the Los Alamos group on the Rickey test fired in 1968. TRAX was a time-resolved asymmetry type experiment. In this type of diagnostic an array of detectors viewed the boost region through collimators to give both a time and energy resolved measurement of the 14-MeV neutron production in the boost region. This technique was first used on Door Mist in 1967.[98]

Vander Maat discussed his calculations vs the then available diagnostic data during the January 28, 1970, meeting of the TWG. If he used one type of input in his secondary calculations, he obtained a number similar to the fission but not the fuel yield; if he used a different input, he obtained a number similar to the fuel but not the fission yield. Thus, no matter what his input parameters were, he could not get an output consistent with the observed data. The meeting minutes state his conclusions, "The fuel results indicate that either we do not know how to calculate fusion and fission or we do not know how to interpret the radiochemical results."[104] This problem, as will be noted in the following paragraphs, would continue to bother ~~the design team.~~

(b)(3)

(b)(3)

d. Results and Implications

(b)(3)

Good data had been obtained from zero time until 4 μs when a short noise pattern had occurred. The data were again good from 4 to 8 μs after

(b)(3)

which time no further data were collected. Additional information and pictures of the Pinex images are available in the cited reference.[237]]

To conclude the data presentation at the April 18 WWG meeting, radiochemist Bryant reported the radchem results,

(b)(3)

[237]Leslie M. Redman, "LASL Weapons Quarterly (U), for the Period Ending March 31, 1973," Los Alamos Scientific Laboratory report LA-5330-PR (SRD) (June 1973), pp. 60–62.

(b)(3)

h. Results

(b)(3)

Preliminary results were again discussed during the August 15, 1973, WWG meeting. These included a presentation by Kruse of the J-14 data. The TRAX experiment had yielded gamma and neutron signals with good time resolution. Kruse presented graphs showing detector currents for gammas and neutrons. Berzins reported on the J-12 Pinex results. He included a computer analysis of the Pinex data.

(b)(3)

(b)(3)

As discussed in Chapter II, the postshot report on the primary was released on March 14, 1974.

3. Reservoir Designs to Provide Minimum Helium in the Boost Gas

In a March 1969 memo, primary designer R. Canada outlined the problems that were the result of the formation of ^{3}He from the decay of the tritium used in the primary's boost gas.

(b)(3)

The yield of a boosted primary is degraded as tritium is converted to ^{3}He both by the loss of the source of 14-MeV neutrons and also by the decrease of the pre-boost multiplication rate caused by the high cross-section for neutron capture which is characteristic of ^{3}He." He went on to add, "In a conventional boosted single-stage device the tritium produced by ^{3}He appears too late in the bomb's explosion to contribute to the yield, and the temperature does not get high enough to produce significant $^{3}He + D$ fusion."[293]

(b)(3)

C. Vulnerability

1. Considerations

As the USSR began to develop missiles that carried nuclear weapons, military planners in the United States became concerned that these types of weapons could be used as defense weapons against incoming nuclear-armed missiles from the United States. The question then arose as to how to "harden" the U.S. reentry vehicles and warheads to minimize the impact of this type of Soviet defense.

In addition, it became technically possible in the United States to have one missile carry more than one warhead. As these warheads were released and detonated over a target(s), and if the offensive warheads were detonated too close together during a similar time period, the radiation released from one would affect the others. Again, there was the question of how best to deploy these types of warheads and how to "harden" each warhead from the effects of the others (fratricide).

In response to these problems, scientists in the U.S. weapon complex developed special materials and engineering features designed to minimize the damage (both from radiation and from the shock and heat produced by the interaction of radiation with materials) to a nuclear warhead

(b)(3)

~~It was necessary to test~~ these designs and materials to see if they met the design objectives. The tests included field-type tests and tests at NTS. In addition, computer codes were developed, based on experimental data, to predict the behavior of components under adverse conditions.

Several types of field tests were employed. In one type of test, shocks were sent into the special materials to study their behavior. Other tests measured the effects of high temperature and similar adverse environments. In another type of test, radiation from a radioactive source, an accelerator, critical assembly, or reactor was used to expose the device to neutrons or x-rays. The type and amount of radiation that could be delivered was dependent upon the irradiating source. These field tests were never able to duplicate an actual exposure environment during deployment.

(b)(3)

The most complex and expensive tests employed were the NTS-type tests. These tests were used to mock-up, in so far as possible, the actual conditions that a warhead might be subjected to. In the following section these vulnerability tests will be briefly described in terms of the specific tests that were relevant to the pre-Phase 3 development of the XW76.

2. NTS Vulnerability Tests

a. Description

NTS vulnerability tests were "effects" tests where the output (neutrons/x-rays) from a detonated nuclear device was used to determine how various weapons, weapon materials, and engineering features would respond should they encounter a hostile environment. This environment might result from the nearby detonation of a nuclear ABM sent by the targeted country or from close detonation of warheads from a U.S. missile in a MIRVed type of deployment. The hostile environment might be encountered at high altitude or near the target.

In this type of NTS test, the sponsoring agency specified what type and level of radiation was required for their experiments. Participating agencies could also specify what exposure would be most useful in their experiments.

Many of the vulnerability tests were sponsored by the Department of Defense/Defense Atomic Support Agency (DOD/DASA). These tests usually had, as noted in Chapter I, double names. Some were sponsored by a weapon laboratory. The sponsoring agency's project managers decided (based on what they wanted in terms of radiation output) on a suitable device. The laboratory (Los Alamos or Livermore) that had designed this device was then asked to provide the device and to assume responsibility for emplacement and detonation of the device. In general, this device was usually a design that had already undergone a previous test(s) where the output radiation had already been determined. If a tested device were not available, a preliminary test to determine specific output might take place at NTS. In addition to supplying and detonating the device, the scientists at the specified laboratory were also responsible for the device diagnostics. In addition, certain diagnostics, for example seismic yield, were done on a routine basis by outside agencies.

Once the nuclear device with its known output had been specified, suitable stations at various distances from the device were set up in the facility in which the experiment was to take place. (Because of the layout required, vulnerability tests were usually done in tunnels at NTS.) The necessary shielding was installed. Instruments to measure the flux of the radiation falling on the samples to be tested were designed, built, and installed. The pieces of equipment or samples for which exposure data were desired were inserted at the specified locations. Special closure assemblies, used to close off the affected region and in theory, prevent bomb debris from spreading into the main tunnel/environment, were designed and installed.

The test configuration with its tunnels, test stations, access holes, and other required facilities could be extremely complex.

(b)(3) The zero room housed the detonated device, firing stand, firing and diagnostics equipment, and front-end closures.

(b)(3) Another line of slight extended from the zero room into an alcove designated "M." The line of sight for the major experimental areas was constructed in a main

drift 925 ft in length. A further 30-foot extension consisting of an arched tunnel housed alcove L. As shown in Figure IV-4, several shafts were used to access the various areas.[333]

John Hopkins, former Test-Division leader, has commented that each layout for a vulnerability test was different. However, all were major efforts in terms of construction and instrumentation.

(b)(3)

CHAPTER V. WEAPON PROGRAMS AND CHANGES IN THE STOCKPILE: 1965–MAY 1973

A. Phase 3 Programs at Los Alamos

1. Assignments

a. Phase 3 Programs Entering the Stockpile

During the period 1965–May 1973, the Los Alamos Scientific Laboratory weapon development and design group members were responsible for several Phase 3 weapon programs. [The Phase sequence for weapon programs is noted in Chapter I.] For those weapons that entered the stockpile, the specific weapon program, the date of the Phase 3 award, and the date of the attainment of Phase 6 are as follows:[1]

Weapon Program	Phase 3	Phase 6
B61 Mod 0	June 1963	January 1967
B61 Mod 1		February 1969
B61 Mod 2	August 1971	June 1975
B61 Mod 3	March 1972	October 1979
*W66**	*January 1968*	*October 1974*
W69	January 1967	February 1972
W72	May 1969	September 1970
* Never deployed to the field[2]		

b. Canceled Phase 3 Assignments

In addition to those weapon programs assigned to Los Alamos that were in or went into Phase 3 during the 1965 to 1973 period and entered the stockpile, several Phase 3 programs were assigned to Los Alamos but were later canceled. These were the XW64, XW67, XW73, and XW74.[3]

c. Discussion

The Phase 3 weapon programs under development at Los Alamos from 1965 through May 1973 will be discussed in the following sections. Each section will cover a specific weapon.

---

[1]"FY 1994 Annual Weapons Program Report," DOE Albuquerque Operations Office report (SRD) (October 1, 1994), pp. 25–26, 301, 309, 326.

[2]"FY 1994 Annual Weapons Program Report," DOE Albuquerque Operations Office report (SRD) (October 1, 1994), p. 301.

[3]Betty L. Perkins, "Why Nougat? (U)," Los Alamos National Laboratory report LA-12950-H (SRD) (November 1, 1995), p. A-3.

2. Weapon Programs

a. B61

While the Phase 3 assignment for the B61 Mod 0 was received by the Los Alamos Scientific Laboratory in 1963, the Los Alamos weapon groups were going to find that they would have an extended development program for this weapon. The B61 would go through many models and deployment objectives over a period of many years. Several Mods of this bomb, in modified designs from the ones that were first developed, are still in the U.S. nuclear weapon stockpile.

(b)(3)

The B61 Mod 0, 2, and 5 bombs would be carried by U.S. Navy A-6E and F/A-18A/C/D aircraft. These bombs would also be carried by U.S. Air Force F-16 A/B/C/D and F-111 D/E/F aircraft. The later Mod 3, 4, and 10 variations would be carried by U.S. Air Force F-16 A/B/C/D and F-111 D/E/F aircraft as well as F117-A aircraft. The Mod 3, 4, and 10 bombs would also be carried on NATO F-16 A/B aircraft and on Tornado aircraft. A recent version (Mod 7) is carried on the Air Force B-2A and B52-H. As the different Mods were introduced into the stockpile, many additional safety features would be included. The early Mod 0-Mod 2 designs discussed in this section have been retired from the stockpile or converted.[4]

(b)(3)

The B61 Mod 0 and Mod 1 weighed 715 lb and had a diameter of 13.3 inches and a length of 141.6 inches. The B61 Mod 0 first entered the stockpile in January 1967.

(b)(3)

[4]"FY 1994 Annual Weapons Program Report," DOE Albuquerque Operations Office report (SRD) (October 1, 1994), pp. 25, 29.

b. XW64

In May 1964, the Military Characteristics for nuclear warheads for the Lance Missile system were issued. This missile was to be a surface-to-surface missile for use by the Army. Both Los Alamos and Livermore submitted proposals for this warhead. As it would turn out, both Laboratories would initially receive the authorization to proceed. The XW64 was the nomenclature given to the Los Alamos design; XW63 was the nomenclature given to the Livermore design.

Los Alamos received the authorization to proceed with the development of the XW64 on July 20, 1964. (b)(3)

However, the initial authorization was soon withdrawn. Attempts were made by the Los Alamos management in 1966 to have the program reactivated.[77] But neither the XW63 nor the XW64 was ever produced.

The final warhead, that provided a nuclear capability for the Army's surface-launched guided missile (MGM-52C) known as Lance, was the W70. The Phase 3 assignment for the W70 warhead was given to Livermore in April 1969

(b)(3)

c. W66

The W66 was a two-stage thermonuclear warhead designed for use on the Sprint missile. This missile was a short-range, low-altitude, quick reaction intercept missile. Therefore, the missile had high launching and maneuvering accelerations and a very short reaction time between launching and the firing of the warhead.

(b)(3)

The Sprint missile/warhead was part of the Safeguard weapon system.

The AEC laboratories originally received the Phase 3 authorization for the development of the warhead for the Sprint missile system in September 1965.

(b)(3)

[77]N. E. Bradbury, Los Alamos Scientific Lab., Los Alamos, N.M. to Brig. Gen. Delmar L. Crowson, DMA, USAEC, Wash., D. C., DIR-2017 (CRD) (February 14, 1966), p. 1. A99-019. 217-7.

(b)(3)

(b)(3)

However, these tests were very useful in guiding the design of the XW74.[427]

(b)(3)

[429]R. K. Osborne and M. T. Thieme, "Theoretical Design of Implosion Weapons, 1959-1980 (U)," *Defense Research Review*. UCRL 53880-4-2 (SRD) (July 1992). p. 72.

(b)(3)

The fourth quarter report from W-Division for 1970 notes that the Poseidon C3 Alternate Front End Study had been completed by Lockheed Missiles and Space Company. The purpose of the study had been to identify the preferred design for a new reentry body payload, called the *Mk 1 Prime, for the Poseidon missile in the event that the Mk 3 MIRV system could not be deployed as planned.*

(b)(3)

The total warhead weight was 680 lb.[446]

Improved Spartan

(b)(3)

Phase 6 for the W71 would not be achieved until October 1974. (The weapon would be placed in the inactive stockpile in October 1976.[447])

In a February 24, 1970, letter to Chairman of the AEC, Glenn T. Seaborg, John S. Foster, Director of Defense Research and Engineering wrote, "The Department of Defense desires to determine the feasibility of a nuclear warhead for the Improved SPARTAN missile warhead section....The Improved SPARTAN missile is a sub-system of the SAFEGUARD ballistic missile defense system and is being designed to provide a long-range intercept capability in the exoatmosphere against ICBM and SLBM reentry vehicles (RVs), long-range intercept capability in the atmosphere against depressed trajectory RVs, a capability to intercept penetration-aided RVs, an endo- and exoatmospheric intercept capability against FOBS [Fractional Orbital Bombardment System], and an intercept capability against satellites (but only within missile performance limitations)." [Author's note: Wow, what an assignment!] Foster noted that the presently planned improved Spartan missile would use the Spartan missile's first and second stages while incorporating a new third stage(

(b)(3)

An effort through Phase 2 was requested for this improved Spartan missile.[448]

(b)(3)

The Laboratory's quarterly report for January–March 1970 states, "Though there are many system parameters as yet unresolved, the AEC has received a formal request to participate in the Phase 2 Feasibility study of warhead designs for the Modified Spartan missile system."

(b)(3)

[446]"Program Status Weapons Research and Development, October-December 1970 (U)," Los Alamos Scientific Laboratory report LA-4614-MS (SRD) (February 1971), p. 42. "W-Division Quarterly Status Report, October 1, 1970 through December 31, 1970," W-2301 (SRD) (January 15, 1971), p. 66, A86-016, 242-15.

[447]"FY 1994 Annual Weapons Program Report," DOE Operation Office report (SRD) (October 1, 1994), pp. 318–322.

[448]John S. Foster, Jr. to Honorable Glenn T. Seaborg (SRD) (February 24, 1970), 5 pp., A99-019, 186-10.

A TWX dated September 15, 1970, pointed out that the system cost for the Minuteman III and MIRV was 2.2 billion. The projected cost for the Mk 19 was approximately 130 million. Thus. the R&D cost for the Mk 19 was 5% of the total system costs.[467]

(b)(3)

FUFO

During 1970, the DOD guidance placed emphasis upon a new FUFO bomb

(b)(3)

SABMIS

There also continued to be an interest in a Sea-Based Anti-Ballistic Missile Intercept System. It was reported that development schedules for this system were such that tests of the warheads themselves would not be scheduled for FY 1971.

(b)(3)

[467]D. W. Bergen, Los Alamos Scientific Laboratory, Los Alamos, N.M. to C. I. Hudson, University of California, Lawrence Radiation Laboratory (SRD) (September 15, 1970), p. 3, A99-019, 188-4.

(b)(3)

(b)(3)

/It is a step in

~~the development~~ of a warhead for the Modified SPARTAN."[493]

Hardsite Defense (SPRINT II)

The third quarter report for 1971 from the Laboratory notes that a new component of the Safeguard ABM system, called "Hardsite Defense" (HSD), was to be implemented. It was reported, "HSD consists of an autonomous module for close-in, low-altitude intercept (≈10,000 to 30,000 ft) and is based upon three radar/data-processor units located about 10 nautical miles apart. The module will have six or seven firing sites containing about 100 modified Sprint interceptors to defend approximately 21 silos." The new interceptor was to be known as Sprint II; the planned readiness date was July 1977.

(b)(3)

/An AEC/DOD Joint Working Group had been set up to provide an alternative that used less tritium. A number of proposals had been suggested,

(b)(3)

[493]D. P. MacDougall to Major General E. B. Giller, USAF, ADW-158 (SRD) (November 5, 1971), p. 4, A99-019, 258-28.

(b)(3)

(b)(3)

High-Yield Warheads

Harold Agnew in a letter to Assistant General Manager for Military Application, Major General Edward B. Giller, stated that the country should consider what would happen if there were to be a ban on the use of MIRV and at the same time there was a ban on testing. Agnew recommended that the country should develop and test the highest possible yield warhead that could be carried as a single [warhead] on the Poseidon. He felt that the same should be done for the Minuteman and, if the Titan were kept in service, a high-yield warhead should also be developed for this application. He noted, "...we won't be carrying out our responsibility to the U.S. if we don't do these nuclear developments."[510]

(b)(3)

[510]H. M. Agnew to Major General Edward B. Giller, DIR-2250 (SRD) (July 6, 1971), 2 pp., A99-019, 269-3.

(b)(3)

(b)(3)

High-Yield Bomb (HYB), Formerly FUFO

In a February 28, 1972, memo, D. P. MacDougall reported that Giller in a January 20, 1972, document had indicated that he anticipated that a Phase 3 request might be initiated in the FY 1972–1974 time period for a High-Yield Bomb (HYB) (formerly FUFO).[543]

The second quarter report from the Laboratory for 1972 includes, as part of the High-Yield Bomb program, what was to become a very important project for the Laboratory. The report states, "The explosive TATB (1,3,5-triamino-2,4,6-trinitrobenzene) was first described in 1888, but was recognized as a very interesting heat-resistant explosive only in the 1950s. At that time the Naval Ordnance Laboratory reported briefly on its properties and presented a reasonable synthesis." The report notes that this material had a great insensitivity to impact and friction and an explosive power superior to that of other heat-resistant explosives,

(b)(3)

The third quarter report for 1972 states, "We have continued experiments to characterize the 90/10 TATB-Kel-F 800 material discussed last quarter, hampered somewhat by our limited stock of material. First deliveries of TATB from Pantex are expected soon to alleviate this shortage."[545]

The third quarter report also states, "The USAF and USN have studied the 'Final Report of the Phase 2 Feasibility Study of the High Yield Bomb,' dated March 21, 1972, ...and agree that it is technically feasible to develop a high-yield bomb that meets the stated requirements, with a minimum 4-yr development time, and that no bombs that meet the requirements of the HYB are currently available or in production. Subsequently, the Services have requested a Phase 3 Development Engineering program for the HYB.

(b)(3)

[543]D. P. MacDougall to Distribution, Subject: "Program Planning," ADW-204 (SRD) (February 28, 1972), 3 pp., B11. Drawer 49. Folder 1 of 5.

(b)(3)

[545]Leslie M. Redman and Cecil C. Carnes, Jr., "Quarterly Status Report on Weapons Research and Development for the Period Ending September 30, 1972 (U)," Los Alamos Scientific Laboratory report LA-5130-PR (SRD) (January 1973), pp. 53–54.

(b)(3)

The Laboratory's fourth quarter report for 1972 announced that a new full-fuzing-option (FUFO) bomb program had been requested. (This program took the place of the high-yield bomb program.) The bomb size was limited to a maximum of 18-in. diameter, 145-in. length, and a 2,400-lb weight. It was to have full-fuzing options and improved safety characteristics. It would be for delivery by both strategic and tactical aircraft.

(b)(3)

This new FUFO bomb program was a result of the review of the March 21, 1972, Phase 2 Feasibility Study of the High-Yield Bomb and the decision that certain aspects of the feasibility study should be expanded before a final decision was made on a Phase 3 development. In terms of design considerations, for the LASL proposals it was noted that, for safety reasons, it was desirable that the bomb incorporate use of the new insensitive explosive

(b)(3)

B. Mark 400 Program

1. Livermore vs Los Alamos: The Navy's Submarine-Launched Ballistic Missile (SLBM) Warheads—W47, W58, and W68

Navy planners and others realized that a ballistic missile outfitted with a nuclear warhead that could be launched from a nuclear submarine presented a weapon system that could be highly effective as a deterrent. This concept was placed into practice with the development of the first SLBM nuclear warhead: designated the W47. This warhead was designed for use with the Navy's Polaris A-1 and the Polaris A-2. It first entered the stockpile in June 1960. There were several modifications made in the warhead during its stockpile lifetime. The next warhead placed into deployment on a submarine-launched ballistic missile was the W58. This was used in the Mark 2 reentry system fitted on the Polaris A-3; this missile could carry three warheads. The weapon development groups at Livermore were responsible for these early warheads. The Lockheed Missile and Space Company (LMSC) carried the major responsibility for the carrier of the warhead(s). A detailed account of the development of the W47 and W58 is given in LA-13755-H (SRD). During the development of these systems, a close relationship was established between Livermore, Lockheed, and the Navy.

The early Livermore–Lockheed–Navy association was a close one. However, the administration at Los Alamos very much wanted to be included in this group. One way to get a foot in the door was to have Los Alamos people present at planning meetings. [Author's note: It should be noted that as an exception Ralph Williamson from T-2 participated in the group known as the Polaris Ad Hoc Group for Long Range Research and Development. He appears to have attended the meeting held on April 29–30, 1965, at the Naval Research facilities in Washington.[106] Although documentation is lacking, he probably attended similar meetings held at other times.]

In the fall of 1965, Al Bridges from Kaman Nuclear visited Los Alamos. At that time a request was made to him to have representatives from Los Alamos participate in the Navy's planning meetings. [Author's note: The administration at Los Alamos must have known that the Navy was interested in developing a new ballistic missile/submarine system to be called Poseidon.] On December 6, 1965, the Chief of Naval Operations requested that the AEC laboratories be authorized to cooperate with the Navy in joint conceptual studies leading to the determination of optimum parameters for various components of the Poseidon missile. This request in turn led to the inclusion of Los Alamos in a memo from Brigadier General Delmar L. Crowson, Director of Military Application. Crowson requested that the Sandia Corporation, the Los Alamos Scientific Laboratory, and the Lawrence Radiation Laboratory participate with the Navy in these requested conceptual studies.[107]

and firing (AF&F) system incorporating component technology developed during the Mk 3 program and other recent advanced development programs could be supplied.[123]]

The second meeting of the Re-entry Committee of the Fleet Ballistic Missile Steering Task Group was held on January 28, 1970, at the Naval Ordnance Laboratory (NOL) in Silver Spring, Maryland. It was reported that performance goals of the new ships to replace the Polaris/Poseidon ships were beginning to be outlined. The new ships would be on patrol 80% of the time with an 83-day patrol period. They would have a 7–15 db noise level below the present ships. They would include a long-life nuclear reactor. They would be designed with a collapse depth of 1,350 feet. For the missile launcher system, the tube dimensions being considered were a diameter of 115 to 135 inches and a length of 50 feet. The ships would each be capable of carrying twenty-four missiles. Each missile would have a minimum missile range of 4,500 nm. It was the missile that would be the determining factor in the size of the submarine. The missile candidates at that time ranged from the 34-foot long, 74-inch diameter C3 missile to a proposed 49-foot long 110-inch diameter missile. Several ship designs were under consideration, including a single hull vs several types of double hull configurations. Decisions still to be made included the number of missiles a ship should carry, launch tube diameter, launch conditions, number of people on each sub, shipboard environment requirements, ship/missile accuracy, and maintenance. The schedule then under consideration called for a nominal number of new-class ships by FY 1978. In terms of improvement in the warhead, it was indicated that with a suitable timeframe available for development, an explosive electric generator could be manufactured reliably. This type of generator would reduce the need for high currents for ignition. Improvements in CEP [circular error probability] were also possible. It was also reported that by using large reentry angles, high ballistic coefficients, and low radar cross sections, the offense could reduce the defense's engagement time. Hardening options were also presented at the meeting. It was recommended that the Navy spend "time and effort pursuing hardened system designs."[124]

(b)(3)

Although not part of the Mk 400 program, it will be noted that in the summer of 1970, the Navy was also interested in a program called CAFE. This stood for C-3, Alternate, Front End.

(b)(3)

[Author's note: There was concern at that time that, due to political considerations, that the use of the Mk 3/W68 (MIRV) might be restricted or abolished.] The first CAFE Reentry Interchange Committee Meeting took place on July 15, 1970. The LASL/SLA laboratories submitted data for the CAFE study in a document dated August 7, 1970. The principal warhead proposal from LASL was the use of a W67-like device. It was noted, "Many of the development tests, up to flight tests, have been completed for this device; construction drawings are available." Use of a 16M type of device was also

[123]"LASL/SLA Revised Data Package for ULMS (Undersea Long Range Missile System) Study," W-9-754 (SRD) (September 1, 1970), 12 pp., A99-019, 214-15.

(b)(3)

boat was to be six years after the IOC of the missile.

(b)(3)

The Packard memo had also asked the Navy to consider an optional RB that had a maneuvering capability.[147]

(b)(3)

[Author's note: This was good news for the Los Alamos group. It appeared that a Los Alamos proposal was being used in the RB design studies.]

There was also the Small Evader Experiment (SEE). During the October 20, 1971, meeting of the WWG, Gillespie informed the attendees that SEE was a minimum-weight, minimum-size maneuvering warhead for Poseidon. General Electric personnel planned to have the SEE project in a study phase through December; flight tests were to begin as quickly as possible after that. (b)(3) Gillespie reported that the LASL group felt that they had a better design for this application. Gillespie also reported on the EXPO program. He noted that EXPO had, in essence, been renamed ULMS. The Phase 1 would require a new missile for the Poseidon boat; two alternative missile developments were desired.

(b)(3) /For this system, the Navy's SSPO was trying to avoid the usual Phase 2 program by repackaging the W68 as the warhead. The second alternative missile development would be concerned with a missile that would carry a maneuvering reentry system similar to SEE.[149]

On October 20, 1971, a meeting was held at the Sunnyvale offices of LMSC. T. P. Seitz and F. B. Baker from W-9 were the Los Alamos attendees. Their trip report indicates that the discussions centered on the status of the ULMS/

(b)(3)

The reentry body was limited to a weight of 170 pounds, a length of 65 inches, and a diameter of 15.8 inches.

fabrication facilities." (b)(3)
Additional information is available in the cited reference.[196]

(b)(3)

The final draft of the Phase 2 feasibility study report was also released in the summer of 1972. (b)(3) In the Los Alamos files the draft study report carries a date, made in pencil, of July 1, 1972. The cover sheet for the document carries a date of June 26, 1972. As previously noted, during the second meeting of the Mk 400 mini-POM group held on June 28, 1972, it had been announced that the Phase 2 report had been approved.]

(b)(3)

The final yield of the new warhead had not yet been specified.

(b)(3)

(b)(3)

16-inch base diameter in the RB. This is the base diameter used in the design of the W76.] Near the end of his trip report, Sandford included several pieces of interesting "gossip." He reported, "At DDR&E we talked to John J. Brett who seemed to react favorably to our new, higher yield proposals. At the SPO we briefed Cdr. Stinner, Mark Messerole, and Hal McMasters. They seemed relieved and/or amused that our WHs now were competitive with LLL's WHs." In addition, Sandford reported, "At DMA we briefed General Camm, Tom Clark, Col. Haidler, and several of their staff members. The briefing went very well with several pertinent questions being asked." Furthermore, Sanford reported, "The MK-400 I&C study indeed was stuck in the AEC.

(b)(3)

Pending resolution of this problem, the Phase 3 request cannot be sent to DMA." It was also noted in the trip report that the question of the requirements for special nuclear material had been discussed by Tom Clark. The trip report states, "The only concrete message gleaned from Clark's talk was that one or two reactor restarts at Savannah River are feasible but the AEC does not want to restart any of the Richland reactors." [203]

Despite this report from Hoyt and Sanford of the delay in the I&C study, on August 17, the AEC proposed to send the AEC Impact and Capability study to Foster at the Defense Research and Engineering, Department of Defense. As to the reactor question, the proposed cover letter for the study noted, "In addition, we believe that, while restart of up to four reactors is theoretically possible, in light of decisions which have been made in the past the restart of the two standby reactors at Savannah River would be difficult enough to achieve; the restart of additional reactors at Richland might pose intractable problems, particularly in view of current environmental concerns." The letter added, "Certain adjustments to the assumed Mk 400 delivery schedules and to the assumed base stockpile might possibly reduce the number of reactor restarts required." The letter ended by stating, "In order to meet the desired IOC date of December 1977 it will be necessary for us to receive a Phase 3 decision by the end of August so that the AEC can arrange for the necessary capital funding."[204]

(b)(3)

He included attachments of the vufoils that had been used in the August 7 briefing given to Assistant DDR&E Director John J. Brett.[205]

reductions associated with nose radii greater than optimum, they were considering a self-deploying aerospike on the nose fairing of the C4 missile.

(b)(3)

The flight test program was also discussed. The AF&F sequence of the Mk 400 was also reviewed. There were several presentations made during the meeting on the possible types of overcoats that might be used to reduce vulnerability.[214]

The quarterly progress report from the Laboratory for the period ending September 30, 1972, noted that for the Mk 400 there had not been a Phase 1 program. Phase 2 had been informally started in November 1971; however, the formal direction from DMA to participate in the Phase 2 had not been received until February 3, 1972. The LASL Phase 2 data package had been submitted on February 28, 1972. Although the final Phase 2-study report had been dated July 1, 1972, the report had not been formally distributed by SSPO until September 1972. In August 1972, the LASL groups had presented to SSPO, DDR&E, and DMA representatives the new design improvements that had been made. In turn, new reentry-body weights for the new warhead proposals had been developed.[215]

The Trident system was discussed at length during the October 5, 1972, meeting of the Theoretical Weapons Group (TWG). Gillespie stated that the purpose of the Fleet Ballistic Missile System was to provide deterrence through an invulnerable force capable of inflicting unacceptable damage to the Soviet urban/industrial complex. Gillespie noted that by treaty the United States was limited to 44 submarines. As of October 1972, the U.S. had 10 Polaris submarines that carried the A3 missile. (b)(3)

There were 31 Poseidon submarines that carried the C3 missile (b)(3) The new Trident would carry the C4 missile.

(b)(3) Trident had an IOC of 1978. It was twice as large as the Poseidon boat and could carry the larger D5 missile.

(b)(3)

Gillespie also noted the importance of minimum weight in terms of maximum range. Gillespie then discussed, assuming that LASL was assigned the Phase 3 in January 1973, the future test program

(b)(3)

Several additional tests would be necessary before a final weaponized design was achieved. The minutes of the meeting state, "In closing, Gillespie outlined the reasons for supporting LASL as the recipient of the MK 400 Phase 3 in terms of past experience, the present LASL program and the availability of program support

. (Phase 3 development of the W76 WH for the Mk 4 RB was awarded to LASL and SLA on April 27, 1973.)"[264]

11. Significance

It had been a long and at times bitter fight. But the laboratory at Los Alamos had won the long desired strategic warhead assignment. However, the laboratory staff was now under extreme pressure to develop and design a warhead that would (1) meet the yield requirement, (2) meet the size and weight requirements, (3) achieve the vulnerability and safety requirements, and (4) at the same time satisfy the minimum number of NTS development tests, the strict time restraints, as well as the budget limits that had been placed on weapon development.

It was never envisioned that the in the year 2003 planning would be in progress to retain the W76 in the U.S. stockpile.

C. Harold Agnew

1. Proponent

While the entire staff at Los Alamos worked hard to obtain the Phase 3 for the Mk 400, one of the chief proponents for this award was Harold Agnew. (From the information given in Chapter I, the reader will recall that Agnew became Laboratory Director in 1970.) Agnew felt that there were many reasons why the award should go to Los Alamos

(b)(3)

[264]Leslie M. Redman, "LASL Weapons Quarterly (U), for the Period Ending June 30, 1973," Los Alamos Scientific Laboratory report LA-5401-PR (SRD) (September 1973), p. 58.

7. Yield: The Confetti Argument

Agnew felt that the yield of the W68 was too low to be really effective. In addition, in terms of the overall total yield available from all the W68 warheads, the W68 design was very costly in terms of the amount of required special nuclear materials.

In an April 1972 TWX to Assistant Director for Safety and Liaison (Division of Military Application) Colonel Robert T. Duff, Agnew reported that he was worried about maintaining the U.S. nuclear deterrent. Agnew noted, "It occurs to me that as we go to lower and lower yields in our strategic missile warheads and the Soviet Union builds up a better and better civil defense position, the reality of this deterrent may become questionable.

(b)(3)

If the Soviet leadership believes this, then our strategic deterrent will have lost a good deal of its force. If our MIRV trend continues we'll be threatening to throw confetti at a potential aggressor. Confetti has high penetration and survivability but little deterrent power."[281]

In a letter dated October 10, 1972, to Giller, at that time Assistant General Manager for National Security, Agnew again noted several reasons why low yield warheads might not be the best solution for maximizing the deterrence capability of the stockpile. He reported that considering the number of required submarines and the low efficiency in their use of special nuclear material, the low-yield warheads were not very cost effective. Moreover, Agnew pointed out that for the Hiroshima device, the effects on Hiroshima in terms of loss of substantial buildings and the people in them "wasn't all that impressive." In terms of loss of life, the USSR had lost more than ten million people in WWII. Although the Soviets had an extensive civil-defense network in place, even if that did not work to reduce loss of civilian lives, the Soviets might not mind losing a few people. Agnew wrote, "Again, to me, to continue to increase warhead numbers at the cost of a decrease in yield per warhead could eventually lead to no deterrence in the minds of those we hope to deter." Agnew stated, "I feel very strongly that we should endeavor to convince the DoD that what they should have on the next round is a mix of yields.

(b)(3)

8. Capability

Agnew in his August 10, 1972, letter to Camm pointed out that the Los Alamos group had been developing suitable technology applicable to the new strategic missile warheads. He wrote, "In summary then, we have been working very hard to provide the very latest technology in warhead designs incorporating the most advanced minimum weight hardening techniques to provide an optimum warhead for the next round of strategic missile warheads. In fact, our work has been of such outstanding quality that we have been invited by Admiral Levering Smith to

[281]H. M. Agnew, University of California, Los Alamos Scientific Laboratory, Los Alamos, N.M. to BY3/Colonel Robert T. Duff, USAF, Assistant Director for Safety and Liaison, Division of Military Application USAEC, Wash., D.C. (SRD) (April 14, 1972), pp. 1–2, B11, Drawer 56, Folder 1 of 4.

(b)(3)

join his Steering Task Group for the FBM Weapon System Program in anticipation of our supplying TRIDENT with its warhead."[283]

Agnew felt that the LASL group had had extensive experience in the areas of vulnerability, hardening, and RV/warhead integration. Again, in a letter to Camm dated September 11, 1972, Agnew wrote, "Also, our in-house work and underground testing program in the vulnerability and hardening area have made a significant contribution to the nation's overall capability in this area." He also noted, "One unique advantage we have is that while we have a solid background of experience in reentry system design we are not tied to our past achievements and thereby inhibited in our approach to new designs."[284] In his November 27, 1972, letter to Camm, Agnew gave examples of how the LASL team had been the leader in several aspects of the vulnerability program.

(b)(3)

This experience had been demonstrated in the successful Mk 18 and Mk 400 programs. With money very tight and the need to limit the expense of testing at NTS, the LASL team was in the best position to develop the Mk 400 warhead with a minimum number of tests. Agnew told Camm, "Once the Phase 3 has been awarded, we will design a package in which both the primary and secondary are so configured as to provide the best possible warhead to satisfy the specific DoD requirements."[286]

9. Promise of the Next Strategic Missile Warhead

In his August 10, 1972, letter to Camm in which Agnew discussed the history of previous weapon assignments, Agnew noted that at the time of the Mk 3/W68 warhead assignment to Livermore the Los Alamos group had been promised the development responsibility "for the next strategic missile warhead, whatever it might be..."[287]

In a letter dated September 11, 1972, to Camm, Agnew again reminded Camm that LASL had been told that they would receive development responsibility for the next strategic reentry system. To meet this obligation, the members of the LASL weapon groups had been developing and testing warheads for the Mk 19, Mk 18, ABC, and Mk 400 programs. This work had resulted in the Laboratory being very involved in these types of systems. (b)(3)

Agnew reported, "These two tests cover the spectrum of possible secondary designs for the MK 400." Agnew also noted that the design of a suitable primary for the Mk 400 program was underway. He concluded his September 11 letter by stating "We feel

that our past experience with Mk 18 and ABC, together with our current Mk 400 efforts, will enable us to continue this [successful effort] for the Mk 400 warhead."[288]

10. Morale

Agnew was fearful concerning the effect that an award of the Phase 3, Mk 400 warhead to Livermore might have on Los Alamos weapon personnel. Agnew in his November 27, 1972, letter to Camm noted, "After having had the vision to work in this field and having been extremely successful, not to receive this assignment would have a very severe impact on our staff morale."[289]

A SHORT HISTORY OF THE U.S. NUCLEAR STOCKPILE: 1945–1985 (U)

Raymond Pollock

ABSTRACT (U)

This report, one in a series concerned with the history of nuclear-weapons research and development, examines the evolution of the U. S. nuclear weapons stockpile. The report distinguishes between weapon requirements resulting from strategic and operational demands and requirements created by technological advances. The acquisition of nuclear weapons through four distinct, evolutionary phases is also reviewed.

INTRODUCTION

The purpose of this report is to identify the possible causes of significant change in the U.S. nuclear-weapons stockpile as it evolved between 1945 and 1985. While we will be concerned with the relationship between stockpile characteristics and national security policy, we concentrate on qualitative changes rather than on inventories. Our principal interest is to distinguish between weapon requirements generated by strategic and operational demands and those resulting primarily from opportunities created by the advance of technology.

As a first step, we examine the diversity of the U.S. nuclear-weapons stockpile, or more particularly, its variation over time. Figure 1 shows the total number of distinct weapon systems (as distinguished by mark number), both strategic and tactical (nonstrategic) weapons. The bar charts of Fig. 2 indicate, for the strategic category, system entries and retirements; the net of these determines the data points of Fig. 1. Figure 3 shows entries and retirements for nonstrategic systems. Examination of these figures leads to the conclusion that between 1945 and 1985 the U.S. nuclear-weapons acquisition process proceeded in four distinct phases.

In the early postwar phase (1945–1950), the stockpile remained based on the wartime Fat Man and Little Boy designs. Air Force heavy bombers provided the only delivery vehicles, and the "atomic" bomb was clearly seen as solely a strategic weapon of awesome power.

During the second phase (1950–1955), the variety of stockpiled systems grew quite rapidly, as the results of postwar R&D allowed lighter, more efficient fission bombs to be developed. New, heavier bombers made possible the entry into stockpile of the first huge, high-yield, "emergency capability" thermonuclear weapons. And the first weapons developed especially for tactical applications made their appearance.

May 1949, a study headed by Air Force Lt. General H. R. Harmon reported that even if all 133 weapons detonated on target the Soviet leadership would not be critically weakened, Soviet military ability to take selected areas of Western Europe and of the Middle East and Far East would not be seriously impaired, and Soviet industrial capacity would not be sufficiently reduced to prevent recovery. The resulting reassessment of targeting requirements led to a substantial increase in nuclear production. And in the fall of 1949, the Joint Chiefs of Staff (JCS), in conjunction with the North Atlantic Treaty committing the U. S. to European defense, tasked the Strategic Air Command with "retardation of Soviet advances in Western Europe."[1]

With General Curtis LeMay as SAC commander, and freed by the results of Sandstone from the constraints of weapons scarcity, the 60 nuclear-capable aircraft available at the end of 1948 grew to 250 by June 1950. The giant B-36 came on line in 1949, and the all-jet B-47 medium bomber would arrive in 1951. The October 1949 target annex for war plan OFFTACKLE called for attacks on 104 urban targets using 204 weapons, with 72 bombs to be held in reserve.[2] The prime objective was still disruption of the Soviet will to fight, but a number of "retardation" targets were included. By August 1950, concern over growing Soviet nuclear strength led to a further re-prioritization to assign first priority to targets supporting Soviet nuclear-delivery capability. The mission of retarding a Soviet attack in Europe was assigned second priority, and disruption of Soviet war-making capacity by attacks on electric power, atomic energy industries and liquid fuel facilities was assigned third priority. This war-fighting allocation system persisted in U. S. targeting doctrine for the next 10 years.

The move away from simple urban targeting to a more elaborate military targeting doctrine designed to meet specific military objectives was to a large degree made possible by the increasing availability of nuclear weapons, and this move, in turn, stimulated the need for new weapons.

DOE (b)(3)

For the European retardation mission, which needed to deal with somewhat transitory targets, the relatively lightweight B5 tactical bomb entered stockpile in 1952. This was followed in short order by a series of new tactical weapons, including development of the Mk-9, 280-mm artillery shell; adaptation of the B5 as the W5 warhead for the Navy's Regulus and Air Force Matador cruise missiles; and development of the W7, as both bomb and warhead for the [redacted] short-range missiles, and as the first atomic demolition munition (ADM). All of these were implosion weapons, with the exception of the 280-mm artillery-fired atomic projectile (AFAP), which was gun-assembled. Interestingly, the gun-assembled B8 bomb ("Improved Little Boy") also entered stockpile in 1952 and remained for nearly 6 years.

Turning again to the strategic arena, a growing perception that many critical Soviet targets were harder than previously expected, and often covered a large area or were grouped such that "bonus" damage could be achieved with a large enough weapon, drove the quest for higher yields. Boosting was first tested in the Item shot in the 1951 Greenhouse series, and it appeared clear that megaton-yield, boosted fission weapons of reasonable weight and size could be developed. But it was also apparent that the thermonuclear weapon, first considered by Edward Teller and others in a 1942 meeting in Berkeley, would offer an economical route to very high yields if it could be made to work. And the boosted fission explosive offered the possibility of an energy source small and hot enough to provide an ideal primary stage for the practical thermonuclear concept developed by Teller and Stanislaw Ulam.

The controversy surrounding President Harry Truman's decision to go forward

Jupiter. Perhaps even more significant, the feasibility of solid-fueled missiles made the submarine a practical ballistic-missile-delivery platform, and in 1956 the Navy committed to developing Polaris.

But while the strategic forces grew and diversified, SAC doctrine of massive retaliation and emphasis on counterforce targeting, with its apparently unlimited requirements for weapons, came under steady attack within the Joint Chiefs of Staff (JCS). In the spring of 1958, a JCS majority under the leadership of Army Chief of Staff General Maxwell Taylor argued for the need to prepare for limited war. Secretary of State John Foster Dulles agreed that, with the Soviets now a major nuclear power, the doctrine of massive retaliation had outlived its usefulness. President Dwight Eisenhower, however, felt that an increase in conventional forces could be bought only at the cost of increased defense expenditures, which he would not accept, or of weakened strategic (air) forces, which he could not accept without further study. He tasked the National Security Council (NSC) to give high priority to a careful analysis of the minimum requirements for deterrence and retaliation.

Redacted

In July 1958, Admiral Arleigh Burke weighed in with the Navy's strategy to exploit the flexibility and invulnerability of the coming Polaris force. Burke argued that, while it had once made sense for the U. S. to deploy sufficient force to disarm the Soviet Union, the growing Soviet intercontinental ballistic missile (ICBM) deployment made this "blunting" or disarming mission now unworkable. In addition, the Soviets could now put at risk all U. S. land-based forces; their vulnerability invited surprise attack. The alternative was to secure the U. S. strike force by mobility and concealment, eliminating the pressure to preempt and allowing the U. S. to respond selectively in order to apply political coercion. This strategy of "finite deterrence" would require a small submarine-launched ballistic missile (SLBM) force sized for deterrence alone (i.e., the ability to destroy major urban areas).

Recognizing the Navy threat, SAC in November 1958 proposed that a U. S. Strategic Command embracing all strategic forces, including Polaris, should be formed, with the Air Force in charge. SAC would then be abolished. Burke admired the idea of dismantling SAC, but rejected the notion that anyone but sailors could operate Polaris submarines in conjunction with other naval forces. He also saw no need for any new coordination structure since Polaris would use its missiles against a (Navy-determined) target system that was generally stable..

Despite Admiral Burke's assurances, the problem of controlling and coordinating U. S. nuclear retaliation was growing more serious—even in the absence of Polaris. Thoughtful Air Force leaders believed that an overhaul of "atomic coordination machinery" was overdue. In March 1959, JCS Chairman General Nathan Twining wrote a memo to Secretary of Defense Neil McElroy addressing "Target Coordination and Associated Problems." This memo triggered no immediate action but laid the groundwork for the later formation of the Joint Strategic Target Planning Staff (JSTPS).[3]

In the last year of the Eisenhower administration, the divergence of strategic planning combined with the above considerations to create a situation that demanded resolution. President Eisenhower had grown increasingly dubious about the seemingly endless growth in Soviet targets, but, in the absence of any alternative, had acceded to SAC demands for additional weapon platforms and nuclear-weapons production. In March 1960, the Air Force Intelligence Directorate (AFID) identified [redacted] targets and projected that this total would grow to [redacted] by 1965 as the Soviets added offensive and defensive missiles. Highest priority was assigned to suppressing Soviet air defenses and stopping Soviet nuclear attack on the U. S. and its allies. Halting Soviet land and sea operations (the retardation mission) re-

DOD 1.5(c) 6b-1

had been consolidated into the JSTPS, and the first SIOP was in effect. Nuclear support for the North Atlantic Treaty Organization (NATO) in the theater had been prepared and the weapons to implement NATO MC 14/2 were in procurement. The list of strategic weapons that entered stockpile during the last 5 years of the Eisenhower administration attests to the vigor of the nuclear production complex:

B28 (thermonuclear bomb)
B36 (thermonuclear bomb)
B39 (thermonuclear bomb)
B41 (thermonuclear bomb)
W28 (thermonuclear warhead: Hound Dog, Mace)
W39 (thermonuclear warhead: Bomarc)
W47 (thermonuclear warhead: Polaris A1, A2)
W49 (thermonuclear warhead: Thor, Jupiter, Atlas, Titan I).

The list of tactical weapons is equally impressive:

W25 (fission weapon: Genie air-to-air defense missile)
W27 (thermonuclear warhead: Regulus II)
W30 (fission warhead: Navy Talos, TADM missiles)
W31 (fission weapon: ADM.

W33 (gun-assembled fission weapon: 8-in. artillery shell)
W34 (multipurpose fission warhead: Hotpoint).

The momentum built up during the Eisenhower years carried over into the Kennedy Administration, even though Defense Secretary Robert McNamara found SIOP-62 too rigid and apparently lacking in strategic rationale. The new administration initiated a rethinking of strategy and doctrine and introduced flexible options into the SIOP, but did not slow the entry of new weapons into stockpile. As a result, by the end of 1965 the following additional nuclear systems had become operational:

Strategic:

W38 (thermonuclear warhead: Atlas, Titan I)
B43 (thermonuclear bomb)
W53 (thermonuclear warhead: Titan II)
W56 (thermonuclear warhead: Minuteman II)
W58 (thermonuclear warhead: Polaris A3)
W59 (thermonuclear warhead: Minuteman I).

Tactical:

W44 (fission weapon: ASROC)
W45 (fission weapon: MADM, Little John, Terrier, Bullpup)
W48 (fission weapon: 155-mm artillery shell)
W50 (thermonuclear warhead: Pershing I)
W52 (thermonuclear warhead: Sergeant)
W54 (fission weapon: Falcon, Davy Crockett, SADM)
W55 (thermonuclear warhead: SUBROC)
B57 (multipurpose fission bomb).

Except for the gun-assembled W33, which required extensive field assembly before firing, all stockpiled weapons were now sealed-pit designs. While there was much innovative detail, and a few really new wrinkles yet to be worked out, the major inventions had been made and heavily exploited, and the basic patterns of nuclear-weapons technology had been firmly established.

THE STOCKPILE FROM 1965

Since 1965, the growth in the nuclear-weapons stockpile has shown a character entirely different from that of the first two decades. Referring once again to Figs. 1 and 2, we see that only 23 new systems entered stockpile in the 20 years 1966–1985 and that 15 systems were retired during this period. The functional makeup of the stockpile, that is, the proportions dedicated to strategic and nonstrategic missions, remains steady at the pattern established by 1965. This pattern is consistent with a view that little change in fundamental U. S. nuclear strategy has taken place over the last 20 years. Apparently, no nuclear innovation during this period has been sufficiently dramatic to once more induce sea changes like those of the 1940s and 1950s. To a large extent, turnovers in the stockpile appear designed to make more effective use of the technologies first developed in the 1950s in order to match weapon systems to military requirements.

This is not to say that the art and science of nuclear weaponry has not advanced during the modern era. Steady progress in basic weapon technology and a few major technical innovations have substantially enhanced the operational and logistical utility of nuclear weapons. To examine this in detail, we shall in the balance of this report adopt an organization centered on distinguishing weapons by the operational requirements they are designed to fill. Specifically, we shall develop the history of the stockpile in seven different categories:

- Strategic offensive: land-based ballistic missiles
- Strategic offensive: sea-based ballistic missiles
- Gravity bombs
- Air-to-surface missiles
- Tactical missiles
- Defensive weapons
- Miscellaneous tactical weapons.

Before a chronological survey of stockpile development is resumed, the more important advances of the past 20 years will first be described.

Basic Knowledge

While not an identifiable single technology, increased knowledge of basic weapon physics, materials properties and behavior, electronics, and computing technology have resulted in substantial steady improvements in nuclear-weapons design and construction. Weapons designers have been able to use their understanding of the physics of weapon function, plus the marked improvement in their ability to model weapon behavior, to eliminate unnecessary weight and fit a given yield into a smaller envelope. At the same time, miniaturization of weapon electronics and the development of new structural materials have made it possible to use more of the total warhead volume for the nuclear physics package. The result has been a steady improvement over the years in the yield-to-weight ratio, reductions in warhead diameter and size, and the ability to tailor weapons to particular delivery modes.

Safety

It is noteworthy that, over the span of more than 40 years, there has never been an accidental detonation of a nuclear weapon that produced a nuclear yield. However, there have been accidents with nuclear weapons, and there have been accidental detonations of high explosive (HE) in nuclear weapons. Requirements for one-point safety adopted and enforced many years ago have ensured that, even in the event of an accident sufficiently severe to detonate the HE of a nuclear weapon, no significant nuclear yield will result. However, explosion and fire can still result in the dispersal of weapons materials—most notably plutonium—that still present a significant hazard to indigenous populations and cleanup personnel. The most noteworthy such event occurred in 1966 near Palomares, Spain, when a B-52 carrying four

While controversy over MX basing has clouded the program almost from its beginning—and is not yet completely settled—the process of choosing a warhead for MX was also not serene.

DoE (b)(3)

Segments of the Air Force strongly opposed this, however, arguing that Soviet construction of a new generation of "superhard" missile silos, control centers, and leadership bunkers made it imperative that the MX be used to improve U. S. hard-target kill capability. The March 1976 imposition of a 150-kt limit on nuclear test yields by the Limited Test Ban Treaty (LTBT) complicated the decision process. This meant that a new high-yield warhead for MX would have to be fielded without ever undergoing tests in its complete design configuration. Advocates of hard-target kill won the day fairly early on, but the specifics of the warhead remained uncertain for some time; for an extended period the W78 Mk-12A was carried as the baseline MX warhead. However, in early 1982 the Department of Defense (DoD) chose a new warhead, the W87, to be mated with the new Mk-21 reentry vehicle.

The W87 began the modern era of treaty-constrained development of high-yield warheads.

DoE (b)(3)

Sea-Based Strategic Ballistic Missiles

October 1965 saw the last ballistic-missile nuclear submarine (SSBN) patrol of the Polaris A1 missile and the start of development of the Poseidon C3 missile for the new Poseidon boats. Only 5 years after the first Polaris SSBN had gone on station, the Navy was retiring the earliest elements of its first-generation SLBM force and was entering development of a second, MIRVed generation.

DoE (b)(3)

Neither of the Polaris versions offered very good delivery accuracy, nor would this be a requirement on the yet-to-be-developed Poseidon C3. The primary mission of the SLBM force seemed to be to provide a secure retaliatory force, either to meet the requirements for finite deterrence, spelled out 10 years earlier by Arleigh Burke, or to pave the way for SAC bombers by knocking out defenses, as stipulated by President Eisenhower. In any case, the SLBM force was clearly designed for soft targets.

DoE (b)(3)

The Trident program began as ULMS—Undersea Long-Range Missile System—in 1969 as a result of the STRAT-X studies. As a follow-on to Polaris/Poseidon, Trident was envisioned as a quieter submarine, carrying missiles that could be launched at intercontinental range. The need for Tri-

dent was driven by two primary considerations: a replacement for Poseidon would be needed before the end of its projected service life of 20 to 25 years, and the replacement submarines should operate over a wider range of ocean in order to ensure survivability against a growing Soviet surveillance and ASW capability. Development of the Trident I C4 missile and the Ohio-class Trident boat was approved by the Secretary of Defense in September 1971.

The Trident I missile was sized to allow retrofit into the smaller Poseidon SSBNs—a later Trident II missile will fit only the larger Trident boats. By the time the W76 warhead for the C4 was selected in 1973, the Navy had become more interested in missile range than in any further fractionation of payloads.

DOE b(3)

The W76 is the latest SLBM warhead to enter stockpile.

DOE (b)(3)

complete the Navy's conversion from concentration solely on soft targets.

DOE (b)(3)

Gravity Bombs

The story of gravity bombs since 1965 is to a large extent the story of the B61 bomb in all its variants. The B61, which entered Phase 3 development in January 1963, is a multipurpose modern tactical bomb, weighing approximately 700 lb, which now exists in eight models designed for air delivery by both strategic and tactical forces. Because the B61 is a truly multipurpose weapon, carried by a wide variety of U. S. and Allied aircraft dispersed all over the world, the development and refinement of B61 mods has been heavily influenced by requirements for safety and security. All B61 variants but one carry Permissive Action Link (PAL) arming systems, and some of the earlier mods that predated the introduction of IHE are now being replaced by versions employing an IHE primary and more elaborate safety and security systems.

DOE (b)(3)

The Mod 0 employs a Category B PAL, requiring entry of a four-digit code to arm the weapon. The Mod 1 does not have the PAL (it is intended for Navy use); otherwise, it is identical to the Mod 0. Both of these early versions use PBX9404 HE.

DOE (b)(3)

his version also incorporates command disable, which will destroy critical components of the warhead on coded command. The B61 Mod 5 is the last of the non-IHE versions.

DOE (b)(3)

Beginning with the Mod 3, IHE has become standard equipment for B61s, along with weak link/strong link and unique sig-

in the strategic stockpile. Simultaneously, the intensified Soviet threat to Europe and the consolidation of U. S. nuclear strategy led to the introduction of large numbers of weapons designed for tactical/theater applications. During this period, the three legs of the strategic triad were established and the first SIOP was developed. While progress in nuclear-weapon technology continued to play a major role, technical advance across a broader front, including electronics and ballistic-missile technology, became very important. This era, perhaps more than any other, displays the symbiosis of nuclear and nonnuclear technologies in both prodding and responding to military requirements.

The fourth phase, extending from about 1965 to 1985, might be characterized as largely a period of refinement. While the total number of stockpiled weapons has varied over these years, the number of distinct types—mark numbers—has stayed relatively constant until the recent Reagan administration buildup. Second- or even third-generation warheads have replaced earlier systems, offering quantitative improvements in performance and operational characteristics. Technical advance in the state of the art in nuclear weaponry has continued, but military requirements have become the dominant force in determining the shape of the stockpile.

2ND REVIEW DATE: 11/16/93 AUTHORITY: ADC NAME: Kirsch

On Monday there will be a discussion in the Tech Council concerning the Laboratory program and in particular concerning the question whether our effort can be so increased as to make the Super Bomb feasible within the foreseeable future. I should like to present to you my views on this matter in this memorandum. In this way, I hope that more thought can be given to the question before Technical Council convenes.

I would like to outline why it is essential for us to develop a Super Bomb at the earliest possible time or else be able to say with reasonable confidence that the Super is not feasible. The arguments that have led me to this conclusion are of various kinds.

[redacted]

POLITICAL CONSIDERATION:

It is my conviction that a peaceful settlement with the Russians is possibl only if we possess overwhelming superiority. We do not now possess such superiority. The most promising prospect to acquire a great lead is by an early development of a Super Bomb. I am sure that such an accomplishment will in itself not solve the problem. Most difficult political questions will also have to be solved. But early possession of the Super Bomb will give us another chance in the political field. Without a Super Bomb such another chance is not likely to arise.

RUSSIAN PROGRESS:

The fact that an atomic explosion took place in Russia at this early a date has considerable significance. It seems that the Russian rate of progress is at least comparable to, if it does not exceed, the rate of progress in this country. The Russians have started working on the atomic bomb approximately in the summer of 1945. They are likely to have given consideration to the problem somewhat earlier but it is hardly probable that the total time of reasonably intensive effort in Russia has exceeded five years. This time is approximately the same as the time that was needed in this country to make and to explode an atomic bomb. Thus the rate of progress in R[redacted] is comparable to the rate at which we have been working during the [redacted] present rate of progress in comparison is far slower than in war[redacted]

It is probable that the Russians did not explore as many po[redacted]es bef[redacted] achieving an atomic explosion as we did. It is also prob[redacted] the Russians have not put into their atomic development th[redacted] horough and elaborate scientific and technical effort as we did. [redacted] therefore claim that their accomplishment is not equal to our wartime a[redacted]mplishment. If this is so, however, it merely proves that the elaborate precautions which we took in our atomic development was not absolutely essential. If the

Russians continue to make actual progress faster and if we lose the atomic armament race, it will make little difference whether the reason has been the particular brilliance of Russian scientists or the exaggerated caution and thoroughness of our own group. [redacted]

A detailed possible picture of the Russian progress can be imagined along the following lines:

The Russians probably were familiar with the plans for the Canadian heavy water pile. The captured German scientists also knew of plans for heavy water piles. There are two major technical difficulties in the construction of such a pile. One is the fabrication of metallic uranium. This the Russians have probably learned from the Germans. The other is the production of great quantities of heavy water. There are several ways to accomplish this. One of the best techniques is the distillation of liquid hydrogen. The necessary low temperature technique is quite well developed in Russia. The Russians may therefore have had a pile of the approximate efficiency of the Chalk River pile as early as 1948 or even 1947. The extraction of plutonium from such a pile is a difficult job but can be more easily accomplished if the precautions taken for protection of personnel are less elaborate than those taken in this country. Such precautions are and must be a paramount consideration in our country but the same is not the case in Russia. A pile of the Chalk River type working steadily at 30 megawatts can produce material for a trinity bomb in less than a year. It can produce material for a gun gadget in two years. It is quite possible that the Russians have made a successful implosion. It is also possible, although perhaps somewhat less likely, that they have used the gun assembly and that the actual nuclear explosion was performed with a relatively inefficient gun gadget.

The above description gives the Russians credit for a minimum of scientific and technical progress. Even if this minimum is accepted, further Russian progress can be anticipated along the following lines. The Russians probably will build further heavy water piles. They may also build small piles working with some of the plutonium which the heavy water piles produce. These aims can be rapidly accomplished if no excessive demands are made with respect to high flux, resistance of materials for irradiation or with respect to breeding properties. The Russian rate of production of plutonium may equal the rate of our production within a year and indeed we have no absolute assurance that our production has not been already surpassed. It is therefore not impossible that the Russians should overtake us even in the matter of the stockpile which is the one item which never has been neglected in the United States.

An even more dangerous situation seems to exist with respect to neutron excess. This neutron excess is much greater for heavy water piles than it is for graphite piles and of course even greater for plutonium piles. [redacted] it is reasonable to assume that the Russians either are already ahe[redacted]n this respect or will be ahead of us in the near future.

The number of available excess neutrons is of decisiv[redacted] in several war time applications of atomic energy. [redacted] Among the[redacted]duction of tritium is probably the most important since tritium [redacted]uction is an important component in the production of the Super Bomb.

[redacted]

One of the first objectives would be to step up the date on which one can hope to produce a successful booster.

DOE
6(3)

TIME SCHEDULE:

If the Laboratory can marshall the necessary support from Washington for a really vigorous program, the problem of construction and detonating of a Super might be attacked with the same speed with which similar problems were attacked during the war. I realize that this program calls for an all out effort. However, I do not believe that anything less than such an all out effort would be commensurate with the responsibility which this Laboratory has undertaken with respect to the ultimate safety of the nation. It will be essential that all members of the Laboratory contribute fully any ideas they may have how to accomplish the technical details of this job.

incorporated in dispersed weapons can be made solely in terms of broad policy considerations as to the desired objective."

[redacted]

DOE b(3)

1.3.1.2 PAL General Characteristics (U)

(U) In September 1962, the Secretary of Defense approved a set of DoD design guidelines for PAL systems. These guidelines, entitled "General Characteristics for Permissive Devices for Use With Nuclear Weapons," or revisions thereof have served since that time as standards in specifying PAL devices in the MC of new weapons systems. The original guidelines and the four revisions (1969, 1970, 1972, and 1980) are included in Appendix B.

(U) The statement of purpose in the first edition of the General Characteristics of PAL defines:

> (U) "an arming control device for use with designated nuclear weapons which is intended to provide some additional physical means for preventing unauthorized use of nuclear weapons."[18]

(U) A number of specific design requirements are included. Most of these relate to specific operational features of the PAL system or to issues of compatibility with the rest of the weapons system. For instance, the PAL system

- (U) must not degrade weapon safety or reliability
- (U) must he compatible with weapon operational concepts as stated in the STS
- (U) must not significantly lengthen the reaction time for the weapon system

(U) These requirements are restated in all subsequent versions of the General Characteristics. However, as suggested in the Weisner memo, the objective of this system and its reason for existence is based on its ability to protect the weapon against unauthorized use by a potential adversary. Of the twelve specific design requirements stated in the original document, only one relates to the performance of PAL against an adversary.

[redacted]

DOE b(3)

(U) Thus, the objective in terms of an adversary is not specified. However, some bounds are placed on the adversary's capabilities. The *function* of PAL is stated in terms of delay following unauthorized access to a weapon.

(U) In the 1969 edition, the stated purpose is

(U) "To provide general characteristics for permissive action links incorporated in weapons systems to prevent unauthorized nuclear detonation."[19]

[redacted]

DOE b(3)

C b(1)

(U) In 1972, a new edition was prepared to include all existing PAL technology. While the statement of purpose remained essentially the same as in the 1969 edition, PALs are defined as

> (U) "devices and subsystems designed to reduce the possibility of obtaining a nuclear detonation from a nuclear warhead without the use (insertion) of a controlled numerical code, thus reducing the probability of an unauthorized nuclear detonation."[20]

DOE b(3)

DOE b(3)

DOE b(3)

(U) Today, the commanders of the unified and specified commands to which nuclear weapons are allocated are responsible to the President and the Secretary of Defense to:

> (U) "establish and supervise the policies, practices and responsibilities for the storage, safety, security, custodial control, deployment, and utilization of nuclear weapons."[23]

(U) Explicit reference to PAL in relation to the theater commander's custodial mission and in particular to his weapon security responsibilities does not appear in either Ref 23 or 24.

DOE b(3)

1.3.2.4 Related Documents (U)

(C) A letter from James P. Wade, Jr., Chairman of the Military Liaison Committee, to Duane Sewell, Assistant Secretary for Defense Programs, dated 18 April 1980, accompanied the current version of the PAL General Characteristics. This letter (Appendix C) comments on the role and function of PAL. The function of PAL as delay is emphasized. However, a broader role is presented for PAL than that envisioned in today's theater implementation.

DOE b(3)

the JCS. This requirement states that all TNWs deployed to foreign soil will be PAL-equipped.

Responsibility for implementing and operating the PAL code-management system is delegated to the theater CINC. DOE b(3)

- (U) PAL must be compatible with all other weapon system requirements.
- (C) The function of PAL devices was historically recognized as delaying for a period of time, after unauthorized access to a weapon has been gained, the unauthorized detonation of that weapon. This is also the recognized function of PAL today.
- (C) The operational context in which today's theater PAL systems function suggests that PAL is one measure which protects against unauthorized use by US or Allied forces. Additionally, some benefit (delay) would be provided if outsiders (terrorists or host nation forces) were to gain access to a weapon. However, no explicit and agreed-upon definition of the threat against which PAL is intended to provide protection currently exists. Such definition would be useful in assessing the performance of todays PAL system.

2. PAL Systems Today (U)

(U) A third relevant document[28] from the office of the Assistant to the Secretary of Defense for Atomic Energy summarizes measures currently being implemented to upgrade the safety and security of nuclear weapons. Among the issues discussed in this document are

- Improvements in physical security to minimize the likelihood of loss of control of a nuclear weapon
- Stockpile improvement programs that address, among other things, modernization of the PAL protection in some of the older systems expected to remain in stockpile
- Modernization of DoD policy directives to clarify standards and criteria for positive control measures for nuclear weapon systems.

1.3.3 Summary of Objectives and Requirements (U)

(U) A review of historical and current documents and examination of today's theater PAL systems lead to the following conclusions:

- (S) The requirement for PAL originated at the Presidential level and is promulgated through

2.1.1 PAL Devices (U)

(U) Table 1 shows current and planned weapons by PAL device type. These devices are discussed below.

Note: ( ) indicates weapon in development

2.1.1.1 Combination Locks (U)

(U) Most weapons—bombs delivered by aircraft, missiles, and shells—experience a unique environment during deployment, e.g., spin, acceleration, pressure change. To provide the desired preflight handling safety, a family of ESDs evolved which close critical electrical arming lines only after the weapon experiences the desired environmental signature. In the case of ADMs, manually set in place and fired by either command or timer, there was no launch, drop, or fire environment which could be sensed by an ESD. Installation of 3-digit combination locks provided an additional safety step in the prefiring sequence (Figure 2). The 3-digit locks were redesigned by the AEC to provide 5 digits to be compatible with a 4-digit split-knowledge code management system. The Army also developed combination locks for use on several weapon systems. About half of the European stockpile is still equipped with combination locks. They are used on the W31 Nike Hercules, W45 MADM, W54 SADM, M422 (W33/8-in. AFAP) and M454 (W48/155-mm AFAP).

(U) The M422 uses an Army lock. The M83 atomic weapon locking device screws into the projectile's base; one part (the locking tube and desiccant assembly) occupies the volume into which the breech-lock-fuze assembly must be installed before firing. The M454 uses an Army lock. The M76 atomic weapon locking device screws onto the projectile's nose, replacing the projectile's fuze (Figure 3). The W31 warhead for the Nike Hercules missile uses an Army lock. The M77 atomic weapon locking device fits onto the safing plug of the Adaption Kit (AK) (Figures 4 and 5). The W31 warhead for the Honest John missile uses an Army lock. The M81 atomic weapon locking device fits onto the safing plug of the AK (Figures 6 and 7).

(U) The W45-3 warhead for the MADM uses an AEC lock. The MC1885 padlock is installed on the warhead's J1 connector and prevents input of electrical signals to warhead circuits (Figure 8). The B54 warhead for the SADM also uses an AEC lock. The MC1948 lock-secured cover includes an MC1827 padlock (Figure 9). The cover denies unauthorized access to the arming and fuzing components.

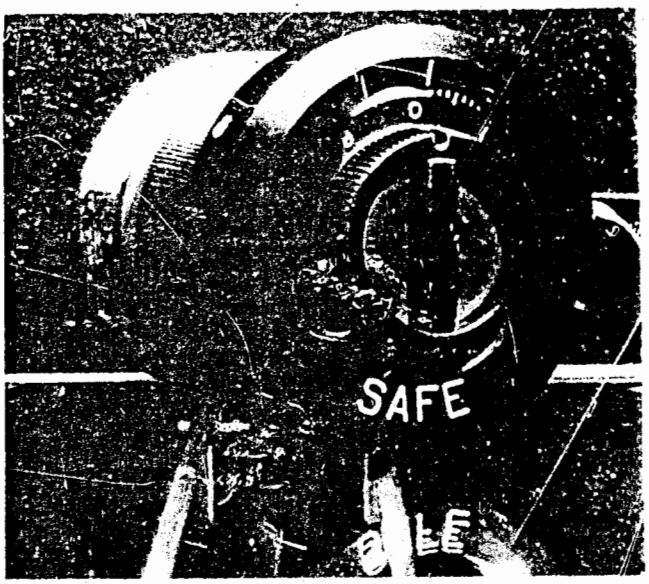
Figure 4. M77 Atomic Weapon Locking Device (U)



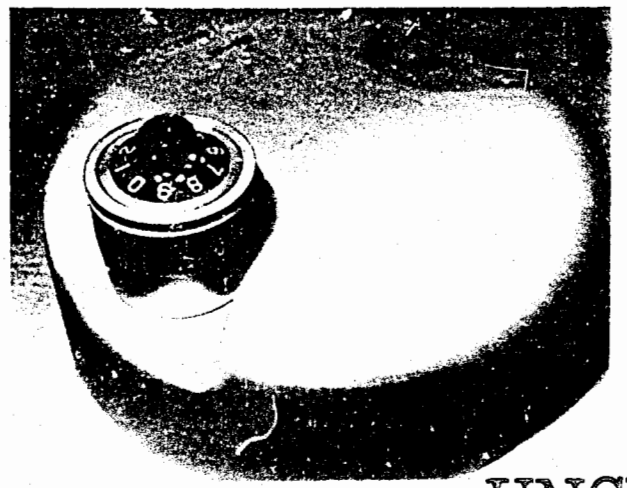


Figure 7. Mod Atomic Weapon Locking Device (U)

a

b

Figure 8. MC1552 Padlock (U)

(U) As originally fielded, the CAT B PAL system (Figure 11) included two electromechanical coded switches (MC1707s) in each weapon, two ground controllers (T1508 Decoder and T1509 Recoder), two controller testers (T1520 and T1521 for the Decoder and Recoder, respectively), three aircraft controllers (DCU117/A and DCU121/A, combined AMAC and PAL, and the DCU116/A PAL only), and a power source (T436 Battery). CAT B was installed only in bombs which have Air Force and Navy applications (primarily Air Force).

(U) The subsequent fielding of CAT D and F PAL has resulted in requirements for back-compatibility of CAT B with newer control equipment developed for CAT D and F. Today, CAT B PAL can be operated by the T1535 Ground Decoder; the T1536, T1555, and T1563 Recoders; the T1539 Verifier; and the DCU192, 196, 201, 218, 238, and 239, as well as those controllers listed earlier.

(U) The MC1707 (Figure 12) occupies a retangular volume of ~18 cu in., weighs ~ 2.2 lbs, and takes ~30 s to operate. It is used today in the B28-RE, B43-2, B57-2, and B61-0 bombs. Several improvements were made in the MC1707 design to overcome problems with the CAT A PAL system. The CAT B system requires 5 wires to recode, control, and monitor a weapon instead of the 14 required by CAT A. In addition, to minimize the impact on aircraft wiring, only three wires are required to control any number of switches operating in parallel, plus one wire per weapon to monitor the weapon's lock/unlock status.

(U) The CAT B system provides recode and code check capability for the stored codes without transferring the output contacts from the locked to the unlocked condition, or vice versa. Also, CAT B requires use of the stored code for a lock operation. This avoids possible accidental relock upon insertion of a wrong code after unlock. Finally, the recoders provide automated sequences of old code insertion, new code insertion, and code check operations.

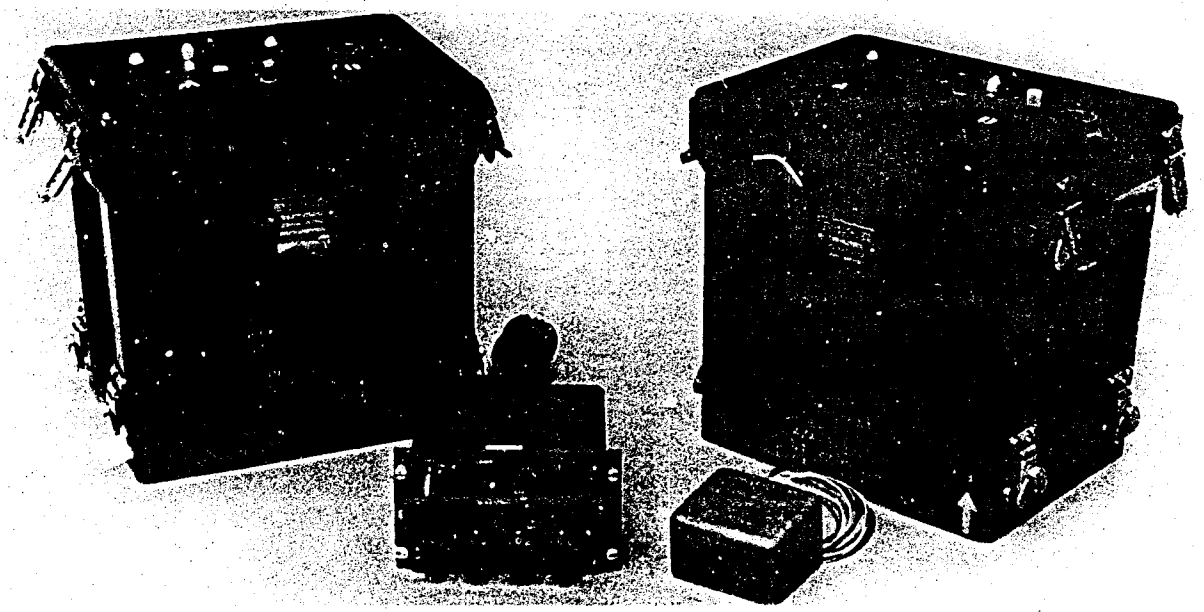

Figure 11. CAT B PAL System (U)

Figure 12. MC1707 (U)

2.1.1.4 Multiple-Code Coded Switch (U)

(C) A desire for selective unlocking through the use of multiple codes led to the concept of a multiple-code coded switch (MCCS). In May 1971, a requirement to incorporate an MCCS into the W74 was approved as Amendment 3 to the 155 mm Howitzer Projectile Military Characteristics. Miniaturization was essential because of the small volumes of the newer systems (W74 155-mm and W75 8-in. projectiles).

The MCCS design combined some new PAL-associated features with existing and still-required characteristics. They were:

- No power required for memory storage
- Compatible with aircraft cockpit control
- Knowledge of old code required for recode

DoE b(3)

(C) The MCCS was developed as two separate items, the MC2764, ~17 cu in. (Figure 13), and the MC2907, ~1.5 cu in. (Figure 14). Both devices provide similar capabilities and are compatible with the same control equipment. MC2764 was developed on an accelerated basis to be available on an early timescale and is used in the W70-1 Lance and B61-2 CAT D applications. MC2907, with more difficult packaging concepts but employing basically the same hybrid microcircuit technology, was developed on longer timescales and is presently used or planned in the B28-0, and -1, B61-5, -6, -7, and -8, W79, W80, W81, and B83 CAT D applications.

DOE b(3)

2.1.1.5 Multiple Code Coded Security Switch (U)

(C) The MC3641 MCCSS, sometimes called GLCM Security Unit (GSU), is ~4.36 cu in. in volume and will be used with the GLCM to provide a 12-digit

DoE b(3)

code capability (Figure 15). It will permit numerical assurance against bypass in accordance with DOD Directive 5200.16 in several scenarios associated with unauthorized launch.

DOE b(3) ID or serial number can be obtained upon query. Because the MCCSS is microprocessor-controlled and because of the different code length, a byte-oriented data format between the controllers and the MCCSS was chosen. The MCCSS will require new control equipment for recode and control. The T1563 Automated PAL Controller is being fielded on a timescale compatible with the GLCM for recode and APS maintenance control.

DOE b(3)

2.1.2 Control Equipment (U)

(U) PAL control equipment has become very diverse and, in some cases, quite specialized. In most cases, control equipment was designed and developed by the DOE with DOE funds in response to DOD needs. Production has usually been managed by DOE and funded by DOD. There have been a few recent examples of specialized application (PII and GLCM) for which DOE specifications were provided, and design, development, and production were funded and managed by DOD. The categories of PAL control equipment are:

Recoders (Recode and Code Check)
Verifiers (Code Check)
Ground Decoders (Unlock and Lock Control)
Cockpit Decoders
Controller Testers

(U) The listing of Table 2 is believed to be complete. Newer controllers are back-compatible with earlier categories of PAL, except for CAT A. In most cases, older controllers have remained operational, particularly the decoders, because they are usually available and meet original operational requirements. Individual ground control items are discussed below.

Table 2. DOE-Supplied PAL Ground Controllers (U)

* Estimates
** No Longer Used

2.1.2.1 T1500 Category A Decoder (U)

(U) The T1500 controller is used to unlock and lock the MC1541 coded switches (Figure 16). It drives the MC1541 motor to a position consistent with the code selected and set in the T1500, provides energy to open or close the output switches, and monitors the status of the MC1541. The T1500 weighs ~40 lbs with the T436 Power Supply attached. It controls two MC1541s simultaneously from the two independent channels and indicates when at least one of the MC1541 output switch sets closes.

2.1.2.2 T1501 Category A Recorder (U)

(U) The T1501 is similar to the T1500 decoder but has a code change capability (Figure 17). It selectively operates only one MC1541 coded switch at a time, first setting in the correct old code, then unlocking and preparing the switch for insertion of a new code. The new code is then set into the T1501 and the operation repeated, inserting the desired new code. An incorrect code must then be entered to relock the coded switch. This does not occur in an automated sequence but is done as separate operations for each of two coded switches in the weapon.

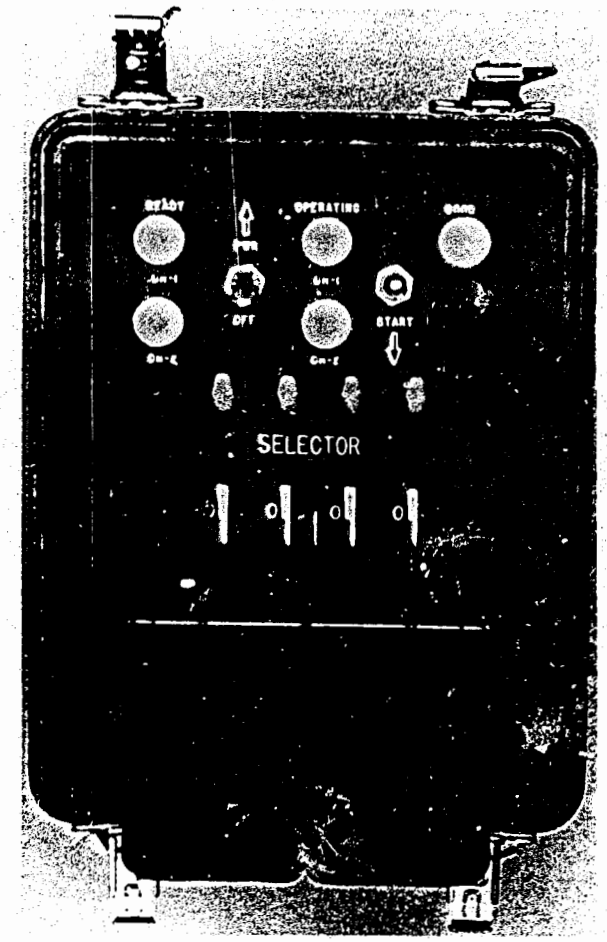

Figure 16. T1500 CAT A PAL Controller (U)

Figure 17. T1501 CAT A PAL Recoder (U)

2.1.2.10 T1536 Air Force/Navy Recoder for PAL Categories B, D, and F (U)

(U) The T1536 (Figure 26) is a controller used by the Air Force and Navy to recode and code-check the coded switch in a weapon; it can also be used to check the lock/unlock status of the weapon.

(U) A single-code or all-codes recode operation will always leave the weapon coded switch in the locked state. A code-check operation will not change the locked/unlocked status of the coded switch. The T1536 automatically recognizes a coded switch system as either single code (CAT B) or multiple code (CAT D/F) and furnishes the appropriate signals to the coded switch in a weapon. Power is supplied to the T1536 through a CT1478 cable from the T436B Power Supply. All of the necessary codes (one old and six new PAL codes) plus one new maintenance code are manually set into the T1536. After the codes are set, recoding or code-check is a single-cycle, semiautomatic operation.

2.1.2.11 T1539 Army/Air Force/Navy/ Code Verifier for PAL Categories B, C, D, and F (U)

(U) The T1539 is a controller used in the field by the Army, Air Force, and Navy to check code values in the coded switch in CAT B, B', C, D, and F PAL weapons; it may also be used to check the locked/unlocked status of the weapon. The T1539 recognizes a coded switch system as either single code (CAT B/B'/C) or multiple code (CAT D/F) and furnishes the appropriate address to the coded switch in the weapon. Power is supplied to the T1539 through a CT1478 cable from a T436B Power Supply.

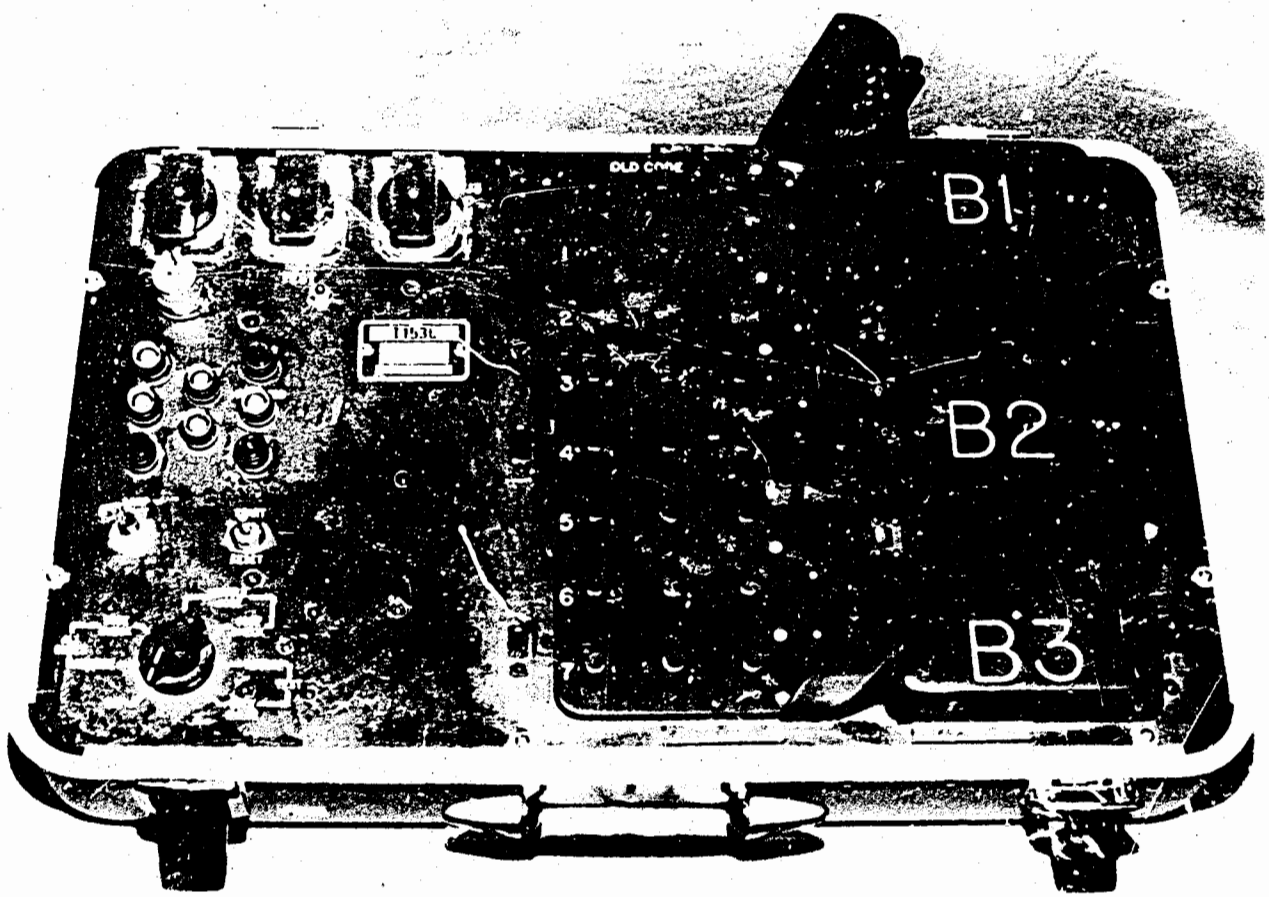

Figure 26. T1536 Air Force Recoder for CAT B, D, and F PALs (U)

2.1.2.12 T1547 Army/Air Force/Navy Adapter for Category F PAL (U)

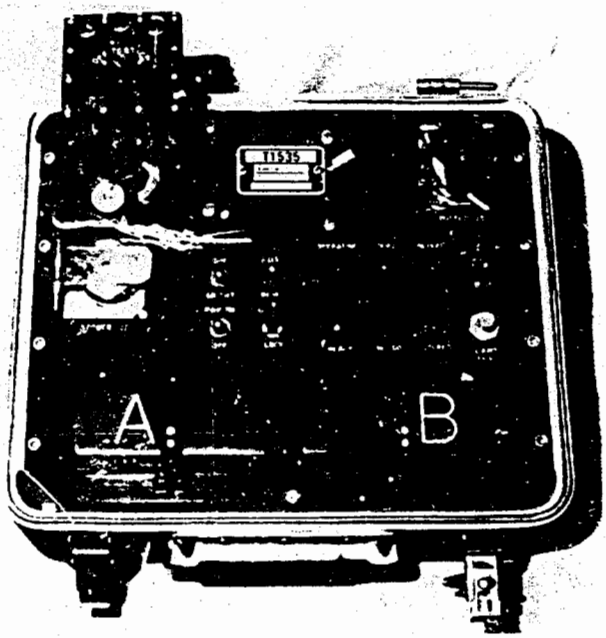

Figure 28. T1535 Decoder with T1547 Attached (U)

2.1.2.13 T1549A Air Force/Navy Programmer for PAL Categories B, D, and F (U)

(U) The T1549A performs two functions when connected to the new controllers. It performs a duration and amplitude check on the aircraft and ground controller output data and power circuits for CAT D and F PAL systems; it also functions as a coded switch simulator for CAT B, D, and F PAL systems for training in decoding operations with the T1549A, the aircraft, and T1535 Ground Decoder.

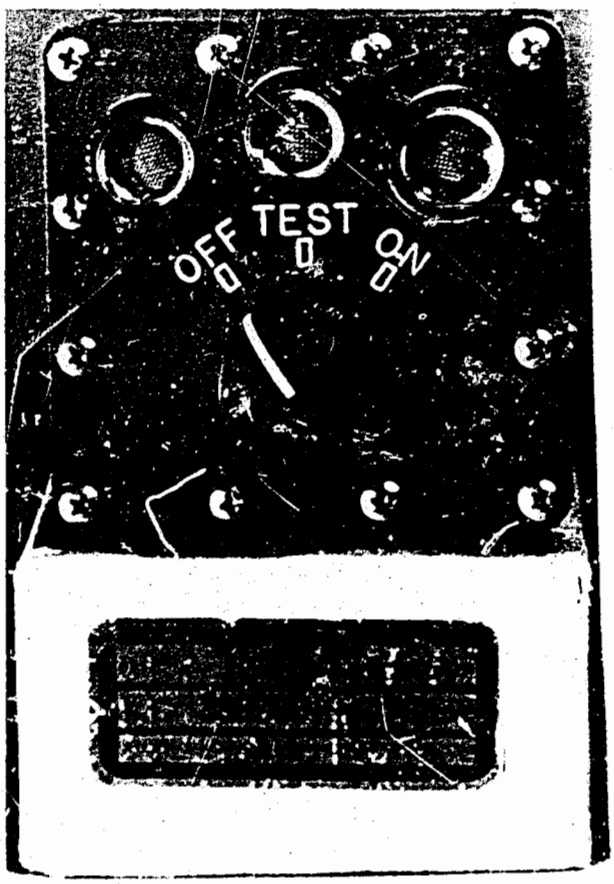

Figure 27. T1547 CAT F PAL Adapter (U)

(U) The T1549A furnishes feedback to the decoder which allows the operator to determine that an acceptable or unacceptable response has occurred. For training operations, storage of seven different codes is provided; any of these codes furnishes "off" and/or lock and unlock indications, as appropriate. The T1549A contains no control switches or monitor lamps. These responses are furnished by the controller to which the T1549A is interfaced.

Three cables are required for use with the T1549A. The CT1504 connects the T1535 Ground Decoder to the T1549A Programmer. This cable is currently used with all Air Force/Navy ground controllers. In addition, the CT1507 cable connects the T1549A to the pylon of the F4C, D, or E, and the CT1510 connects the T1549A to the F-111E aircraft pylon. No external or auxiliary power cable is required because the T1549A is powered by the ground decoder or aircraft safe power.

2.1.2.14 T1554 Army/Navy Decoder for PAL Categories D and F (U)

(U) The T1554 (Figure 29) is a controller used by the Army to lock or unlock the coded switch or to check the locked/unlocked status of the weapon. It is very similar to the T1533 except that it cannot be used to operate the single code CAT C System.

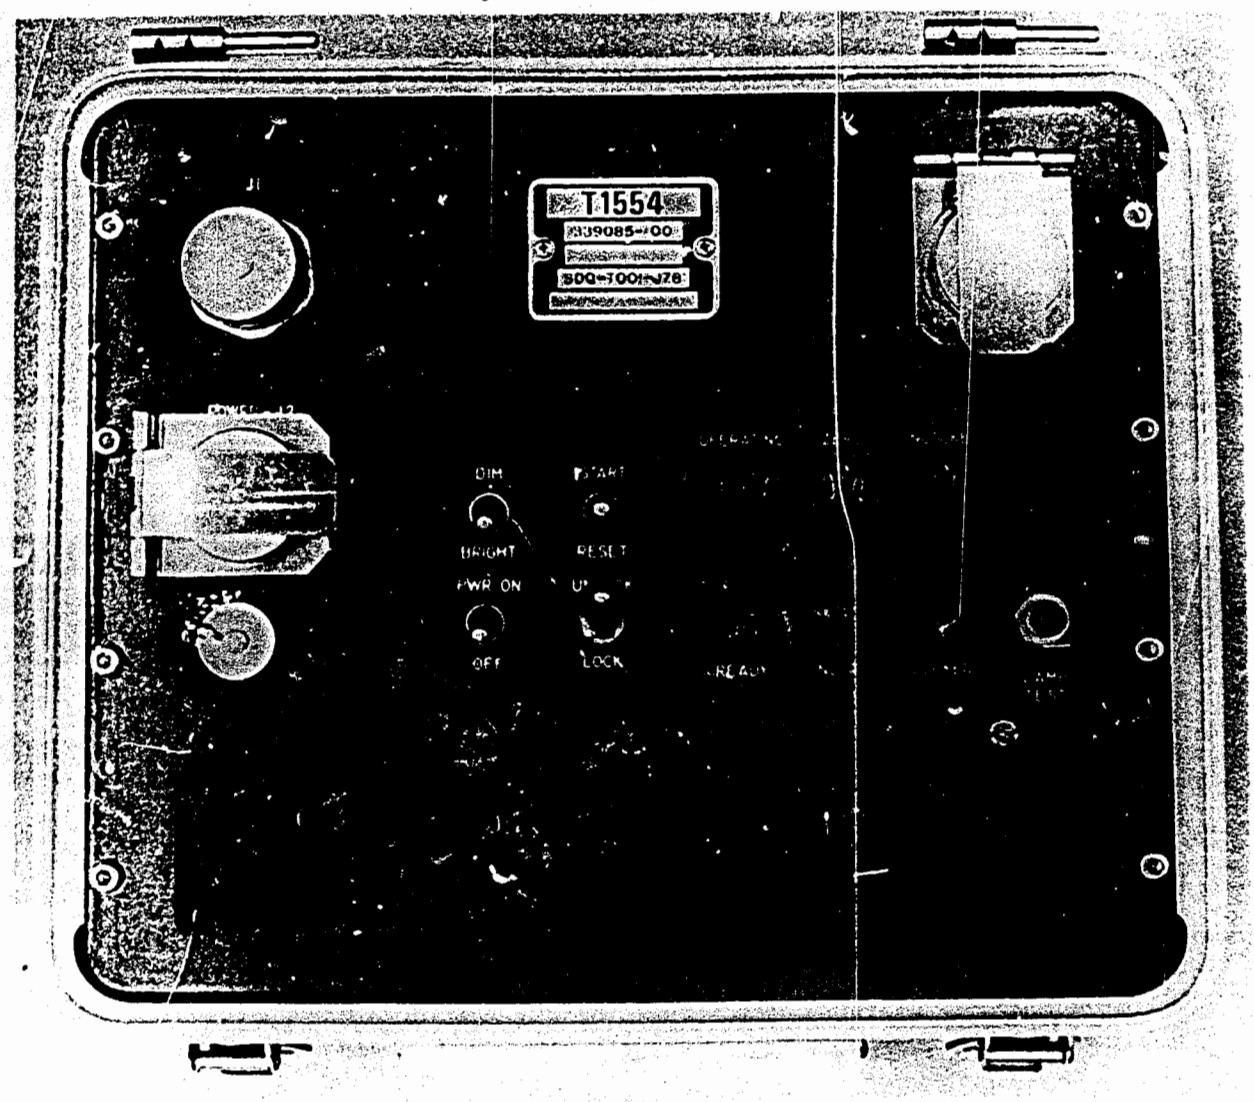

Figure 29. T1554 Army Decoder for CAT D and F PALs (U)

(U) The T1554 is not capable of a recoding operation. Power is supplied through the CT1478 cable from a T436B Power Supply or from a tactical vehicle's battery. If tactical vehicle power is used, the T1554 will operate with the vehicle either off or operating. The decoder was originally purchased to support the W79 system.

2.1.2.15 T1555 Army/Air Force/Navy Recoder/Verifier for PAL Categories B, C, D, and F (U)

(U) The T1555 (Figure 30) is a controller that can be used by all services as either a recoder or a code verifier. The T1555 by itself is a controller used in the field to verify the code values in the coded switch in CAT B, C, D, and F weapons and may also be used to check the locked/unlocked status of the weapon. With the T1558 plug adapter installed, the T1555 is a recoder used in the field to recode and code-check the coded switch in a weapon; it may also be used to check the lock/unlock status of the weapon. A single-code or all-codes recode operation will always leave the weapon coded switch in the locked state. A code-check operation will not change the locked/unlocked status of the coded switch. The T1555 automatically recognizes a coded switch system as either single code or multiple code and furnishes the appropriate signals to the coded switch in a weapon. Power is supplied to the T1555 through a CT1478 cable from the T436B Power Supply. All of the necessary codes (one old and six new PAL codes) plus one new maintenance code are manually set into the T1555. After the codes are set, recoding or code-check is a single-cycle, semiautomatic operation.

2.2.1.6.2 PAL Release Procedures in the European Theater (U)

(U) Weapon Deployment in the European Theater—In general terms, the mission of all US and Allied forces and weapons in Europe is to

> (U) "deter war by their presence and the credibility of their probable use and effectiveness in any conflict situation between Warsaw Pact and NATO forces"[30]

(U) To this end, US nuclear weapons have been deployed to locations in EUCOM for possible use by US and NATO forces. This deployment is made possible through bilateral programs of cooperation negotiated between the host NATO countries and the US.

[redacted]

DOE b(3)

(U) Weapon Employment in the European Theater—(U) In keeping with the NATO nuclear strategy of flexible response, planning for nuclear weapon employment in a European conflict encompasses options which range from massive response to very selective employment of a few weapons.

DOE b(3)

DOE b(3)

(U) As weapon and control hardware evolve, improvements and changes are expected to occur. Because a mix of old and new systems is likely to remain, it may not be possible to utilize some capabilities fully. Study of goals and requirements is warranted to give direction to acquisition of future systems.

4. PAL Advanced Development (U)

(U) Today's PAL hardware elements and code management system were described in Section 2. New concepts in both hardware and code management are now in various stages of development. These concepts are summarized in this section.

4.1 New PAL Weapon Systems (U)

(U) The W84 warhead for the GLCM, which is scheduled for deployment in late 1983, is the most recent PAL weapon system described in Section 2. Several other new systems are in various stages of development or production.

DOE
b(3)

(U) The W79 8-in. AFAP preceded the W84, entering Phase 6 production in September 1981. Ultimately the W79 will replace the W33 8-in. projectile in stockpile. However, a date for overseas deployment is uncertain at this time. The W79 is equipped with the MC2907 MCCS that provides CAT D PAL protection.

(C) The W85 PII warhead begins Phase 6 production in May 1983. Eventually, the improved PII system will replace many PIs presently deployed to NATO. The W85 is basically a B61-4, CAT F warhead adapted to the warhead section of the PII missile. As such, it is equipped with an MC2907A MCCS.

(C) The W82 155-mm AFAP that will replace the W48 projectile is presently scheduled to enter Phase 6 production in June 1986. No deployment date has been announced. The W82 will be equipped with the MC3764 CAP (Section 4.2). The CAP will provide the same multiple code population and limited-try features as the MCCS, but the W82 will not be maintained in a disenabled state by interrupting warhead circuitry. Instead, the CAP will be located outside the weapon in a Use Denial Lock (UDL). The UDL (Figure 44) is a device which fastens to the nose of the projectile, preventing installation of the fuze. Unlocking the CAP allows removal of the UDL. An Integrated Control Unit (ICU) in the shipping container of each round will provide unlock and relock control of the UDL (Figure 45).

(U) A factory-rebuild program is currently under way to upgrade early versions of the B61. The B61-6 will result from retrofitting the B61-0 with enhanced safety features and the MC2907 CAT D PAL. First Phase 6 production is scheduled for October 1985. The B61-8 represents a safety upgrade of the B61-2 and B61-5. The B61-8 will have an MC2907 CAT D PAL and is scheduled for initial Phase 6 production in January 1988.

(U) Four strategic systems with PAL are planned for the stockpile. Two of these are modifications of existing systems. The B28 (Mods 0 and 1) will be field retrofitted (beginning April 1983); B61-1 will be factory rebuilt (Phase 6 begins September 1985) into the B61-7. Present plans call for an MC2907 CAT D PAL in both systems. Two new strategic systems, the W80-1 warhead for the Air-Launched Cruise Missile (ALCM) (Phase 6 production began February 1982) and the B83 modern strategic bomb (Phase 6 production is scheduled to begin September 1983), also will be equipped with the MC2907 CAT D PAL.

(U) Two new PAL-equipped Navy systems are currently planned. Both the W80-0 warhead for the Tomahawk Sea-Launched Cruise Missile (SLCM) (Phase 6 production is to begin April 1984) and the W81 warhead for the SM-2 fleet air defense missile (Phase 6 production to begin November 1986) will have CAT D PAL (MC2907 or MC3764).

(U) A stockpile projection[31] (Figure 46) shows the planned distribution of PAL-equipped weapons (weapons with no PAL are not shown) through FY 1992. This projection reflects the planned production of weapons equipped with modern CAT D and F PAL devices.

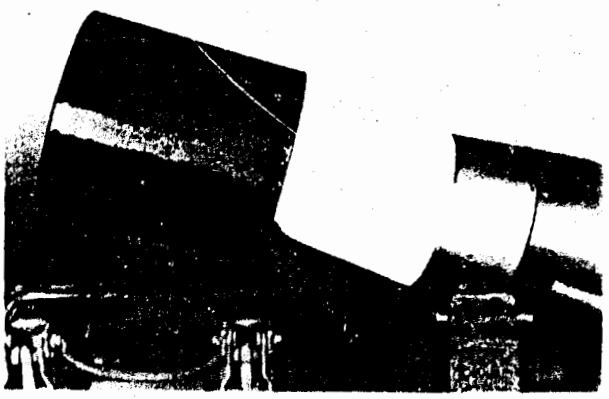

Figure 44. Use Denial Lock (U)

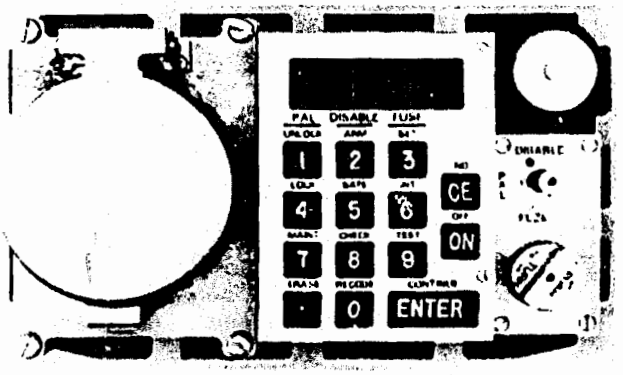

Figure 45. Integrated Control Unit (U)

(U) The HCP (Figure 47) is built around an HP 1000 computer. The system includes a printer, CRT display screen, keyboard, tape and disc storage units, and a cryptographic system. HCP operation is depicted in Figure 48. It has a number of functions. First, it provides access, under two-man control, to encrypted code information from the source data module generated by NSA. In addition, it contains a weapon data base that may be periodically updated.

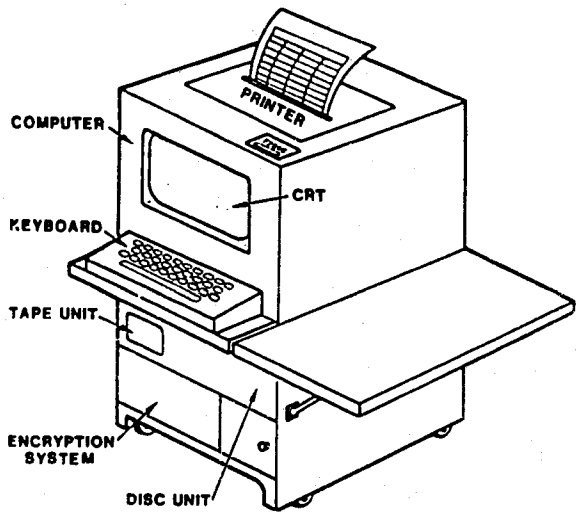

Figure 47. T1565 HQ Code Processor (U)

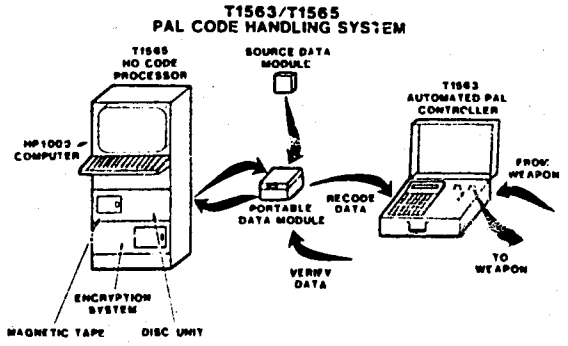

Figure 48. T1563/T1565 PAL Code Handling System (U)

This data base would include, for example, the theater weapon inventory information: mark and mod, serial number, and location of weapons in theater. Utility programs will be available for correlating the data base information with the weapon code information to aid in the construction of theater code plans. Given a theater code plan, the HCP will be able to generate the appropriate portable data modules for use by APCs during recode operations. The HCP will also be capable of reading monitor modules generated by the APC during recode. This may eliminate the need for on-site recode verification by the PMCT in cases where recode can be done with the APC.

June 6, 1962

NATIONAL SECURITY ACTION MEMORANDUM NO. 160

TO: The Secretary of State
The Secretary of Defense
The Chairman, Atomic Energy Commission
The Director, Bureau of the Budget

SUBJECT: Permissive Links for Nuclear Weapons in NATO

1. After an examination of the problem of installing permissive links in nuclear weapons dispersed in NATO commands, I have decided we should now make the commitment to procure appropriate devices for all nuclear weapons, now dispersed and to be dispersed to NATO commands, for both non-U.S. and U.S. forces. (See attached memorandum to me from Dr. Wiesner dated May 29. This decision corresponds to Alternative 5 of that memorandum.)

2. This will require a supplementary appropriation for the Atomic Energy Commission budget. The Secretary of Defense, the Chairman, Atomic Energy Commission, and the Director, Bureau of the Budget will work out the details of the budget presentation.

3. At the earliest feasible time, the Secretary of Defense will submit for my approval a schedule for installation of these devices in NATO weapons. In making this schedule, the Secretary should consult with the Secretary of State on the political problems arising from the existence of weapons assigned to U.S. forces and weapons assigned to our Allies.

4. The Chairman, Atomic Energy Commission, in consultation with the Secretary of Defense, will carry out a research program on an urgent basis directed toward an examination of the feasibility and desirability of more advanced permissive link devices with a wider range of capabilities.

/s/ John F. Kennedy

UNCLASSIFIED

APPENDIX A

NSAM-160 and Wiesner Memorandum
Original Document Secret

MEMORANDUM FOR

THE PRESIDENT

At your request, I have reviewed, in consultation with the AEC and the DOD, the technical and cost aspects of equipping nuclear weapons dispersed overseas with permissive link hardware. The object of this review was to establish the program options that were technically available to implement such a program as rapidly as possible, and to determine the amount of supplemental funds that would have to be requested in the AEC FY '63 Budget to accomplish these options.

A decision on this problem involves the following basic policy issues which, while not technical in themselves, are affected by the availability of equipment and the program timing and cost:

(1) Should a permissive link be incorporated at this time in all dispersed nuclear weapons or just in those critical weapon systems with quick reaction, high yield and long range (e.g., Jupiter missiles and quick reaction aircraft)?

(2) Should a permissive link be incorporated at this time in all weapons dispersed to NATO (U.S. as well as non-U.S.) or just to non-U.S. weapons?

(3) Should a permissive link be incorporated at this time in weapons committed to NATO but based in the U.K. as well as weapons based on the European Continent?

These policy issues raised the more basic question as to what objective one is attempting to accomplish by incorporating a permissive link. A permissive link can attempt to meet any of the following objectives, each of which imposes increasingly difficult technical problems:

purpose of this review, I have not attempted to meet a specific objective but rather have analyzed the operational value of the best available equipment and attempted to determine how rapidly it could be incorporated in dispersed nuclear weapons.

While the permissive link equipment presently recommended by the AEC leaves something to be desired and can clearly be much improved with time, I believe that this equipment can be used as the basis for a crash program since development quality hardware exists and initial production and installation could begin in the immediate future.

Specifically the AEC recommends that, if a permissive link program is undertaken on a crash basis, bombs for aircraft and warheads for longer range missiles be equipped with an electro-mechanical lock which would have to receive a prearm numerical code in order to make the weapon operable. In the case of certain bombs which cannot be easily retrofitted with this equipment, as an interim measure pending the development of improved compatible permissive link hardware, mechanical combination locks would be installed to cover a socket into which an arming plug must be inserted. In the case of those bombs as well as short range missiles, such as Honest John and Mike Hercules, and the 8-inch shell, the arming plugs would be stored in self-destruct safes. The proposed program does not include specific hardware for the Davy Crockett missile which presents a particularly difficult problem because of its small size and possible forward deployment.

The numbers which would operate both the electro-mechanical and the combination lock could be held at any echelon or command. If circumstances required, the combination could be held by the U.S. custodial officer himself. This procedure could therefore give the weapons the same state of readiness that they now possess.

In evaluating the utility of this equipment, it must be recognized that it is simply intended to buy time. A specialist with proper equipment might be able to crack the electro-mechanical lock in a few hours time. If he were able to circumvent the self-destruct feature of a safe, a skilled locksmith could open a combination lock relatively quickly. In any event, it would also be possible for skilled technicians familiar with weapons to make these weapons operate in a period of from several hours to weeks, depending on the extent of thier knowledge, by opening the weapons and bypassing the electric circuits. Despite the limitations of this equipment, I believe it would give further (and probably decisive) protection against individual psychotics and would certainly cover unauthorized use by military forces holding the weapons during periods of high tension or military combat. While it would not assure that the weapons could not be used if they were forceably seized by an organized group or a foreign power with technically capable individuals, it would provide in the case of the more important weapon systems equipped with electro-mechanical lock a period of time, varying from hours to days, in which decisions could be made as to what our proper response to the seizure should be. The question of the legal and political requirements of control were beyond the scope of my review.

The question has been raised whether the installation of this development quality hardware on a crash basis might reduce the reliability of the nuclear weapons. However, in view of the simple nature of this equipment and the method of installation, I believe that it is now generally agreed that it would not reduce the inherent reliability of the weapons. The weapons would, of course, not be operable if the combination number were not received from a higher headquarters. This is a communication and management problem, which can be very simple or a very complex, depending on the level of command at which the combination number is held and the degree of control maintained through coding procedures or the use of different combination numbers for different weapons. In its simplest form, it should be possible to handle this procedure wherever a "go code" can be transmitted which is presently a requirement if any control is to exist. In any event, I wish to emphasize that, if circumstances demand, a decision can be made to release the combination number to the U.S. custodian with the field unit and thereby revert to the state of readiness and control that exists today.

At my request, the AEC has estimated the cost and time for completion of the following five alternative programs, which I believe represent the full range of possible application of the permissive link on a crash basis to nuclear weapons dispersed to the European Theater:

The estimated completion date, total cost, and FY '63 for each of these programs is as follows:

Alternative	Estimated Date Completed Installation	Total Cost ($ Millions)	FY '63 Cost ($ Millions)
I	June 1963	3.2	3.2
II	Oct. 1963	11.3	10.6
III	Dec. 1963	13.6	11.7
IV	Mar. 1964	18.6	13.8
V	Aug. 1964	26.9	14.0

A supplemental to the AEC FY '63 Budget would call for obligation of the total cost of the program but expenditure of only the FY '63 cost of the program.

On the basis of this review, I have concluded that it is technically possible to equip on a crash basis all nuclear-weapons dispersed to the European Theater with reasonably effective permissive link equipment at relatively small cost. Therefore, the decision as to the extent to which permissive link equipment should in fact be incorporated in dispersed weapons can be made solely in terms of broad policy considerations as to the desired objective.

Whatever decision is made on the crash program to install permissive link equipment on dispersed nuclear weapons equipment, I would recommend that a vigorous program be undertaken to develop an improved electronic lock which would be incorporated directly in the electronic package associated with all future weapons so that the option of a permissive link would always exist. This program should also include work to develop improved devices to retrofit the bombs and medium range missiles which were equipped with combination locks only as an interim measure in the above crash program. I would also recommend that there be an agressive research program to develop more advanced concepts of the permissive link including mechanics to assure the self-destruction of a weapon if efforts were made to by-pass the permissive link. It is my understanding that the AEC has funds available to cover the R&D necessary for these advanced programs.

Jerome B. Wiesner

APPENDIX B

General Characteristics for PAL Devices
Original Document Secret

Item I

GENERAL CHARACTERISTICS FOR PREMISSIVE DEVICES
FOR USE WITH NUCLEAR WEAPONS (U)

General Characteristics
Approved by the OSD:
13 September 1962

1. Purpose. These General Characteristics define an arming control device for use with designated nuclear weapons which is intended to provide some additional physical means for preventing unauthorized use of nuclear weapons.

2. General Characteristics. The device shall conform to the general characteristics and provide the capabilities listed below:

a. The device shall be capable of repeated enabling, disenabling, and recoding. Further, the device shall be capable of being maintained in either the enabled or disenabled mode.

b. When the device is enabled, a positive indication of enabled condition shall be provided. It is highly desirable that this indication provide no usable information to an unauthorized operator.

c. The time required for authorized enabling of the device shall not add to the weapon system reaction time under any readiness condition. Capability for inflight operation of this device is required for certain aircraft applications.

DOE
b(3)

e. The device and associated equipment shall be designed so that inspection or disassembly of the weapon will not disclose the combination or code.

f. The combination or code shall be transmitable by all standard communications means, and shall be capable of being changed rapidly and accurately by persons having the appropriate equipment and the old combination or code.

g. The device shall be so located and shall function in such a manner that it will permit performance of the required weapon maintenance, retrofit, and test operation throughout the stockpile-to-target sequence, without enabling the device.

h. The device and associated equipment shall be of such quality as not to decrease significantly the weapon reliability.

i. The device and its associated equipment shall be designed so as to permit installation and use of the device in bombs or warheads without degrading weapon safety.

j. The device installed in the weapon itself should not degrade the delivery capability or alter the ballistics of the weapon system.

k. Meters, dials, and switches on device components which are used in the open without blackout protection shall be illuminated in such a manner that blackout will not be violated.

l. The device and its related equipment shall withstand, without functional impairment or reduction of operational reliability, the environmental criteria specified in the applicable stockpile-to-target sequence of authorized weapon applications and in assoicated environmental specifications.

5. Inspection & Maintenance.

a. The system shall be designed so that inspection or disassembly of any component external to the warhead will not disclose the codes.

b. The permissive action link shall be so located and the system shall function in such a manner that it will permit perormance of the required warhead maintenance, retrofit (including internal and external components exclusive of the permissive action link system), and test operations throughout the STS without changing the mode of the device.

c. The system shall be capable of having maintenance performed on it in either the enabled (unlocked) or disenabled (locked) mode.

d. The operational storage life of that portion of the system installed in the warhead shall be no less than that of other warhead components.

6. Control Equipment.

a. Control equipment with the exception of decoders installed in aircraft shall be designed to permit disenabling (locking) and enabling (unlocking) using the "two-man" concept, and recoding using the "two-team" concept.

b. Control equipment shall provide a positive indication of the mode of the permissive action link device. This indication should provide no information regarding the set code.

c. Decoders shall be capable of enabling (unlocking), disenabling (locking), and code checking.

d. Recoders shall be capable of recoding and code checking the system without enabling (unlocking) the device.

e. Design alternatives which combine decoders and recoders are acceptable.

7. Environmental Considerations.

a. Meters, dials, and switches on componenets which are used in the open without blackout protection shall be illuminated in such a manner that blackout will not be violated.

b. The system and its related equipment shall withstand, without functional impairment or reduction of operational reliability, the evironmental criteria specified in the applicable stockpile-to-target sequence of authorized weapon applications and in associated environmental specifications.

Item 3

GENERAL CHARACTERISTICS FOR
PERMISSIVE ACTION LINK SYSTEMS USED WITH NUCLEAR WEAPONS (U)
(Attachment to DDR&E Letter to Chmn, AEC, same subject, 31 Dec 1970.)
(Original Document Secret)

1. Purpose. To provide general characteristics for permissive action links incorporated in weapon systems to prevent an unauthorized nuclear detonation. This document is not intended to inhibit in any way development of improvements beyond the characteristics set forth.

2. General.

[redacted] DoE b(3)

b. The system shall provide for two modes, unlock and lock of the warhead by insertion of one 6-digit decimal code.

[redacted] DoE b(3)

d. The system shall not significantly degrade weapon reliability, nor shall it degrade safety, or delivery capability. The time required for unlocking the device shall not unduly add to the weapon system reaction time under any readiness condition.

3. System Operation.

a. The control equipment must provide visual indications of the status of the system. As a minimum, the equipment must indicate when (a) the number of unsuccessful unlocking attempts is zero, (b) the number of unsuccessful unlocking attempts is greater than zero but less than that required for lockout, and (c) the device is locked out.

b. The system shall be capable of recoding, unlocking or locking at any point in the STS:

(1) in the case of aircraft weapon systems, up to the time of taxi and/or aircraft launch; and enabling (unlocking) or disenabling (locking) after aircraft launch.

(2) in the case of projectiles, at any time up to the time of loading into the weapon breech.

(3) in the case of missile systems, up to the time of final prefire operations.

c. The code shall be capable of being changed rapidly and accurately by persons using the appropriate equipment. Changing of the code will be dependent upon possession of the old (existing) code.

d. At anytime prior to permanent lockout the feature which counts the number of incorrect tries shall reset to zero whenever the proper code is inserted.

e. The system shall be capable of a code check operation which will allow verification of the set code without changing the mode of the device.

4. System Compatibility and Reliability.

a. The system shall be compatible with the weapon operational concepts to include the readiness requirements stated in the STS.

b. The system will be compatible with normal logistical movement in either selected mode.

c. The system shall be electrically compatible with other weapons system circuitry. In the case of aircraft systems it will be compatible with aircraft circuitry during all phases of circuit operation, both ground and air.

d. The design of control equipment shall preclude permanent locking if a permissive action link operation is interrupted by power failure.

e. The system shall incorporate a means of determining electrically, by a T-304 or similar service continuity test equipment, whether the permissive action link device in the unlocked condition.

[redacted] UNCLASSIFIED

Item 4

GENERAL CHARACTERISTICS FOR
PERMISSIVE ACTION LINK SYSTEMS USED WITH NUCLEAR WEAPONS
(Attachment to DDR&F Letter to Chun, AEC, Same Subject, 26 July 1972)
(Original Document Secret)

1. Purpose To provide general characteristics for AEC-produced electromechanical/electronic permissive action link (PAL) systems used with nuclear weapons to prevent an unauthorized nuclear detonation. This document is not intended to inhibit in any way development of improvements beyond the characteristics set forth.

2. Nomemclature

[redacted]

DOE b(3)

3. Definitions

Permissive Action Link (PAL) – A family of devices and subsystems designed to reduce the possibility of obtaining a nuclear detonation from a nuclear warhead without the use (insertion) of a controlled numerical code, thus reducing the probability of an unauthorized nuclear detonation.

Passive Protection – Precludes operation of weapon arming circuits.

Active Protection – Senses attempts to gain unauthorized access to weapon arming circuits, with option to respond by initiating weapon disablement.

Mode – Refers to the protected condition (LOCK) or the unprotected condition (UNLOCK) of the PAL.

State – Refers to the condition of the active protection feature (OFF/TEST/ON).

Unlock Code – A preset code used to unlock the PAL.

Off Code – A preset code used to change state of OFF.

Code Check – Confirms stored code(s) in PAL without affecting weapon PAL mode.

Recode – Allows changing of stored code(s) in PAL.

Code Inhibit – Precludes a second unlock of a PAL with a given code until recode.

Limited-Try – Counts consecutive incorrect code trials and resets to zero on a correct code trial.

Temporary NO-GO – Precludes additional code trial operations without special field equipment after a number of incorrect code trials.

Permanent NO-GO – Precludes additional code trial operations with field equipment after additional incorrect code trials.

4. General Characteristics

A. Category A and Category B [redacted]

DOE b(3)

2. These systems shall provide for two modes, UNLOCK and LOCK of the PAL by insertion of one 4-digit decimal code.

[redacted] UNCLASSIFIED

B. Category B'

DOE
b(3)

3. The system shall provide for two modes, UNLOCK and LOCK of the PAL by the insertion of one 4-digit decimal code.

C. Category C – The characteristics stated above (Category B') apply with the following modifications:

1. The system shall provide for two modes, UNLOCK and LOCK of the PAL by insertion of one 6-digit decimal code.

D. Category D

DOE
b(3)

DOE
b(3)

C. (U) All Categories

(U) 1. The system shall be compatible with the weapon operational concepts to include the readiness requirements stated in the STS.

(U) 2. The system shall be compatible with normal logistical movement in any selected mode.

(U) 3. The system shall not significantly degrade weapon reliability, safety or delivery capability. The time required for unlocking the device shall not unduly add to the weapon system reaction time under any readiness condition.

(U) 4. The system shall be capable of being recoded, code checked, unlocked or locked at any point in the STS up to:

a. (U) In the case of missile systems, up to the time of final pre-fire operations.

b. (U) In the case of aircraft weapon systems, up to the time of taxi and/or aircraft launch, with unlocking or locking after aircraft launch. However, recode is not required after weapon loading on aircraft.

(U) 5. The system shall contain a Master Recode feature to allow recoding of all stored codes using any one of the old codes which has not been inhibited.

(U) 6. The system shall be capable of being recoded rapidly and accurately by persons using the appropriate equipment.

4. (U) CONTROL EQUIPMENT

A. (U) All Categories

(U) 1. The system shall be electrically and mechanically compatible with the weapon system. In the case of aircraft systems, any equipment installed in the aircraft or associated with the weapon will be compatible with aircraft circuitry during all phases of aircraft operation, both ground and air.

(U) 2. The system shall incorporate a means of determining electrically, by service continuity test equipment, whether the PAL is in the unlocked condition.

(U) 3. The control equipment must indicate when (a) the number of unsuccessful trial attempts is zero; (b) the number unsuccessful code trial attempts is greater than zero but less than that required for NO-GO; and (c) the device is NO-GO.

(U) 4. Control equipment shall be provided that will:

a. (U) Allow recoding and code checking without unlocking the PAL.

b. (U) Allow recoding any one or all unlock and off codes using one not inhibited stored code.

c. (U) Allow code checking all stored codes in one operation or code checking any one of the stored codes.

d. (U) Allow unlocking and locking the PAL.

e. (U) Allow PAL unlocking and locking operations in an aircraft to be performed by a single individual.

(U) 5. New control equipment shall minimize potential TEMPEST, tampering, and bugging vulnerabilities. DoE b(3)

5. (U) INSPECTION AND MAINTENANCE

A. (U) All Categories

(U) 1. The system shall be designed so that inspection or disassembly of any component external to the warhead will not disclose the codes.

(U) 2. The PAL system shall function in such a manner that with the active protection OFF, warhead maintenance and test operations can be performed without changing the mode of the passive protection.

6. (U) ENVIRONMENTAL CONSIDERATIONS

A. (U) All Categories

(U) 1. The system and its related equipment shall withstand, without functional impairment or reduction of operational reliability, the environmental criteria specified in the applicable weapon stockpile-to-target sequence.

(U) 2. Meters, dials, and switches on components which are used in the open without blackout protection shall be illuminated in such a manner that blackout will not be violated.

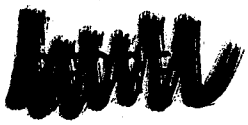
APPENDIX C

Letter from J. P. Wade, Jr., to D. C. Sewell

UNCLASSIFIED

DEPARTMENT OF DEFENSE
MILITARY LIAISON COMMITTEE
TO THE
DEPARTMENT OF ENERGY
WASHINGTON, D.C. 20301

April 18, 1980



Honorable Duane C. Sewell
Assistant Secretary for
Defense Programs
Department of Energy
Washington, D.C. 20585

Dear Mr. Sewell:

(U) Over the past several months a great deal of concern and discussion has surfaced involving the policy for non-violent disablement and what role it should play in nuclear weapon security matters. Specific controversy has centered on questions of: which weapons should have a disable capability?; what level of sophistication should be credited to the threat?; and how long should disablement render the weapon useless against this threat? Department of Defense guidance to the Department of Energy in this area has been presented in systems Military Characteristics and POG meetings, as well as in the Nuclear Weapon Development Guidance. Unfortunately, in many cases it has been less than specific or subject to interpretation in application.

(U) I would like to clarify the existing situation and toward that goal, two transmittals are enclosed. The first is a DoD statement of policy addressing the goals and current assessment needs associated with nuclear weapon disablement systems. The second is a revision of the July 1972 "General Characteristics for Permissive Action Link Systems Used with Nuclear Weapons."

DOE
b(3)

UNCLASSIFIED

(U) The paper "General Characteristics for Permissive Action Link Systems Used with Nuclear Weapons" should be viewed as the basic DoD definitions for PAL systems in acquisition of weapon systems incorporating DoE produced PALs. This paper, that supersedes the original 1972 document and amendments, will be forwarded to DNA for handling in a manner similar to weapon military characteristics, that is DNA will be responsible for publication and maintenance of an up-to-date file including amendments that may occur in the future. Consistent with our intention to work toward standardization of PAL devices and associated control equipment, only three PAL systems, Category D, E, and F are addressed in this update of the paper. Earlier PAL devices continue to remain in the stockpile: however, their acquisition cycle has been completed and therefore they have not been included in this update of the characteristics document.

Sincerely,

/s/ James P. Wade, Jr.
Chairman

APPENDIX E

JCS Pub 13, Volume II
(Excerpt From Chapter 7)

APPENDIX F

Excerpt From Amendment 3 to the Military Characteristics for a Nuclear Warhead for the 155 mm Howitzer Projectile (Approved by the MLC 27 April, 1971)

3. Control Devices

3.1 Security Container System (SCS)

An SCS, compatible with projectile and warhead designs, will be used with the M517 on an optional basis. The SCS will be developed under a program separate from the XM517 development program. The SCS shall be designed and function as specified in the SCS Characteristics attached as an Appendix.[2]

3.2. Permissive Action Link (PAL)

The PAL shall conform to the general characteristics outlined in the letter from the Director of Defense Research and Engineering to the Chairman of the Atomic Energy Commission, "General Characteristics for Permissive Action Link Systems Used with Nuclear Weapons," dated 31 December 1970.

3.2.1. The PAL control equipment shall also operate and be capable of recoding the SCS six-digit, limited-try coded switch.

3.2.2. It is desired that the control equipment be compatible with Category B, six-digit single code PAL devices.

3.2.3. The system shall provide for two modes, unlock and lock for the warhead by insertion of one six-digit decimal code. Unlock shall occur upon the insertion of any one correct code of six preset unlock codes. These unlock codes may be preset so that each is unique, or so that redundancies occur among them.

ABSTRACT

Part I gives a very simple approximate one-dimensional treatment of the terminal velocity imparted to a rigid mass by a mass of high explosive. The one-dimensional treatment is presumed to be approximately valid for the cylindrical case provided the charge thickness is small compared to the radius. The result may be expressed to a good approximation by means of the simplified formula $v = \frac{m_e}{m}\sqrt{\frac{2\,u_o}{1+m_e/m}}$, where m_e/m is the ratio (mass of explosive/mass of projectile) and u_o is the initial internal energy per unit mass of the exploded gas, assumed to be initially at uniform pressure and temperature. In Part II the mechanics of the cylinder itself is treated from simple energy arguments using the assumption of a constant yielding stress, and the result of Part I is applied to estimate the attainable collapse ratio as a function of the mass ratio of explosive and cylinder. In Part III a few new experimental data are considered. The observed collapse ratios are found to be in rough agreement with the ones calculated for RDX if one assumes an effective yielding stress of 300,000 lb/in^2. The observed mass ratios for TNT are however found to be high by as much as 50%. The discrepancy can be attributed to several things: (a) The theoretical mass ratios are only approximate and are probably too low. (b) The assumed value for the yielding stress for steel (10-20 carbon, cold drawn) may be too high and may have a lower effective value when the collapse is rapid than when it is slow. The origin of the discrepancy can be settled by measurements of the rate of collapse, or by direct measurements of heat generation. These experiments are now in progress.

THE COLLAPSE OF HOLLOW STEEL CYLINDERS BY HIGH EXPLOSIVES

I. MAXIMUM VELOCITY GIVEN TO A PROJECTILE

A correct treatment of the motion imparted to a projectile by a charge of high explosive involves a number of factors which complicate the dynamical problem of taking into account simultaneously the motions of the whole system of projectile plus exploded gas: (a) The equation of state is rather complicated because of the extreme initial pressure and density. (b) The equilibrium of combustion products presumably shifts as the hot gas expands, and (c) The detonation wave leaves the exploded gas with a residual momentum and a non-uniform pressure distribution. A very rough preliminary treatment which is of some use in correlating experimental data may be given on the following basis. (a) The motion is assumed to be one-dimensional. This should be a fair approximation for "implosions" of cylindrical or spherical shells in which the charge thickness is small compared to the radius. (b) The detonated explosive is assumed to be initially an ideal gas at uniform pressure and density. (c) The projectile is assumed to remain at rest while receiving the impulse from the explosive. Assumption (b) is presumably a fair approximation if the explosive is detonated in several directions at once, and (c) can be valid only for small ratios, m_o/m, of explosive mass to projectile mass.

On this basis we assume that only the boundary layers of the detonated explosive move, forming a discontinuous shock wave in the outside air and a discontinuous rarefaction wave moving into the exploded gas which is assumed to maintain the initial pressure p_o until the rarefaction wave

UNCLASSIFIED

APPROVED FOR PUBLIC RELEASE

APPROVED FOR PUBLIC RELEASE

UNCLASSIFIED

passes. The last assumption is not a valid one as the rarefaction wave cannot remain discontinuous, but is used only as a crude approximation to represent some kind of an average motion of the wave front. A rigorous solution for the case of an ideal gas is given by Streib in another report.

Referring to Fig. 1b, we then assume that there are three regions of constant pressure p_o, p' and the outside atmospheric pressure p_1, that rarefaction and shock waves travel with constant velocities v, v'_1, and that the boundary between expanded gas and compressed air travels with constant velocity v'. The conservation laws for mass, momentum and energy may be written down in the form:-

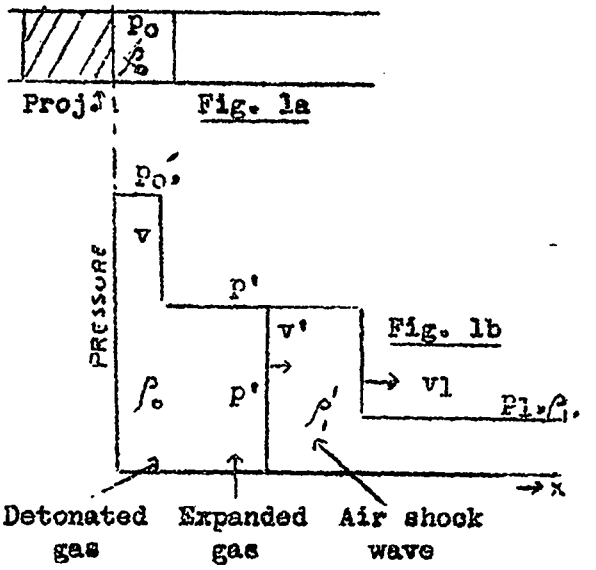

Fig. 1a

Fig. 1b

(1) $$\rho_o v = \rho'(v + v')$$

(2) $$p_o - p' = \rho_o v v'$$

(3) $$\frac{1}{\gamma - 1} p_o v = \left(\frac{1}{\gamma - 1}\frac{p'}{\rho'} + \frac{v'^2}{2}\right)\rho_o v + p'v'$$

} Rarefaction front

(4) $$\rho_1 v'_1 = \rho'_1(v_1 - v')$$

(5) $$p' - p_1 = \rho_1 v' v'_1$$

(6) $$\left[\frac{1}{\gamma - 1}\left(\frac{p'}{\rho'_1} - \frac{p_1}{\rho_1}\right) + \frac{v'^2}{2}\right]\rho_1 v'_1 = p'v' - p_1 v'_1$$

} Shock front

Here $\frac{1}{\gamma - 1}\frac{p}{\rho} = u$ is the internal energy per unit mass.

UNCLASSIFIED

APPROVED FOR PUBLIC RELEASE

APPROVED FOR PUBLIC RELEASE

UNCLASSIFIED

UNCLASSIFIED

These are readily solved for the two equations in v':-

$$v'^2 = \frac{x + \gamma - 2}{\frac{\gamma}{\gamma - 1}\frac{x}{x - 1} - \frac{1}{2}} u_1 = \frac{(1 - \mu x)}{\frac{\gamma}{\gamma - 1}\frac{\mu x}{1 - \mu x} + \frac{1}{2}} u_o$$

where $u_1 = \frac{1}{\gamma - 1}\frac{p_1}{\rho_1}$ $\qquad u_o = \frac{1}{\gamma - 1}\frac{p_o}{\rho_o}$

and $x = \frac{p'}{p_1}$; $\mu = \frac{p_1}{p_o}$; $\mu x = \frac{p'}{p_o}$.

Now $x >> 1$ and $\mu x << 1$ so that to a good approximation

$$v' = \sqrt{2u_o} \qquad \text{and} \qquad x = \frac{\gamma + 1}{\gamma - 1} \cdot \frac{u_o}{u_1}$$

and the velocity of the rarefaction wave is

$$v = \frac{p_o - p'}{\rho_o v'} \simeq \frac{p_o}{\rho_o v'} = (\gamma - 1)\sqrt{\frac{u_o}{2}}$$

Thus from the equation for v'^2 we see that the kinetic energy of the expanding gas comes out to be approximately equal to the initial internal energy of the detonated explosive. Tables 1 and 2 give some applicable data for several different explosives. As the ideal-gas relation for the internal energy $u_o = \frac{1}{\gamma - 1}\frac{p_o}{\rho_o}$ is not applicable to the highly compressed explosive gas we make direct use of the calorimetric measurements of the energy of explosion and put this equal to u_o.

SECRET

UNCLASSIFIED

TABLE 1. MEASURED HEATS OF EXPLOSION (for loading density 1.5)
(Kistiakowsky, OSRD # 293)

EXPLOSIVE	HEAT OF EXPLOSION	DETONATION VELOCITY (meas.)
TNT	650 cal./g/	6700 meters/sec
Tetryl	890	7200
PETN	1410	7600
Cyclonite (RDX)	1240	7800

TABLE 2. PROPERTIES OF PRODUCTS OF ADIABATIC CONSTANT-VOLUME EXPANSION
(Calculated) (Brinkley and Wilson, OSRD # 1231)

EXPLOSIVE	LOADING DENSITY	TEMPERATURE	PRESSURE
RDX, Comp B	1.61	3140° K	98.8×10^9 dynes/cm^2
TNT	1.46	2910°	65.4
50/50 Amatol	1.58	2480°	79.8

For RDX, density 1.5, one then gets

$$x = \frac{p'}{p_1} = 163$$

$$\frac{1}{\mu x} = \frac{p_o}{p'} = 610$$

$$v' = 3.2 \times 10^5 \text{ cm/sec.}$$

$$v = 0.65 \times 10^5 \text{ cm/sec.}$$

The total momentum given to the projectile per unit sectional area will then be, for small charges of length l_o

$$P = p_o l_o / v = \rho_o l_o v' = m_o v'.$$

Alternatively,

UNCLASSIFIED

(7) $$v_p = \frac{m_o}{m} v' = \frac{m_o}{m}\sqrt{2u_o}$$

is the maximum velocity imparted to the projectile of mass m per unit sectional area.

SECRET

APPROVED FOR PUBLIC RELEASE

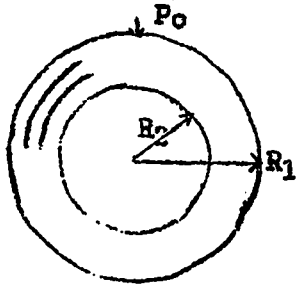
APPROVED FOR PUBLIC RELEASE

This suggests that a somewhat better result may be obtained by a direct overall application of the conservation laws, if one assumes the internal energy to be divided between projectile and ejected gases. The equations are

$$m_o u_o = \frac{m_o}{2} v'^2 + \frac{m}{2} v^2$$

$$m_o v' = mv.$$

The solution is



$$(8) \qquad v = \frac{m_o}{m} v' = \frac{m_o/m}{\sqrt{1 + m_o/m}} \sqrt{2u_o}$$

This is plotted in Fig. 2 for RDX and TNT using the measured values of u_o from Table 1. In the figures and in all that follows the notation m_e, ρ_e, r_e, h_e has been used for the mass, density and dimensions of the explosive charge.

II. MOTION OF THE CYLINDER

The pressure existing in a detonated high explosive is of the order of 10^6 lb/in^2, which is much higher than the yielding strengths of any ordinary metals. In treating the motion of a collapsing shell we therefore assume that there is plastic flow against a constant yielding stress throughout the shell.

For the simple preliminary treatment we ignore volume changes and therefore any effects of elastic waves. The shell is assumed to receive an initial inward impulse from the pressure p_o and thereafter to move freely against the yielding stress. This assumption is not quite valid because the velocity of the rarefaction wave into the exploded gas is $\sim .6 \times 10^5$ cm/sec., which is of the same order as the velocity attained by the shell; this should not however seriously invalidate the results. The motion may then be treated by the energy equation $K = K_o - W$ where K is the

UNCLASSIFIED

APPROVED FOR PUBLIC RELEASE

APPROVED FOR PUBLIC RELEASE

kinetic energy of the shell at any stage of the motion, K_o is the initial kinetic energy, and W is the work done at that stage against the internal stress. If W and K_o are known then the velocities of the inner and outer surfaces can be calculated as a function of the collapse ratios. K_o is calculated from Equation (8). In applying Equations (7) and (8) as approximations to a cylindrical or spherical case it may be noted that in (7) the mass ratio should be taken as $\rho_e t_e/\rho t$ where t_e and t are the thicknesses of explosive and shell, whereas in (8) one should presumably take the actual mass ratio. However, since (8) approaches (7) for small mass ratios and must in any case represent an upper limit, we have used $m_e/m = \rho_e t_e/\rho t$ in all that follows. In the worst case this is about 0.6 the actual mass ratio.

Work of collapse

The pressure required to deform a thin cylindrical shell of radius r and thickness Δr, against a constant yielding stress s, is

$$p = \frac{s\Delta r}{r} .$$

If the volume change is neglected then the volume of the thin shell is $\Delta V = 2\pi r \Delta r = \text{const.}$, and the work required to collapse the shell to a radius r' is

$$\Delta W = -\int_{r}^{r'} 2\pi r p dr = s\Delta V \int_{r}^{r'} dr/r = s\Delta V \ell n(r/r') .$$

Let R_1, r_1 be the initial and final outside radius and R_2, r_2 the initial and final inside radius. The total work to collapse a thick shell from R_1, R_2 to r_1, r_2 is

$$W = s \int \ell n \frac{r}{r'} dV .$$

UNCLASSIFIED

APPROVED FOR PUBLIC RELEASE

APPROVED FOR PUBLIC RELEASE

UNCLASSIFIED

If we use the constant-volume relation

$$r^2 - R_2^2 = r'^2 - r_2^2; \quad R_1^2 - R_2^2 = r_1^2 - r_2^2$$

$$W = \frac{\pi s}{2} \int_{r_2}^{r_1} \ell n \frac{R_2^2 - r_2^2 + r'^2}{r'^2} \, d(r'^2)$$

with the notation

$$\lambda = \frac{R_2}{R_1}; \quad x = \frac{r_1}{R_1}; \quad y = \frac{r_2}{R_1}, \quad \text{(called the "inner collapse ratio")}$$

the total work per unit mass w, may be written

$$(9) \qquad w = \frac{W}{M} = \frac{s/2\rho}{1 - \lambda^2} \left\{ y^2 \ell n y^2 - x^2 \ell n x^2 - \lambda^2 \ell n \lambda^2 \right\}.$$

Here x, y and λ are related by the constant-volume condition

$$x^2 - y^2 = 1 - \lambda^2.$$

In Fig. 3, $w/(s/2\rho)$ is plotted as a function of y for two values of λ. We put $w = v^2/2$ where v is the equivalent initial velocity to produce the collapse ratio y and in Figs. 4 and 5 we plot v against y for three values of the yielding stress and for two values of λ. For these curves $\rho = 7.5$, whereas it should be about 7.8 for the steel cylinders of Part III. The curves of Figs. 6, 7 were derived from Figs. 4, 5 by using Fig. 2 to convert equivalent initial velocity to mass ratio.

Rate of collapse

The kinetic energy may be shown to be

$$K = \frac{M v_2^2}{2} \frac{y^2}{1 - \lambda^2} \ell n \frac{x^2}{y^2} + \frac{M v_2^2}{2} f(y)$$

APPROVED FOR PUBLIC RELEASE

where v_2 is the velocity of the inside surface, and x, y and λ are connected by the same constant volume condition as before: $x^2 - y^2 = 1 - \lambda^2$. If we write $w = (s/2\rho)g(y)$ then the energy equation is

$$(v_2^2/2)\, f(y) = v_o^2/2 + (s/2\rho)\, g(y).$$

This may be used to find v_2 as a function of y for any assumed value of v_o^2. For the case of "critical collapse" $f(0) = 0$, so $v_o^2 = -(s/\rho)\, g(0)$. The kinetic energy function f(y) is plotted in Fig. 8 for various values of λ, and in Fig. 9 the inner velocity for the critical case has been plotted as a function of collapse ratio with $\lambda = .667$, $s = 300{,}000$ lb/in^2. The inner velocity is also shown for the same initial velocity, but no resisting stresses. In this case $v_2 = v_o/\sqrt{f(y)}$.

III. EXPERIMENTAL RESULTS

For the preliminary experiments, which were of necessity done with meagre equipment, the aim has been first to observe the main features of the phenomena when metal shells undergo extreme and rapid plastic flow under external pressure, and to make an empirical determination of the relation between collapse ratio and mass ratio. These experiments are being followed by observations of the velocities and times of collapse, for which several direct methods have been devised.

About 30 experiments have been carried out with mild steel cylinders ranging in diameter from 3" to 6 5/8" and in wall thickness from $\frac{1}{4}$" to $1\frac{1}{2}$". The explosive used first was TNT crystals packed to a density of about 0.87 g/cm^3, and in all the later experiments, a plastic explosive called "Composition C", which is a mixture of finely powdered RDX (88%), also called "Cyclonite", and vegetable oil (12%). An assembly typical of that usually used is shown in Fig. 10, which is drawn to scale for Experiment # 26.

SECRET UNCLASSIFIED

APPROVED FOR PUBLIC RELEASE

APPROVED FOR PUBLIC RELEASE

The results of 16 experiments are listed in Table 3 in which the figure numbers correspond to the photographs. The experiment numbers are marked on the samples in the photographs. All the analyzable data are included in Table 3, as well as a number of typical examples of the sort of fragmentation occurring when large charges are used.

Analysis of the data; stability of collapse

The greatest difficulty in obtaining interpretable experimental results arises from the instability which necessarily exists when the wall thickness is small compared to the radius. This is further enhanced by the non-uniform pressure left by the detonation wave. The detonation wave effect can be reduced by using multiple detonations, started simultaneously by tying several primacords of the same length to one blasting cap; four detonation points, spaced evenly around the circumference at the middle of the cylinder, were used in most cases (see Fig. 10). The effect of the non-uniform pressure left by the detonation wave is shown very strongly in Fig. 14 (Exps. 9 and 11) where there were four evenly spaced detonation points at the ends of the cylinders (at the bottom in the photograph). Even when several detonation points are used there is usually evidence of greater action in the region between detonation points. There are almost always sharply defined lines, along which the detonation waves come together, showing at least a slight etching of the metal and in several cases a strong tendency to shear. This is shown expecially well in Figs. 12 and 13. When shearing rupture occurs it is usually along a surface making an angle of about 45° with a radial plane, which is the direction in which the strain is a simple shear (also in which the shearing strain and stress are a maximum).

It seems likely that fairly uniform collapse can be produced by using a sufficiently large explosive charge; this conclusion follows from the fact that the pressure exerted by the explosive is large compared to the

APPROVED FOR PUBLIC RELEASE

APPROVED FOR PUBLIC RELEASE

strength of the material, and if the shells are given a large enough inward momentum the stresses should play a relatively small part. Experimental evidence for this is shown in Figs. 11, 15, 16, 18 and 19. In Fig. 11, Exp. 1, for example, the steel tube was 3" diameter, $\frac{1}{4}$" wall, with a 3/4" charge of TNT crystals; Exp. 7 was the same except that the charge was $1\frac{1}{2}$" thick. In the first case the tube collapsed more or less uniformly until the wall had thickened to about 5/16", then ruptured into a number of strips which went into an irregular bundle. In the second case the collapse was evidently quite uniform but so violent that the tube bounced out again and fragmented. The thin-walled copper tube of Fig. 15, Exp. 5 is another striking example of the same thing.

In attempting to interpret the data by means of the curves of Figs. 6, 7, only the cases of partial collapse, or else complete collapse without fragmentation could be used. In cases where the collapse was non-uniform, or where rupture occurred, an attempt was still made to estimate the collapse ratio by getting a rough average of the wall thickness. This was done even in the case of Fig. 1, Exp. 1, on the grounds that the work done in the initial thickening of the wall was probably large compared to the work of collapsing the bundle of ruptured strips. The mass ratios $\rho_e h_e / \rho h$ actually used and the ones calculated are listed in Table 3. Five points having $\lambda = .667$ or $.833$ are marked with (*) and plotted in Fig. 6 or 7.

The yielding stress; time of collapse

There is no sound basis for choosing to interpret the data in terms of a yielding stress of 300,000 lb/in^2. This value was quoted to the writer in private conversation as an approximate experimental result for extreme and very rapid deformation, which appeared to be more or less independent of the heat treatment the steel had received. As this value appeared to fit the data for Composition C it was chosen as a reasonable value, although likely to be high. Independent checks of the effective values of s are to

APPROVED FOR PUBLIC RELEASE

APPROVED FOR PUBLIC RELEASE

be made both by calorimetric measurement of the heat of working and by measurements of the rate of collapse.

Two preliminary measurements of the time of collapse, made by a bullet-catching method devised by Streib, for a 3" OD, $\frac{1}{2}$" wall steel cylinder with a $\frac{1}{2}$" charge of Composition C gave times of about 10^{-4} sec. The expected value would be about half this on the basis of 300,000 lb/in^2. These first experimental values should be however essentially upper limits, and further measurements by this and other methods will be the subject of a later report by Streib.

Velocities of projectiles fired with small charges of high explosive

To get some independent information on the relation between terminal velocities and mass ratios, some experiments have been begun by Bradner and Bloch, in which 2" diameter steel projectiles were fired upward with varying charges (confined only by pasteboard and thin wood) of pentolite of the same diameter, pressed to a density 0.45 g/cm^3. Velocities were determined by measuring the time of flight with a stop watch. The data for two projectile sizes are plotted in Fig. 20.

A very rough interpretation of these experiments can be given in terms of the simple one-dimensional theory of Sec. I, if we assume that immediately after detonation the rarefaction wave travels inward from the two free surfaces of the detonated explosive with the same constant velocity. We then assume that the initial pressure p_o acts on the surface of the projectile at any point only until the rarefaction reaches that point, and that the pressure is thereafter negligible. With these simple assumptions we can compute the ratio of the momentum imparted to the projectile to the momentum it should have got if the explosive were free to expand only from the free end surface.

APPROVED FOR PUBLIC RELEASE

APPROVED FOR PUBLIC RELEASE

CLASSIFIED

We get for this ratio

$$P/P_1 = r_e/3l_e \qquad \text{for } r_e < l_e$$
$$= 1 - l_e/r_e + l_e^2/3r_e^2 \qquad \text{for } r_e > l_e,$$

where r_e = radius of projectile and charge, and l_e = length of charge. This factor is applied to the result of the one-dimensional calculation to get the curves of Fig. 20 appropriate to the projectile masses used. Good agreement cannot be expected, but the curves do seem to represent the trend of the experimental data. More complete results will be given in a later report by Bloch and Bradner.

THE LOS ALAMOS PRIMER

UNCLASSIFIED

The following notes are based on a set of five lectures given by R. Serber during the first two weeks of April 1943, as an "indoctrination course" in connection with the starting of the Los Alamos Project. The notes were written up by E. U. Condon.

Bob Serber

1. Object

The object of the project is to produce a practical military weapon in the form of a bomb in which the energy is released by a fast neutron chain reaction in one or more of the materials known to show nuclear fission.

2. Energy of Fission Process

The direct energy release in the fission process is of the order of 170 MEV per atom. This is considerably more than 10^7 times the heat of reaction per atom in ordinary combustion processes.

This is $170 \cdot 10^6 \cdot 4.8 \cdot 10^{-10}/300 = 2.7 \cdot 10^{-4}$ erg/nucleus. Since the weight of 1 nucleus of 25 is $3.88 \cdot 10^{-22}$ gram/nucleus the energy release is

$$7 \cdot 10^{17} \text{ erg/gram}$$

The energy release in TNT is $4 \cdot 10^{10}$ erg/gram or $3.6 \cdot 10^{16}$ erg/ton. Hence

$$1 \text{ kg of } 25 \approx 20000 \text{ tons of TNT}$$

3. Fast Neutron Chain Reaction

Release of this energy in a large scale way is a possibility because of the fact that in each fission process, which requires a neutron to produce it, two neutrons are released. Consider a very great mass of active material, so great that no neutrons are lost through the surface and assume the material so pure that no neutrons are lost in other ways than by fission. One neutron released in the mass would become 2 after the first fission, each of these would produce 2 after they each had produced fission so in the nth generation of neutrons there would be 2^n neutrons available.

Since in 1 kg. of 25 there are $5 \cdot 10^{25}$ nuclei it would require about $n = 80$ generations ($2^{80} \approx 5 \cdot 10^{25}$) to fish the whole kilogram.

While this is going on the energy release is making the material very hot, developing great pressure and hence tending to cause an exposion.

In an actual finite setup, some neutrons are lost by diffusion out through the surface. There will be therefore a certain size of say a sphere for which the surface losses of neutrons are

This document contains information affecting the National Defense of the United States within the meaning of the [redacted] UNCLASSIFIED

UNCLASSIFIED

APPROVED FOR PUBLIC RELEASE

APPROVED FOR PUBLIC RELEASE

on the density. As the reaction proceeds the material tends to expand, increasing the required minimum size faster than the actual size increases.

The whole question of whether an effective explosion is made depends on whether the reaction is stopped by this tendency before an appreciable fraction of the active material has fished.

Note that the energy released per fission is large compared to the total binding energy of the electrons in any atom. In consequence even if but $\frac{1}{2}\%$ of the available energy is released the material is very highly ionized and the temperature is raised to the order of $40 \cdot 10^6$ degrees. If 1% is released the mean speed of the nuclear particles is of the order of 10^8 cm/sec. Expansion of a few centimeters will stop the reaction, so the whole reaction must occur in about $5 \cdot 10^{-8}$ sec otherwise the material will have blown out enough to stop it.

Now the speed of a 1 MEV neutron is about $1.4 \cdot 10^9$ cm/sec and the mean free path between fissions is about 13 cm so the mean time between fissions is about 10^{-8} sec. Since only the last few generations will release enough energy to produce much expansion, it is just possible for the reaction to occur to an interesting extent before it is stopped by the spreading of the active material.

Slow neutrons cannot play an essential role in an explosion process since they require about a microsecond to be slowed down in hydrogenic materials and the explosion is all over before they are slowed down.

4. Fission Cross-sections

The materials in question are $U_{92}^{235} = 25$, $U_{92}^{238} = 28$ and element $94^{239} = 49$ and some others of lesser interest.

Ordinary uranium as it occurs in nature contains about 1/140 of 25, the rest being 28 except for a very small amount of 24.

The nuclear cross-section for fission of the two kinds of U and of 49 is shown roughly in Fig. 1 where σ_f is plotted against the log of the incident neutron's energy. We see that 25 has a cross-section of about $\sigma_f \approx 1.5 \cdot 10^{-24}$ cm^2 for neutron energies exceeding 0.5 MEV and rises to much higher values at low neutron energies ($\sigma_f = 640 \cdot 10^{-24}$ cm^2 for thermal neutrons). For 28 however a threshold energy of 1 MEV occurs below which $\sigma_f = 0$. Above the threshold σ_f is fairly constant and equal to $0.7 \cdot 10^{-24}$ cm^2.

(thermal) log neutron energy in EV.

5. Neutron Spectrum

In Fig. 2 is shown the energy distribution of the neutrons released in the fission process. The mean energy is about 2 MEV but an appreciable fraction of the neutrons released have less than 1 MEV of energy and so are unable to produce fission in 28.

One can give a quite satisfactory interpretation of the energy distribution in Fig. 2 by supposing it to result from evaporation of neutrons from the fission product nuclei with a temperature of about $\frac{1}{2}$ MEV. Such a Maxwellian velocity distribution is to be relative to the moving fission product nuclei giving rise to a curve like Fig. 2.

Fig. 2

neutron energy in MEV

6. Neutron number

The average number of neutrons produced per fission is denoted by ν. It is not known whether ν has the same value for fission processes in different materials, induced by fast or slow neutrons or occurring spontaneously.

The best value at present is

$$\nu = 2.2 \pm 0.2$$

although a value $\nu = 3$ has been reported for spontaneous fission.

7. Neutron capture

When neutrons are in uranium they are also caused to disappear by another process represented by the equation

$$28 + n \rightarrow 29 + \gamma$$

The resulting element 29 undergoes two successive β transformations into elements 39 and 49. The occurrence of this process in 28 acts to consume neutrons and works against the possibility of a fast neutron chain reaction in material containing 28.

It is this series of reactions, occurring in a slow neutron fission pile, which is the basis of a project for large scale production of element 49.

SECRET

8. Why ordinary U is safe

Ordinary U, containing only 1/140 of 25, is safe against a fast neutron chain because, (a) only 3/4 of the neutrons from a fission have energies above the threshold of 28, (b) only $\frac{1}{4}$ of the neutrons escape being slowed below 1 MEV, the 28 threshold before they make a fission.
So the effective neutron multiplication number in 28 is

$$\nu \approx 3/4 \times 1/4 \times 2.2 = 0.4$$

Evidently a value greater than 1 is needed for a chain reaction. Hence a contribution of at least 0.6 is needed from the fissionability of the 25 constituent. One can estimate that the fraction of 25 must be increased at least 10-fold to make an explosive reaction possible.

9. Material 49

As mentioned above this material is prepared from the neutron capture reaction in 28. So far only microgram quantities have been produced so bulk physical properties of this element are not known. Also its ν value has not been measured. Its σ_f has been measured and found to be about twice that of 25 over the whole energy range. It is strongly α-radioactive with a half-life of about 20000 years.

Since there is every reason to expect its ν to be close to that for U and since it is fissionable with slow neutrons it is expected to be suitable for our problem and another project is going forward with plans to produce it for us in kilogram quantities.

Further study of all its properties has an important place on our program as rapidly as suitable quantities become available.

10. Simplest Estimate of Minimum Size of Bomb

Let us consider a homogeneous material in which the neutron number is ν and the mean-time between fissions is τ. In Sec. 3 we estimated $\tau = \cdot\ 10^{-8}$sec. for uranium. Then if N is the number of neutrons in unit volume we have

$$\dot{N} + \operatorname{div} \underline{j} = \frac{\nu - 1}{\tau} N$$

The term on the right is the net rate of generation of neutrons in unit volume. The first term on the left is the rate of increase of neutron density. In the second term on the left $\underline{j}$ is the net diffusion current stream of the neutrons (net number of neutrons crossing 1 cm^2 in 1 sec across a plane oriented in such a way that this net number is maximum).

In ordinary diffusion theory (which is valid only when all dimensions of boundaries are large compared to the mean free path of the diffusing particles - a condition not fulfilled in our case) the diffusion current is proportional to the gradient of N,

$$\underline{j} = -D \operatorname{grad} N$$

SECRET

where D is the diffusion coefficient (cm^2/sec).

Hence we have

$$\dot{N} = D\Delta N + \left(\frac{\nu-1}{\tau}\right)N$$

UNCLASSIFIED

Assume a solution whose time dependence is of the form

$$N = N_1(x,y,z)\, e^{\nu' t/\tau}$$

where ν' is called the "effective neutron number". The equation to be satisfied by N_1 is

$$\Delta N_1 + \frac{-\nu'+\nu-1}{D\tau} N_1 = 0$$

together with a boundary condition. In the simple case in which we are dealing with a sphere of radius R, we may suppose that N_1 is spherically symmetric.

At $r=R$ we would have, on simple theory $N_1 = 0$. (In point of fact $N_1 > 0$ due to the effect of the mean free path's not being small compared with R, but this will not be considered here). For spherical symmetry the equation for N_1 has the solution

$$N_1(r) = \frac{\sin(\pi r/R)}{r}$$

provided that ν' has the value

$$\nu' = (\nu-1) - \pi^2 D\tau/R^2.$$

This shows that in an infinitely large sphere the neutron density would build up with the time constant $(\nu-1)/\tau$. Smaller spheres build up less rapidly. Any sphere so small that $\nu' < 0$ is one for which the neutrons leak out the surface so rapidly that an initial density will die out rather than build up. Hence the critical radius is given by

$$R_c^2 = \frac{\pi^2 D\tau}{\nu-1} \qquad \nu'=0$$

Now D is given by $D = \lambda v/3$ where λ is the transport mean free path, $\lambda = 1/n\sigma_t$, n is the number of nuclei per cc and

$$\sigma_t = \left[\sigma_f + \int\int \sigma_s(1-\cos\theta)\,d\omega\right]$$

which brings out the reason for measurements of the angular scattering of neutrons in U. In metallic U we have

$$\sigma_t = 4\cdot 10^{-24}\ cm^2.$$

which, for a density of 19 gm/cm^3, gives $\lambda = 5$ cm.
Also

$$\tau = \frac{1}{n\sigma_f v} = \frac{\ell}{v}\frac{\sigma_t}{\sigma_f} \quad \text{so } \pi^2 D\tau = \frac{\pi^2}{3}\ell^2\frac{\sigma_t}{\sigma_f} = 220.$$

Therefore

$$R_c^2 = \frac{220}{1.3} = 183 \text{ and } R_c = 13.5\ cm.$$

The critical volume is therefore $10.5\cdot 10^3$ cm^3 giving a critical mass of 200 kilograms.

APPROVED FOR PUBLIC RELEASE

SECRET
LIMITED

The designated "LIMITED" indicates a report [redacted] information in the usual secret [redacted] receiving these reports [redacted] members of the project even of the same laboratory without specific authorization.

Exercise: Show that if the gadget has the shape of a cube, $0<x<a$, $0<y<a$, $0<z<a$, that the critical value of a is given by

$$a = \sqrt{3}\, R_c$$

Hence the critical mass for a cubical shape is $3^{5/2}/4\pi = 1.24$ times as great as for a sphere.

The value of the critical mass is, however, considerably overestimated by the elementary diffusion theory. The more exact diffusion theory allowing for the long free path drops Rc by a factor about 2/3 giving

$$R_c \sim 9\ \text{cm} \qquad M_c \sim 60\ \text{kg of 25.}$$

The elementary treatment just given indicates the dependence of M_c on the principal constants

$$M_c \sim \frac{1}{\rho^2}\left[\frac{1}{\sigma_f \sigma_t (\nu-1)}\right]^{3/2}$$

where ρ is the density. For $R \neq R_c$ we have the time dependence of neutron multiplication given by

$$e^{(\nu-1)t\left[1-\left(\frac{R_c}{R}\right)^2\right]/\tau}$$

Hence for a sphere of twice the critical mass the time constant, for multiplication of neutron density by e is 2.4×10^{-8} sec.

11. Effect of Tamper

If we surround the core of active material by a shell of inactive material the shell will reflect some neutrons which would otherwise escape. Therefore a smaller quantity of active material will be enough to give rise to an explosion. The surrounding case is called a tamper.

The tamper material serves not only to retard the escape of neutrons but also by its inertia to retard the expansion of the active material. (The retardation provided by the tensile strength of the case is negligible.) For the latter purpose it is desirable to use the densest available materials (Au, W, Re, U). Present evidence indicates that for neutron reflecting properties also, one cannot do better than use these heavy elements. Needless to say, a great deal of work will have to be done on the properties of tamper materials.

We will now analyze the effect of tamper by the same approximate diffusion theory that was used in the preceding section. Let D' be the diffusion coefficient for fast neutrons in the tamper material and suppose the lifetime of a neutron in the tamper is α/τ. Here $\alpha = n'\sigma'_{cap}/n\sigma_f$, with n' the nuclear density of the tamper and σ'_{cap} its capture cross-section. If the tamper material is itself fissionable (U tamper) the absorption coefficient is reduced by a factor $(1-\nu_t)$, with ν_t the number of neutrons produced per capture.

At the boundary between active material and tamper, the diffusion stream of neutrons must be continuous so

APPROVED FOR PUBLIC RELEASE

[redacted] SECRET

$$D\left(\frac{\partial N}{\partial r}\right)_{active} = D'\left(\frac{\partial N}{\partial r}\right)_{tamper}$$

In the tamper the equation for neutron density is

$$\dot{N} = D'\triangle N - \frac{\alpha}{T}N$$

or for the spatial dependence,

$$\triangle N_1 - \frac{\nu' + \alpha}{D'T} N_1 = 0$$

As an easy special case suppose the tamper has the same neutron diffusion coefficient as the active material (i.e. the same mean free path) but has no absorption, so $\alpha = 0$. Then under critical conditions ($\nu' = 0$) we have

$$N_1 = A/r + B$$

in the tamper material and

$$N_1 = \frac{\sin kr}{r}$$

in the active material.

At the outer boundary of the tamper, $r = R'$, we must have $N_1 = 0$ hence

$$N_1 = A\left(\frac{1}{r} - \frac{1}{R'}\right)$$

On each side of the boundary $r = R$ between active material and tamper material, the slopes must be equal so, equating the densities and slopes on both sides of the boundary we find the following equation to determine k,

$$kR\cos kR + \frac{R/R'}{1 - R/R'}\sin kR = 0$$

In the limit of a very large tamper radius $R' \to \infty$ this requires that

$$k = \pi/2R$$

which is just half the value it had in the case of the untampered gadget. Hence the critical mass needed is <u>one-eighth</u> as much as for the bare bomb.

Actually on better theory the improvement is not as great as this because the edge effect (correction for long free path) is not as big in this case as in the bare bomb. Hence the improvement of non-absorptive equal diffusion tamper over the critical mass, both handled by more accurate diffusion theory only turns out to be a factor of <u>four</u> instead of <u>eight</u>.

<u>Exercise:</u>

Consider a non-absorptive tamper material for which the diffusion coefficient D' is small compared to D. In the limit if $D' = 0$, no neutrons could escape from the active material by diffusion, so the critical radius would vanish and <u>any</u> amount of active core would be explosive.

The design [redacted] is a report with information which is more restricted than the [redacted] formation in the usual secret report. [redacted] or the [redacted] manner to [redacted] without specific authorization.

[redacted] SECRET

APPROVED FOR PUBLIC RELEASE

UNCLASSIFIED

APPROVED FOR PUBLIC RELEASE

UNCLASSIFIED

To get an idea of the improvement obtainable from tamper material of shorter mean free path than the active material show that if $D' = \frac{1}{2}D$ then the critical mass is 1/2.40 times what it is in the case of thick tamper ($R' = \infty$) if $D' = D$. From this we see that it would be very much worth while to find tamper materials of low diffusion coefficient.

(It turns out that $\chi = kR$ is a root of

$$\chi \cos \chi = (1 - D'/D) \sin \chi$$

which is 1.17 approximately when $D'/D = 0.5$.)

If the tamper material is absorptive then the neutron density in it will fall off like e^{-kr}/r instead of 1/r which tends to make the critical mass greater than if the tamper did not absorb.

The distance the neutrons get into the tamper is $1/k = \ell' \sqrt{\frac{s}{3(1-\nu_t)}}$ where ℓ' is the mean free path and s the number of collisions before capture. Guessing $s \sim 20$ this gives, with $\ell' = 5$ cm, an effective tamper thickness $\sim$ 13cm. For a U tamper $\nu_t \sim 0.6$, and the effective thickness is raised to 17 cm. These figures give an idea of the tamper thickness actually required; the weight of the tamper is about a ton.

For a normal U tamper the best available calculations give R_c = 6 cm and M_c = 15 Kg of 25 while with Au tamper M_c = 22 kg of 25.

The critical mass for 49 might be, because of its larger fission cross section, less than that of 25 by about a factor 3. So for 49

M_c = 5 Kg for U tamper

M_c = 7.5 Kg for Au tamper.

These values of critical masses are still quite uncertain, particularly those for 49. To improve our estimates requires a better knowledge of the properties of bomb materials and tamper: neutron multiplication number, elastic and inelastic cross sections, overall experiments on tamper materials. Finally however, when materials are available, the critical masses will have to be determined by actual test.

12. Damage

Several kinds of damage will be caused by the bomb.

A very large number of neutrons is released in the explosion. One can estimate a radius of about 1000 yards around the site of explosion as the size of the region in which the neutron concentration is great enough to produce severe pathological effects.

Enough radioactive material is produced that the total activity will be of the order of 10^6 curies even after 10 days. Just what effect this will have in rendering the locality uninhabitable depends greatly on very uncertain factors about the way in

The de... with informat... ...rmation ...iving ... members of the pro... without spec...

which this is dispursed by the explosion. However the total amount of radioactivity produced, as well as the total number of neutrons, is evidently proportional just to the number of fission processes, or to the total energy released.

The mechanical explosion damage is caused by the blast or shock wave. The explosion starts acoustic waves in the air which travel with the acoustic velocity, c, superposed on the velocity u of the mass motion with which material is convected out from the center. Since $c \sim \sqrt{T}$ where T is the absolute temperature and since both u and c are greater farther back in the wave disturbance it follows that the back of the wave overtakes the front and thus builds up a sharp front. This is essentially discontinuous in both pressure and density.

It has been shown that in such a wave front the density just behind the front rises abruptly to six times its value just ahead of the front. In back of the front the density falls down essentially to zero.

If E is the total energy released in the explosion it has been shown that the maximum value of the pressure in the wave front varies as

$$p \sim E/r^3$$

the maximum pressure varying as $1/r^3$ instead of the usual $1/r^2$ because the width of the strongly compressed region increases proportionally to r.

This behavior continues as long as p is greater than about 2 atmospheres. At lower pressures there is a transition to ordinary acoustic behavior the width of the pulse no longer increasing.

If destructive action may be regarded as measured by the maximum pressure amplitude, it follows that the radius of destructive action produced by an explosion varies as $\sqrt[3]{E}$. Now in a $\frac{1}{2}$ ton bomb, containing $\frac{1}{4}$ ton of TNT the destructive radius is of the order of 150 feet. Hence in a bomb equivalent to 100000 tons of TNT (or 5 kg of active material totally converted) one would expect a destructive radius of the order of $\sqrt[3]{400000} \times 150 = 1.1 \times 10^4$ feet or about 2 miles.

This points roughly to the kind of results which may be expected from a device of the kind we hope to make. Since the one factor that determines the damage is the energy release, our aim is simply to get as much energy from the explosion as we can. And since the materials we use are very precious, we are constrained to do this with as high an efficiency as is possible.

13. Efficiency

As remarked in Sec. 3, the material tends to blow apart as the reaction proceeds, and this tends to stop the reaction. In general then the reaction will not go to completion in an actual gadget. The fraction of energy released relative to that which would be released if all active material were transformed is called the efficiency.

Let R_{co} = critical radius figured for normal density ρ_o, also R_o initial radius and R = radius at a particular instant. Assume homogeneous expansion. Then the density when expanded is

$$\rho = \rho_o (R_o / R)^3$$

and the critical radius R_c figured with the actual density ρ is

$$R_c = R_{co} (\rho_o / \rho)$$

The reaction will proceed until expansion has gone so far that $R_c = R$. Therefore the radius R at which expansion stops is given by

$$R / R_o = \sqrt[3]{R_o / R_{co}}$$

Since the ratio of R_o / R_{co} is equal to the cube root of the ratio of M_o, the actual active mass, to M_c the critical mass we see that

$$R / R_o = \sqrt[3]{M_o / M_{co}}$$

and therefore a gadget having twice the critical mass will expand to a radius only $\sqrt[3]{2} = 1.12$ times its original radius before the reaction stops.

The next problem is to find a simple expression for the time taken for this expansion to occur, since we already know how to calculate the time constant ν'/τ of the reaction. Of course ν' is not a constant during the expansion since its value depends on the radius but this point will be ignored at first.

At a place where we have N neutrons/cm^3 there will be N/τ fissions/cm^3 sec and therefore if ε is the energy release in erg/fission the volume rate of energy generation is $(\varepsilon/\tau)N$. Hence the total energy released in unit volume between time $-\infty$ and time t is

$$W = (\varepsilon/\nu') N e^{\nu' t/\tau}$$

Most of this energy goes at once into kinetic energy of the fission fragments which are quickly brought to rest in the material by communication of their energy largely to thermal kinetic energy of motion to the other atoms of the active stuff.

The course of events is shown in Fig. 3. The units on the scale of abscissas are units of $\nu' t/\tau$. If there was no expansion, and if the rate of reaction toward the end was not slowed down by depletion of active material, then the energy released up to a given time in erg/cm^3 would be given by the values on the upper logarithmic scale. The places on this scale marked 100%, 10% and 1% respectively show the energy released in unit volume for these three values of the efficiency. A second logarithmic scale shows the growth of the neutron density with time under these assumptions.

It can be calculated that the pressure in atmospheres is very roughly like the values given on the third scale. At a point just below 10^{17} erg/cm^3 evolved the radiation pressure is equal to the gas pressure, after that radiation pressure predominates. Near 10^{10} erg/cm^3 is the place where the solid melts so up to this time nothing very drastic has happened - the important phenomena occur in the next 20 units of $\nu' t/\tau$.

Very roughly we may estimate, as follows for masses not much larger than the critical mass, the combination of factors on which the efficiency depends: In a time of the order τ/ν' the material moves from R_0 to R so acquires a velocity

$$v \sim (\nu'/\tau)(R - R_0)$$

Writing $R_0 = R_{c0}(1+\Delta)$ we find that

$$R - R_0 = \tfrac{1}{2}\Delta R_{c0}$$

The kinetic energy per gram that is acquired by the material is

$$v^2/2 \sim \tfrac{1}{4}(\nu'/\tau)^2 \Delta^2 R_{cc}^2$$

The total energy released is greater in the order $pV \div pdV$ or $2/3\Delta$. Let $\mathcal{E} = 7.10^{17}$ erg/gram be the energy release for complete conversion then the efficiency is of the order

$$f \approx (\nu'^2/\mathcal{E}\tau^2)(\Delta^2/4) R_{c0}^2 (2/3\Delta)$$

or

$$f \approx (1/6)(\nu'^2/\mathcal{E}\tau^2) R_{c0}^2 \Delta$$

For an untampered gadget

$$\nu' \approx 2(\nu-1)\Delta$$

giving

$$\boxed{f = \frac{2}{3}\frac{(\nu-1)^2 R_{c0}^2}{\mathcal{E}\tau^2}\Delta^3}$$

Putting in the known constants

$$\mathcal{E} = 7.10^{17} \qquad \tau = 10^{-8} \qquad R_c = 9$$

we find

$$f = K\Delta^3 \quad \text{with} \quad K = 1.1$$

If this very rough calculation is replaced by a more accurate one the only change is to alter the value of the coefficient K. The calculations are not yet complete, but the true value is probably $K \approx \frac{1}{4}$ to $\frac{1}{2}$.

Hence for a mass that is twice the critical mass, $R_0 = \sqrt[3]{2}\, R_c$ so $\Delta = 0.25$ and the efficiency comes out less than 1%. We see that the efficiency is extremely low even when this much valuable material is used.

Notice that τ varies inversely as the velocity of the neutrons. Hence it is advantageous for the neutrons to be fast. The efficiency depends on the nuclear properties through the factors

$$f \sim \frac{v^2(\nu-1)}{\mathcal{E}}\frac{\sigma_f}{\sigma_t}\Delta^3$$

where v is the mean speed of the neutrons and the other symbols are already defined.

In the above treatment we have considered only the effect of the general expansion of the bomb material. There is an additional effect which tends to stop the reaction: as the pressure builds up it begins to blow off material at the outer edge of the bomb. This turns out to be of comparable importance in

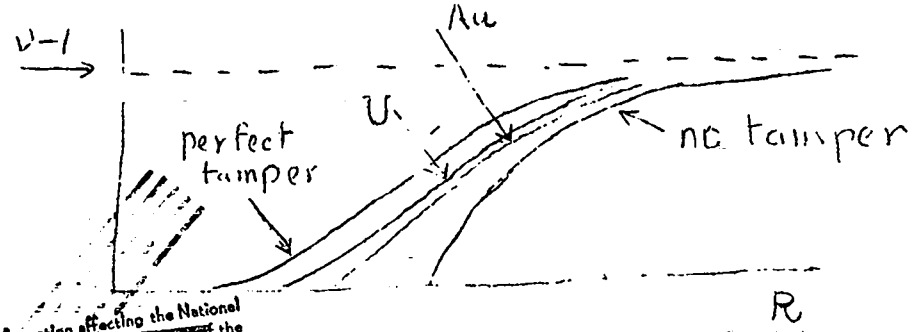
UNCLASSIFIED UNCLASSIFIED

stopping the reaction to the general expansion of the interior. However the formula for the efficiency can be shown to be unchanged in form; the edge expansion manifests itself simply in a reduction in the constant K. The effect of blowing off the edge has been already taken into account in the more accurate estimate of K given above.

14. Effect of Tamper on Efficiency



For a given mass of active material, tamper always increases efficiency. It acts both to reflect neutrons back into the active material and by its inertia to slow the expansion thus giving opportunity for the reaction to proceed farther before it is stopped by the expansion.

However the increase in efficiency given by a good tamper is not as large as one might judge simply from the reduction in the critical mass produced by the tamper. This is due to the fact that the neutrons which are returned by diffusion into and back out of the tamper take a long time to return, particularly since they are slowed down by inelastic impacts in the tamper material.

The time scale, for masses near critical where one has to rely on the slowest neutrons to keep the chain going, now becomes effectively the lifetime of neutrons in the tamper, rather than the lifetime in the bomb. The lifetime of neutrons in a U tamper is $\sim 10^{-7}$ sec, ten times that in the bomb. The efficiency is consequently very small just above the critical mass, so to some extent the reduction in critical mass is of no use to us.

One can get a picture of the effect of tamper on efficiency from Fig. 4, in which U ν' is plotted against bomb radius for various tamper materials. The time scale is given by τ/ν' ; the efficiency, as we have seen in the preceeding section, is inversely proportional to the square of the time scale. Thus $f \sim \nu'^2$.

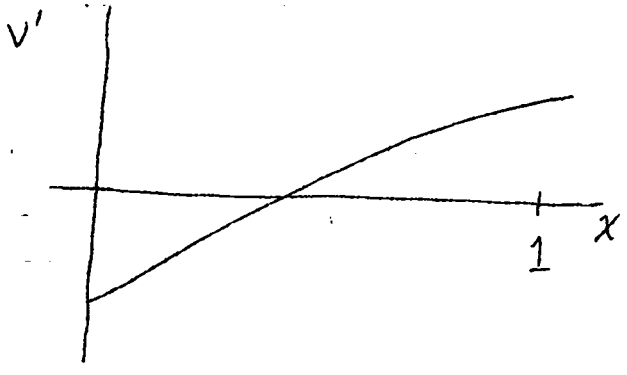
If we use good tamper (U) the efficiency is very low near the critical mass due to the small slope of the ν' vs.R curve near $\nu' = 0$. When one uses a mass sufficiently greater than the critical to get good efficiency there is not very much difference between U and Au as tamper materials.

It turns out that if one is using 4 M_c and the U tamper, then only about 15% more active material is needed to get the same energy release with a gold tamper, although the critical masses differ by 50%.



In addition to reflecting neutrons, the tamper also inhibits the tendency of the edge of the bomb to blow off. The edge expands into the tamper material, starting a shock wave which compresses the tamper material sixteenfold. These edge effects as remarked in Sec. 13 always act to reduce the factor K in the formula, $f = K\Delta^3$, but not by as great an amount in the case of tamped bomb as in the case of the untamped bomb.

15. Detonation

Before firing, the active material must be disposed in such a way that the effective neutron number ν' is less than unity. The act of firing consists in producing a rearrangement such that after the rearrangement ν' is greater than unity.

This problem is complicated by the fact that, as we have seen, we need to deal with a total mass of active material considerably greater than the critical in order to get appreciable efficiency.

For any proposed type of rearrangement we may introduce a coordinate χ which changes from 0 to 1 as the rearrangement of parts proceeds from its initial to its final value.

Schematically ν' will vary with χ along some such curve as is indicated in the sketch. Since the rearrangement proceeds at a finite speed there will be a finite time interval during which ν' though positive is much smaller than its final value. As considered in more detail later there will always be some un-

SECRET UNCLASSIFIED LIMITED

avoidable sources of neutrons in the active material. In any scheme of rearrangement some fairly massive amount of material will have to be moved a distance of the order of $R_c \sim 10$ cm. Assuming a speed of 3000 ft/sec can be imparted with some type of gun this means that the time it takes to put the pieces of the bomb together is $\sim 10^{-4}$ sec. Since the whole explosion is over in a time $\sim 75\,\tau/\nu' = \frac{10^{-6}}{\nu'}$ sec, we see that, except for very small ν' ($\nu' < .01$), an explosion started by a premature neutron will be all finished before there is time for the pieces to move an appreciable distance. Thus if neutron multiplication happens to start before the pieces reach their final configuration an explosion will occur that is of lower efficiency corresponding to the lower value of ν' at the instant of explosion.

To avoid predetonation it is therefore necessary to keep the neutron background as low as possible and to effect the rearrangement as rapidly as possible.

16. Probability of Predetonation

Since it will be clearly impossible to reduce the neutron background rigorously to zero, there will always be some chance of predetonation. In this section we try to see how great this chance is in order to see how this affects the firing problem.

The chance of predetonation is dependent on the likelihood of a neutron appearing in the active mass while ν' is still small and on the likelihood that such a neutron will really set off a chain reaction. With just a single neutron released when $\nu' > 0$ it is by no means certain that a chain reaction will start, since any particular neutron may escape from the active material without causing a chain reaction.

The question can be considered in relation to a little gambling problem. In tossing loaded coins suppose p is the probability of winning and q that of losing. Let P_n be the probability of losing all of an initial stock of n coins. On the first toss either one wins and thus has $(n+1)$ coins or loses and thus has $(n-1)$ coins. Hence the probability P_n is given by

$$P_n = p\,P_{n+1} + q\,P_{n-1}$$

the solution of which is

$$P_n = (q/p)^n$$

Identifying this with the neutron multiplication problem one can show that $q/p = 1 - \nu'$. Hence the probability of not starting a chain reaction with one neutron is $(1 - \nu')$ or ν' is the probability that any one neutron will start a chain reaction.

Suppose now that there is a source of N neutron/sec. Let $P(t)$ be the probability of not getting a predetonation up to the instant t. In the interval dt we have

$$dP = -N dt\, \nu' P$$

On the left the first three factors together give the probability of going off in a time dt, and the factor P is the probability of not having had a predetonation up to that time.

Near the value $\nu' = 0$ we may suppose that ν' varies linearly with time, $\nu' = \alpha t$. Hence, integrating the differential equation,

$$P = e^{-\frac{1}{2} N t^2} = e^{-\frac{1}{2} \frac{N}{\alpha} \nu'^2}$$

ceiving these ... of the same ... members of ... without specific authorization

where $N = Nt$ is the number of neutrons expected in the interval between $t = 0$, when $\nu' = 0$, and the time when the multiplication number has reached the value ν'. Evidently for a particular type of firing rearrangement N will vary inversely as the velocity with which the firing rearrangement is carried out.

For example consider a bomb whose mass is between two and three critical masses, for which the final value of ν' is 0.3 and suppose that $N = 10^4$ neutrons/sec from unavoidable sources. Also suppose that one piece must move $d = 10$ cm from the $\nu' = 0.0$ configuration to the final $\nu' = 0.3$ configuration. Suppose that this piece has a velocity of 10^5 cm/sec then $\bar{N} = 1$ and

$$P = e^{-0.15}$$

so there is approximately a 15% chance of predetonation.

This is the chance of predetonation any time up to that at which the final value of ν' is reached. In this example the exponent is small enough that the chance of predetonation, $(1 - P)$, is given by the linear approximation.

$$(1 - P) = \frac{1}{2} \bar{N} \nu'$$

Since the efficiency varies as ν'^3 one will get an explosion of less than $\frac{1}{4}$ of the maximum if it goes off before ν' has reached the value $0.3/\sqrt[3]{4} = 0.19$. Hence the probability of an explosion giving less than 25% of the maximum value is

$$(.19/.3)^2 \times .15 = 6\%$$

The example serves to indicate the importance of taking great pains to get the least possible neutron background, and of shooting the firing rearrangement with the maximum possible velocity. It seems one should strive for a neutron background of 10000 neutron/sec or less and firing velocities of 3000 ft/sec or more. Both of these are difficult of attainment.

17. Fizzles

The question now arises: what if by bad luck or because the neutron background is very high, the bomb goes off when ν' is very close to zero? It is important to know whether the enemy will have an opportunity to inspect the remains and recover the material. We shall see that this is not a worry; in any event the bomb will generate enough energy to completely destroy itself.

It has been remarked in the last section that for very small ν' ($\nu' < .01$), the explosion takes so long that the pieces do have time to move an appreciable distance before the reaction ends. Thus even if a neutron enters and starts a chain just when $\nu' = 0$ there will be time for ν' to rise to a positive value, and give an efficiency small, but greater than zero.

Suppose, then, that a neutron is released when $\nu' = 0$. The number of neutrons builds up according to the equation

$$N = e^{(\nu' - 1)N}$$

As a first approximation we may suppose ν' varies linearly as the pieces move from the point where $\nu' = 0$, so

$$\nu' = \nu'_0 \left(\frac{x}{d}\right)$$

where ν'_0 is the value of ν' when the pieces reach their final op-

timal configuration, and d_0 is the distance to reach this configuration. If the velocity of fire is v, we have $x = vt$,

$$\ln N = \int_0^t (\nu'/\tau)\,dt = \frac{1}{2}\frac{\nu_0 v}{d_0 \tau} t^2$$

Suppose the reaction continues until about 10^{22} neutrons are produced, which would correspond to an energy production equivalent to 100 tons of TNT. Then, at the end of the reaction

$$\ln N = \ln 10^{22} \simeq 50.$$

(We can check this assumption after we have completed our estimate of the energy release. However, since the final number of neutrons enters only in the logarithm of a large number, our result is quite insensitive to what we take for N at this point.)

Thus the reaction ends when

$$\frac{1}{2}\frac{\nu_0 v}{d_0 \tau} t^2 = 50 \qquad x^2 = v^2 t^2 = 100 \frac{d_0 v \tau}{\nu_0} \qquad \nu' = \nu_0 \frac{x}{d_0}$$

$$= 10\sqrt{\nu_0 \frac{v\tau}{d_0}}$$

The efficiency is

$$f \sim \frac{1}{2}\nu'^3 = 500\,\nu_0^{3/2}\left(\frac{v\tau}{d_0}\right)^{3/2}$$

Using the same figures as in the precoeding section $(\nu_0 = .3,\ v = 10^5,\ d_0 = 10)$ we find $f = 8 \times 10^{-5}$

The mass of 25 in the bomb is about 40 kg. The mass used up is thus $40 \times 8 \times 10^{-3} = .003$ kg, and the energy release is .003 x 20000 = 60 tons of TNT equivalent, ample to destroy the bomb.

18. Detonating Source

To avoid predetonation we must make sure that there is only a small probability of a neutron appearing while the pieces of the bomb are being put together. On the other hand, when the pieces reach their best position we want to be very sure that a neutron starts the reaction before the pieces have a chance to seperate or break. It may be possible to make the projectile seat and stay in the desired position. Failing in this, or in any event as extra insurance, another possibility is to provide a strong neutron source which becomes active as soon as the pieces come into position. For example one might use a Ra + Be source in which the Ra is on one piece and the Be on the other so neutrons are only produced when the pieces are close to the proper relative position.

We can easily estimate the strength of source required. After the source starts working, we want a high probability of detonation before the pieces have time to move more than say 1 cm. This means that N, the neutrons/sec from the source must be large enough that

$$\frac{1}{2}\frac{N d \nu'}{v} \gg 1 \quad (\text{say} = 10)$$

$$N = 10^7 \text{ neutrons/sec.}$$

This is the yield from 1 gr Ra intimately mixed with beryllium. Hence it might be necessary to ~~rise~~ several grams of radium since it will probably not be used efficiently in this type of source.

Some other substance such as polonium that is not so γ-active as radium will probably prove more satisfactory.

Evidently a source of this strength that can be activated within about 10^{-5} sec and is mechanically rugged enough to stand the shocks associated with firing presents a difficult problem.

19. Neutron Background

There are three recognized sources of neutrons which provide the background which gives rise to danger of predetonation: (a) cosmic ray neutrons, (b) spontaneous fission, (c) nuclear reactions which produce neutrons.

(a) Cosmic Rays. The number of cosmic ray neutrons is about 1 per cm^2 per minute which is too few to be of any importance.

(b) Spontaneous fission. The spontaneous fission rate is known only for 28 which is responsible for the fission activity of ordinary U. At present we have only upper limits for 25 and 49 since the activity of these has not been detected. The known facts are

28 gives 15 neutrons/kg sec.
25 " < 150 "
49 " < 500 "

It is considered probable that the rates for 25 and 49 are much smaller than these upper limits. Even if 25 and 49 were the same as 28, a 40 kg bomb would have a background from this source of 600 neutron/sec. This does not seem difficult to beat.

But if U is used as tamper this will weigh about a ton which gives 15000 neutron/sec. Of course not all of these will get into the active material but one may expect a background of several thousand per second from this source.

Thus with a U tamper one is faced with the problem of high velocity firing. In the range of moderately high efficiencies, say 4 M_c of active material, it might for this reason not be worth while to use a U tamper, since as we have seen, an inactive tamper will cost only about 15% more active material. Or one might use a compromise in which the tamper was an inner layer of U, backed up by inactive material; for masses this large the time scale is so short that neutrons do not have time to penetrate more than about 5 cm into the tamper anyway.

(c) Nuclear reactions. The only important reactions are the (α, n) reactions of light elements which might be present as impurities. The (γ, n) reactions have a negligible yield.

...ing the ... within the ... S. C. 50-31 and ... the revelation of its contents ... unauthorized person is pro-hibited by law.

UNCLASSIFIED SECRET ...LIMITED UNCLASSIFIED

Let us examine what sort of limit on light element impurities in the active material is set by the need of holding down the neutron background from this source.

The problem is particularly bad for 49 since its half-life is only 20000 years. Its mean life is thus 30000 years $= 10^{12}$ sec. Thus 10 kg of 49, containing 2.5×10^{25} nuclei gives 2.5×10^{13} α-particles/sec.

The yield from Ra α's on Be is 1.2×10^{-4} and the shorter range from α's of 49 as compared with those of Ra and its equilibrium products will perhaps cut this figure in half, say $6 \cdot 10^{-5}$. Since the stopping power for α's of these energies is proportional to $\sqrt{A}$ where A is the atomic weight, the stopping power per gram is proportional to $1/\sqrt{A}$.

If the concentration by weight of Be in the active material is C then the yield of neutron/sec is

$$\sqrt{239/9} \cdot c \cdot N_\alpha \cdot y$$

where N_α is the number of α's per second and y is the yield. Hence to get 10000 neutrons/sec one would need to have a concentration given by

$$\sqrt{239/9} \cdot c \cdot 2.5 \cdot 10^{13} \cdot 6 \times 10^{-5} = 10^4$$

that is $c \sim 10^{-6}$ which is, of course, a very low concentration of anything in anything else.

The yield drops rapidly as one goes to elements of higher atomic weight because of the increased Coulomb barrier. So it is unnecessary to consider limits on elements beyond Ca as long as ordinary standards of purity are maintained.

Experiments on the yields with light elements need to be done. One can base some rough guesses on the standard barrier penetration formulas and find the following upper limits on the concentration by weight for several light elements for production of 10^4 neutron/sec/

Li	2×10^{-5}	
Be	~~10^{-7}~~ 10^{-6}	
B	$2 \cdot 10^{-6}$	
C	$2 \cdot 10^{-4}$	*
N	-	**
O	2×10^{-3}	***
F	2×10^{-5}	

* Low yield because only C^{13} contributes.
** $(\alpha\text{-}n)$ reaction not energetically possible.
*** Low yield because only O^{17} contributes.
The effect of several impurities simultaneously present is of course additive.

UNCLASSIFIED

It is thus recognized that the preparation and handling of the 49 in such a way as to attain and maintain such high standards of purity is an extremely difficult problem. And it seems very probable that the neutron background will be high and therefore high velocity firing will be desirable.

With 25 the situation is much more favorable. The α's come from 24 present in normal U to about 1/10000. If all 24 goes with 25 in the separation from 28 we shall have 1/100 of 24 in the 25. The lifetime of 24 is 100 times that of 49 so the

SECRET
LIMITED

concentration of impurities in 25 may be 10^4 times that in 49 for the same background, which is not at all difficult of attainment.

To summarize: 49 will be extremely difficult to work with from the stand-point of neutron background whereas 25 without U tamper will be not very difficult.

20. Shooting

We now consider briefly the problem of the actual mechanics of shooting so that the pieces are brought together with a relative velocity of the order of 10^5 cm/sec or more. This is the part of the job about which we know least at present.

One way is to use a sphere and to shoot into it a cylindrical plug made of some active material and some tamper, as in the sketch. This avoids fancy shapes and gives the most favorable shape, for shooting; to the projected piece whose mass would be of the order of 100 lbs.

The highest muzzle velocity available in U. S. Army guns is one whose bore is 4.7 inches and whose barrel is 21 feet long. This gives a 50 lb. projectile a muzzle velocity of 3150 ft/sec. The gun weighs 5 tons. It appears that the ratio of projectile mass to gun mass is about constant for different guns so a 100 lb. projectile would require a gun weighing about 10 tons.

The weight of the gun varies very roughly as the cube of the muzzle velocity hence there is a high premium on using lower velocities of fire.

Another possibility is to use two guns and to fire two projectiles at each other. For the same relative velocity this arrangement requires about 1/8 as much total gun weight. Here the worst difficulty lies in timing the two guns. This can be partly overcome by using an elongated tamper mass and putting all the active material in the projectiles so it does not matter exactly where they meet. We have been told that at present it would be possible to synchronize so the spread in places of impact on various shots would be 2 or 3 feet. One serious restriction imposed by these shooting methods is that the mass of active material that can be gotten together is limited by the fact that each piece separately must be non-explosive. Since the separate pieces are not of the best shape, nor surrounded by the best tamper material, one is not limited to two critical masses for the completed bomb, but might perhaps get as high as four critical masses. However in the two gun scheme, if the final mass is to be $\sim$ 4Mc, each piece separately would probably be explosive as soon as it entered the tamper, and better synchronization would be required. It seems worthwhile to investigate whether present performance might not be improved by a factor ten.

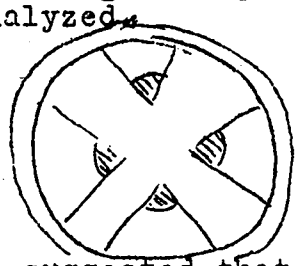
...cument contains information affecting the ... Defense of the United ... S. C. 50-31 and ... of the revelation of its contents ... manner to an unauthorized person is pro-hibited by law.



Severe restrictions on the mass of the bomb can be circumvented by using pieces of shape more difficult to shoot. For example a flat plate of actual material tamped on only one side, has a mimimum thickness below which it can no longer support a chain reaction, no matter how large its area, because of neutron leakage across the untamped surface. If two such plates were slid together, untamped surfaces in contact, the resulting arrangement could be well over the critical thickness for a plate tamped on both sides, and the mass would depend only on the area of the plates.

Calculations show that the critical mass of a well tamped spheroid, whose major axis is five times its minor axis, is only 35% larger than the critical mass of a sphere. If such a spheroid 10 cm thick and 50 cm in diameter were sliced in half, each piece would be sub-critical though the total mass, 250 Kg, is 12 times the critical mass. The efficiency of such an arrangement would be quite good, since the expansion tends to bring the material more and more nearly into a spherical shape.

Thus there are many ordnance questions we would like to have answered. We would like to know how well guns can be synchronized. We shall need information about the possibilities of firing other than cylindrical shapes at lower velocities. Also we shall need to know the mechanical effects of the blast wave preceeding the projectile in the gun barrel. Also whether the projectile can be made to seat itself properly and whether a piston of inactive material may be used to drive the active material into place, this being desirable because thus the active material might be kept out of the gun barrel which to some extent acts as a tamper.

Various other shooting arrangements have been suggested but as yet not carefully analyzed.

For example it has been suggested that the pieces might be mounted on a ring as in the sketch. If explosive material were distributed around the ring and fired the pieces would be blown inward to form a sphere.

Another more likely possibility is to have the sphere assembled but with a wedge of neutron-absorbing material built into it, which on firing would be blown out by an explosive charge causing k to go from less than unity to more than unity. Here the difficulty lies in the fact that no material is known whose absorption coefficient for fast neutrons is much larger than the emission coefficient of the bomb material. Hence the absorbing plug will need to have a volume comparable to that of the absorber and when removed will leave the active material in an unfavorable configuration, equivalent to a low mean density.

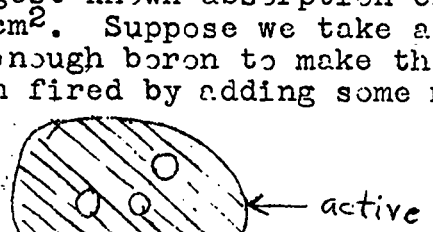
21. Autocatalytic Methods



The term "autocatalytic method" is being used to describe any arrangement in which the motions of material produced by the reaction will act, at least for a time, to increase ν' rather than to decrease it. Evidently if arrangements having this property can be developed they would be very valuable, especially if the tendency toward increasing ν' was possessed to any marked degree.

Suppose we had an arrangement in which for example ν' would increase of its own accord from a low value like 0.01 up to a value 10 to 50 times greater. The firing problem would be simplified by the low initial value of ν', and the efficiency would be maintained by the tendency to develop a high value of ν' as the reaction proceeds. It may be that a method of this kind will be absolutely essential for utilization of 49 owing to the difficulties of high neutron background from (α, n) reactions with the impurities as already discussed.

The simplest scheme which might be autocatalytic is indicated in the sketch where the active material is disposed in a hollow shell. Suppose that when the firing plug is in place one has just the critical mass for this configuration. If as the reaction proceeds the expansion were to proceed only inward it is easy to see from diffusion theory that ν' would increase. Of course in actual fact it will proceed outward (tending to decrease ν') as well as inward and the outward expansion would in reality give the dominant effect. However, even if the outward expansion were very small compared to the inward expansion it has been calculated that this method gives very low efficiency: with 12 Mc an efficiency of only about 10^{-9} was calculated.

A better arrangement is the "boron bubble" scheme. B^{10} has the largest known absorption cross-section for fast neutrons, $1.52 \cdot 10^{-24}$ cm^2. Suppose we take a large mass of active material and put in enough boron to make the mass just critical. The device is then fired by adding some more active material or tamper.

As the reaction proceeds the boron is compressed and is less effective at absorbing neutrons than when not compressed. This can be seen most readily if one considers the case in which the bubbles are large compared to the mean depth in which a neutron goes in boron before being absorbed. Then their effectiveness in removing neutrons will be proportional to their total area and so will drop on compression. Hence ν' will increase as the bubbles are compressed. If the bomb is sufficiently large this tendency is bound to overweigh the opposing one due to the general expansion of the bomb material, since the distance the edge of the bomb must move to produce a given decrease in ν' increases with the radius of the bomb, whereas for a larger bomb the distance the edge of a

APPROVED FOR PUBLIC RELEASE

UNCLASSIFIED

APPROVED FOR PUBLIC RELEASE

SECRET

bubble must move is unchanged, since it is not necessary to increase the radius of the bubbles but only to use more of them.

The density of particles (electrons plus nuclei) in boron is 8.3 x 10^{23} particle/cm^3 while in uranium it is more than 5 times greater. Therefore as soon as the reaction has proceeded to the point where there is a high degree of ionization and the material behaves as a gas there will be a great action to compress the boron. An opposing tendency to the one desired will be the stirring or turbulence acting to mix the boron uniformly with the uniform, but the time scale is too short for this to be effective.

It can be shown that if initially $\nu' = 0$, allowing for the boron absorption, and if no expansion of the outer edge occurs then ν' will rise to $\nu' \sim \frac{1}{4}(\nu - 1)$ by compression of the boron. This scheme requires at least five times the critical mass for no boron, and the efficiency is low unless considerably more is used.

If one uses just that amount of boron which makes twice the no-boron critical mass be just critical, then the efficiency is lower by a factor at least 30.

All autocatalytic schemes that have been thought of so far require large amounts of active material, are low in efficiency unless very large amounts are used, and are dangerous to handle. Some bright ideas are needed.

22. Conclusion

From the preceeding outline we see that the immediate experimental program is largely concerned with measuring the neutron properties of various materials, and with the ordnance problem. It is also necessary to start now studies on techniques for direct experimental determination of critical size and time scale, working with large but sub-critical amounts of active material.

h. Book VIII, Los Alamos Project (Y), deals with all the activities which were carried on at the Los Alamos Laboratories, Los Alamos, New Mexico, including principally: research, design, final processing, construction, assembly and testing of the bombs themselves; site selection and land acquisition; construction, administration and operation of the community, with its housing, utilities, commercial facilities and services; and construction, administration and operation of the so-called technical area and of various outlying, "satellite", sites. This book also tells of numerous other activities which were carried on at other places scattered through the United States, all of which may be regarded as auxiliary to the critical major work at Los Alamos, some of them of very great importance. The technical work at Los Alamos was carried on under contract with the University of California, directed by Dr. J. R. Oppenheimer of that University; the general administration of the community, which was operated as a military post, and all construction work were under the local direction of an Army officer - the Commanding Officer. Major construction work was performed principally, in the earlier days, by M. M. Sundt Construction Company, and then, through successive large expansions, by Robert E. McKee. The Architect-Engineer for most of the design work was W. C. Kruger.

The non-scientific part of the history of the Los Alamos Project is in Volume 1 of Book VIII; the technical part of its history is in Volume 2; and the auxiliary activities are described, in various chapters, in Volume 3.

Of the auxiliary activities, particular mention should be made of: the Los Angeles Procurement Office, which handled most of the

diverse procurement required for all the Los Alamos activities; and the Camel Project, which covered some complex research, testing and production work and served as an emergency reserve in case of catastrophe at Los Alamos. Other important auxiliary subjects described in Volume 3 include: Activities of Ohio State Cryogenic Laboratory; Dayton Project; Navy Participation; Sandia; Boron; Operation Crossroads (in which personnel of the Manhattan District took an important part); and various other miscellaneous activities.

The real climax of the Los Alamos Project - indeed, the real climax of the whole of the Manhattan Project - is described in the "Technical" volume of this book. This was the so-called Trinity Test, the first man-made atomic bomb explosion of all time, which took place in the desert at Alamogordo Air Base, New Mexico, on 16 July 1945. Not until that test was successfully made could anyone connected with the enterprise be sure that the project would produce any concrete results.

The official climax of the Manhattan Project - the official culmination of the years of effort of thousands of people and of the expenditure of about two billions of dollars - was the combat bombing of Japan, at Hiroshima and Nagasaki, in August 1945. This also is described in the "Technical" Volume (Vol. 2) of Book VIII, in a chapter headed: "Project Alberta".

RESTRICTED DATA
ATOMIC ENERGY ACT 1946

SECTION 2 - THE MISSION OF THE MANHATTAN DISTRICT

2-1. The District's Mission, in Simplest Terms - Reduced to its simplest terms, the mission of the Manhattan District was to develop and manufacture atomic bombs for combat use, at the earliest possible date, and ahead of the enemy, in order to help the United States and its Allies to bring World War II to a successful conclusion with the least delay and the greatest possible conservation of life.

2-2. Justification - The world's history during the first few weeks following the dropping of the first combat bomb on Hiroshima on 6 August 1945 proved conclusively not only that this mission of the Manhattan District was successfully accomplished but also that this mission - with its accompanying expenditure of about two billions of dollars - was completely justified.

a. One phase of this justification has been described impressively by Major General L. R. Groves, in a public address given in June 1946, in the following words:

"....While the mission was to develop the atomic bomb, the real objective was to save the lives of thousands of America's best men - by shortening the war.

"The war was not won by the atomic bomb. It was won by our fighting men, backed up by the best of weapons provided for them by the industrial might of the nation. The Japanese had lost the war long before the Hiroshima bombing, but the people did not know it, and their leaders did not admit it. Both people and leaders knew it and admitted it within a few hours after they learned of Hiroshima.

~~RESTRICTED DATA~~ ATOMIC ENERGY ACT 1946

"I believe the historians of the future will be unanimous in the conclusion that the atomic bomb ended the war in a more abrupt and sudden manner than any war has been ended since the day of that other great surprise weapon, the Trojan Horse.

"Let us look for a moment at the timetable of last summer. On the 16th of July, the first atomic bomb test occurred in New Mexico. News of the successful results were rushed to President Truman, then in Potsdam, and in a few days, - on the 26th, to be exact - the Potsdam surrender ultimatum was sent to Japan, warning her that unless she surrendered she would be destroyed.

"On the 29th, Radio Tokyo broadcast that the Japanese Premier scorned the Allied warning as 'unworthy of public notice.' Eight days later, Hiroshima was hit by the first atomic bomb. We told the government and the people of Japan what had hit them. That was August 6, 1945. Two days later, Russia hurriedly entered the war against Japan. The next day, the second atomic bomb fell on Nagasaki. On the tenth of August, the Swiss Charge d'Affaires in Washington sent a note to our Secretary of State, stating that the Japanese government was ready to accept the terms of the Potsdam Ultimatum. On the 14th, after almost four years of unremitting war and eight days after the first atomic bomb was dropped, the Japanese government unconditionally surrendered.

"The men scheduled to enter Japan the hard way - across the beaches - and their mothers and fathers, wives and children, soon realized that they had had an infinite stake in the two billion dollar program which had been such a closely guarded secret for more than three years . . ."

PREFACE

The technical history for Project Y, from its inception until August 1945, has been recorded in Book VIII, Volume 2. It is the purpose of this work to present the activities of the Los Alamos Laboratory from August 1945 until the end of December 1946, when the Manhattan District relinquished its control. No attempt has been made to interpret events, or to forecast the importance of scientific developments during this period. This book is merely a chronicle of the reorganization, philosophy and subsequent achievements which transpired in this critical interim period following the cessation of hostilities.

It will be noted that this supplement is treated as an individual book and that for the sake of consistency, it follows the mechanical arrangement used in the basic volume. This system deviates somewhat from the established standard for the Manhattan District histories, in its method of paragraphing, duplication, indexing and size. Approval for this deviation was granted for both the basic work and its supplement.

The method of cross reference employed in this book requires some explanation. Whenever an allusion is made to material within the supplemental volume, only the paragraph number is used as a parenthetical reference, e.g., (par. 1.23). However, to avoid confusion when reference is made to another volume of the Los Alamos History, a full description follows, e.g., (Book VIII, Vol. 1, par. 4.34).

Historical material for this supplement came from the Director, Dr. N. E. Bradbury, the Administrative Associate Director, Lt. Col. A. W. Betts, the seven Technical Division Leaders: Carson Mark, J. M. B. Kellogg, Marshall Holloway, Eric Jette, Max Roy, R. W. Henderson, and Ralph Carlisle Smith. Further assistance was rendered by J. F. Mullaney, Report Editor, and A. E. Dyhre,

1.37 The basic design of a "composite" implosion weapon using both plutonium and uranium 235 was developed for use under implosion conditions similar to those previously employed for pure plutonium. (par. 3.17)

Crossroads Operation

1.38 In December 1945, the laboratory was informed that a test of atomic weapons against naval vessels was proposed, and the laboratory was requested to undertake the technical direction of this test as well as to supply the atomic weapons to be used therein. Preliminary meetings were held in December 1945 and January 1946, during the course of which it was decided to:

1. Set up a Joint Task Force Operation with the Army, Navy, and Manhattan Engineer District.

2. To employ the same type of atomic weapon as used at Nagasaki.

3. To recommend three types of test to be conducted in the order given below:

Able: Air burst over an array of representative ships.

Baker: Shallow water burst under an array of representative ships.

Charlie: Deep water burst under an array of representative ships.

1.39 The atoll of Bikini in the Marshall Islands was selected by the Navy as a satisfactory location for tests "Able" and "Baker" with possibility that test "Charlie" might be conducted on the deep water side of the atoll.

1.40 The laboratory selected Dr. Ralph A. Sawyer as Technical Director for this operation, with Dr. Marshall Holloway (B-Division) and Mr. Roger Warner (Z-Division) under him as heads of the Los Alamos experimental groups and weapon preparation groups respectively.

3. The McNierney Cattle Case

2.104 On August 25, 1946, $1,350 was paid by the University to Mr. W. L. McNierney as compensation for loss suffered by him in connection with the sale of 140 head of cattle at reduced market value during September 1945 as the result of discoloration of cattle hair alleged to have been caused by exposure during the test at Alamogordo, New Mexico, on July 16, 1945.

4. Telephone and Telegraph

2.105 For reasons of security, payment of telephone and telegraph services was handled through the Business Office. All bills from Western Union, Railway Express (which handled much of the telegraphic service in order to assist us in maintaining security) and from the telephone company were billed to the Business Office, that office in turn collecting the amounts due from the various employees. This practice was discontinued as of the last of May 1946 after the relaxing of security regulations, inasmuch as it was then deemed safe to establish such accounts in individual names of employees at the Project.

5. Nursery School

2.106 Financing of the nursery school was handled by the University through the Business Office. It was the duty of that office to collect from the parents of the children enrolled, the tuition and the fees for lunches served. The Business Office in turn paid the school teachers, the food bills, maid service, dietician and other bills. Such services as nurse, janitor, utilities, buildings and laundry were not chargeable to the budget but were subsidized by the Government. The school continued as a responsibility of the Business Office until December 1, 1946, at which time it was directed by Colonel A. C. Nauman, in his letters of October 30, 1946, and November 25, 1946, that responsibility for operation of the nursery school (a part of Community Services) would be assumed by the Zia Company effective December 1, 1946.

6. Newspaper

2.107 As of June 21, 1946, the local newspaper, the Los Alamos Times,

Chapter III

THEORETICAL PHYSICS DIVISION

Introduction

3.1 During the third period, August 1945 through the year 1946, the Theoretical Division continued its war-time program with certain modifications and on a reduced scale, and added to its interests the theoretical-physics research on thermonuclear systems formerly carried on in F Division (Book VIII, Vol. 2, par. 13.3). In the fall of 1945, much attention was given to the complex hydrodynamical problems involved in the interpretation of the blast measurements made at Trinity and at Hiroshima and Nagasaki; also, during this time, much effort was spent on the radiation hydrodynamics of the implosion fission bomb, largely because of the unexpectedly high efficiency of this weapon.

Organization

3.2 The difficulties of the early interim period affected Theoretical Division seriously. Of the Division Leader and the eight group leaders serving in August 1945, all had left by September 1946; early in this period most of the junior members of the division returned to the universities to resume their interrupted studies. The group structure of the division in August 1945, together with the date of termination of regular employment of the group leader, was as follows:

Group		Group Leader	Termination of Regular Employment
T-1	Implosion Dynamics	R. E. Peierls	January 1946
T-2	Diffusion Theory	R. Serber	November 1945
T-3	Efficiency Theory	V. F. Weisskopf	February 1946
T-4	Diffusion Problems	R. P. Feynman	October 1945
T-5	Computation	D. A. Flanders	September 1946
T-6	IBM Computations	E. Nelson	January 1946
T-7	Damage	J. O. Hirschfelder	August 1946
T-8	Composite Weapon	G. Placzek	May 1946

Many of the above-named group leaders were retained in consultant status.

SECRET RD

3.3 On 14 November 1945, Group F-1, which had been part of Theoretical Division up to June 1944 (Book VIII, Vol. 2, par. 13.3), returned to Theoretical Division and became Group T-7. As before, its concern was the theory of thermonuclear systems.

3.4 On 1 December 1945, Hans A. Bethe resigned as Theoretical Division Leader and shortly thereafter returned to his position at Cornell University. His successor was George Placzek, who had joined the Theoretical Division in May 1945 after working for several years with the Montreal group.

3.5 Early in 1946, a general reorganization took place, and the resulting group structure on 8 January 1946 was as follows:

Group		Group Leader	Termination of Regular Employment of Group Leader
T-1	Hydrodynamics	Joseph M. Keller	27 June 1946
T-2	(Group dissolved; personnel transferred to T-8)		
T-3	Efficiency Theory	V. F. Weisskopf	28 February 1946
T-4	Diffusion Problems	R. Ehrlich	9 January 1946
T-5	Computations	D. A. Flanders	4 September 1946
T-6	IBM Computations	R. W. Hamming	24 June 1946
T-7	Super	E. Teller	21 January 1946
T-8	Diffusion Theory	C. Mark	Did Not Terminate

3.6 The return of key personnel to the universities for the spring semester in 1946 necessitated considerable change. Groups T-2, T-3, and T-4 were dissolved and the personnel were transferred to the remaining groups.

3.7 Work on radiation hydrodynamics formerly carried on by Group T-3 became the concern of R. Landshoff, a member of Group T-7, who in May 1946 visited Ithaca, Rochester and Boston to discuss this work with former members of Group T-3. Group T-1 was dissolved in June; some of the problems worked on by this group were distributed among the remaining groups. A new group, T-1, was formed under the leadership of F. Reines to consider the theory of the dragon (par. 3.38) and to

work on blast wave and damage problems which might arise. All computations, both manual and machine (IBM), became the concern of a group under D. A. Flanders. In anticipation of Mr. Flanders' leaving, B. Carlson became group leader of a new group, T-2, on 14 August 1946.

3.8 Operation Crossroads, which seriously affected the work of some other divisions, did not add to the personnel problems of T-Division. J. O. Hirschfelder, and J. L. Magee, both of whom were with Group T-7 (Damage) until their resignations in the fall of 1945, returned to devote full-time attention to Operation Crossroads problems in the spring and summer of 1946.

3.9 On 20 May 1946, G. Placzek became ill and left Los Alamos on a leave of absence. He could not return to the Project because the high altitude affected his unfavorable heart condition; however, he was not terminated until 9 July 1946. Robert D. Richtmyer, who had transferred from the Patent Group, acted as Division Leader for the Theoretical Division until November 1946 when he became Division Leader.

3.10 In the summer of 1946 a group of consultants aided the work of Theoretical Division. This group included E. Fermi, F. Hoyt, and E. Teller of the University of Chicago; Lothar Nordheim and Gertrud Nordheim of Clinton Laboratories; R. Marshak of the University of Rochester; R. P. Feynman of Cornell University; J. O. Hirschfelder, University of Wisconsin; J. Von Neumann, of the Institute of Advanced Studies, Princeton University; V. Weisskopf, T. Welton, of the Massachusetts Institute of Technology.
With the exceptions of Mr. and Mrs. Nordheim and Mr. Hoyt, all were members of the wartime staff of Los Alamos.

3.11 In the Fall of 1946, S. Ulam, who left Group F-1 in 1945 to join the staff of the University of Southern California, returned to Los Alamos to become Group Leader of a new group whose concern was general mathematical methods. L. Goldstein, formerly of the College of City of New York, and the Division of War

Research, Columbia University, joined the T Division Staff at about the same time.

3.12 A group was set up in the Fall of 1946 under the leadership of R. D. Richtmyer to study the new thermonuclear system proposed by E. Teller, known as the "Alarm Clock" (par. 3.32).

3.13 The group structure of Theoretical Division at the close of the third period, December 1946, was as follows:

T-1	Theory of Dragon	F. Reines
T-2	Computations	B. Carlson
T-3	Super and Radiation Hydrodynamics	R. Landshoff
T-4	Diffusion Theory	C. Mark
T-5	IBM Computations	B. Carlson (Acting)
T-6	Mathematical Methods	S. Ulam
T-9	Alarm Clock	R. D. Richtmyer
T-10	Fundamental Nuclear Physics	L. Goldstein

Effects of Test and Combat Nuclear Explosions

3.14 Interpretation of observations of the July 16, 1945 test explosion at Trinity and of the combat explosions at Hiroshima and Nagasaki made up much of the activity of Theoretical Division in the early fall of 1945. A theory was developed by Group T-1 (Appendix 10,No.10) for estimating the energy release of a fission bomb explosion by consideration of the expansion velocity of the ball of fire in its early stages; this theoretical treatment differed from earlier ones in that it considered the effect of the high-density material of the bomb (and at Trinity, its supporting platform and housing) on the pressure distribution. In an attempt to eliminate the uncertainty (Book VIII, Vol. 2, par. 11.26 concerning the proportion of energy released by a fission bomb which is converted into blast energy, a calculation (Problem M) using the IBM machines was made; the blast energy resulting from the explosion of a fission bomb was found to be about two-thirds that resulting from the explosion of a corresponding amount of TNT

(Appendix 10,No. 11). The final analysis by Group T-1 of the blast and optical data (Appendix 10,No.12) gave as the most probable values based on these data for the nuclear energy release the TNT equivalents of 20,000 tons for Trinity, 15,000 tons for Hiroshima, and 50,000 tons for Nagasaki; the value for Nagasaki was more uncertain than the others.

Radiation Hydrodynamics

3.15 The unexpectedly high yield of the Trinity explosion (Book VIII, Vol. 2, par. 11.27) led to a renewal of the early speculations (Book VIII, Vol. 2, pars. 5.43 to 5.45) about the simplifying assumption (Book VIII, Vol. 2, par. 5.37) of neglect of radiation made in the original efficiency calculations.

Super

3.19 At the close of the war, Group F-1 (which became Group T-7 on 14 November 1945) was relieved of its responsibilities connected with the design and testing of fission bombs and was able to devote full-time attention to bombs based on thermonuclear processes. E. Fermi summed up existing knowledge on relevent thermonuclear processes in a series of six lectures given in July, August and September 1946. (Appendix 10,No.17) The period of intensive activity of this group came to an end by June of 1946 when the work was curtailed through serious

loss of personnel.

Super Conference

3.20 In April 1946, a conference of members of Group T-7 and other Los Alamos staff members and consultants concerned with the development of thermonuclear bombs took place (par. 1.21). The work on thermonuclear processes was reviewed, and a specific model of a thermonuclear bomb was considered.

3.21 An account of the fundamental physical processes of importance to the thermonuclear bomb is presented in Book VIII, Vol. 2, pars. 13.6 through 13.17, and will not be repeated here. The conference, although it examined this fundamental work for completeness and accuracy, centered its attention on the feasibility of the specific model presented by Group T-7. Proposals and suggestions regarding basic theoretical investigations grew from examination and consideration of this model, which must be described in some detail before reporting the conclusions reached in the conference.

3.22 The model proposed was chosen for amenability to theoretical treatment rather than for engineering practicability or efficient use of precious material. This followed from the purpose of the conference, which was to study the feasibility of thermonuclear bombs in principle, and not to propose designs for actual weapons.

DOE b (1)

3.23 Consideration of fundamental principles indicated the operability of a large class of designs having in common the following features:

DELETED DELETED

DELETED DELETED

DOE (b)(3)

DELETED DELETED

DELETED DELETED

Various suggestions were made for means to improve the efficiency of use of tritium and fissionable material and to simplify the engineering of the weapon. But no objection on fundamental grounds to the feasibility of a thermonuclear bomb was presented.

3.27 The members of the conference estimated that the experimental program, development, and testing of the thermonuclear super bomb would require work by a laboratory similar to Los Alamos at its wartime peak for a period of the order of one or two years.

DOE (b)

3.28 Following a recommendation of the conference, Group T-7, soon renamed Group T-3, started a theoretical investigation

DELETED DELETED DELETED

This work proceeded throughout the spring and summer of 1946, although it was hampered greatly by shortage of personnel.

DOE (b)

DELETED DELETED

DELETED DELETED

DOE b(3)

DELETED DELETED

DELETED DELETED

3.31 By the fall of 1946, continuing loss of personnel and the need for continuing work on radiation hydrodynamics, which was another interest of Group T-3, further curtailed work. In addition, the need for evaluating a new thermonuclear system described below further diluted the efforts of the remaining personnel.

"Alarm Clock"-Thermonuclear System

3.32 In September 1946, E. Teller described a new proposed thermonuclear system incorporating several novel features:

DOE b(3)

before (Chapter I) prevented the Director from giving these staff functions any considerable time, hence, the groups tended to lose their effectiveness.

Formation of D-Division

9.4 When Major Ralph Carlisle Smith, the local Patent Advisor, returned from his security and technical advisory assignment to the Operations Crossroad press ship, U.S.S. Appalachian, he was requested by the Director to consolidate the technical staff groups, other than the health group, into a division, and ultimately to take over the duties of an Assistant Director. On 21 August 1946, the Director announced the formation of the Documentary (D) Division with the responsibility for Technical Series editorial work; the Document Room; the Technical Library; editorial revision, review and control of reports; information dissemination; declassification; history; and various other technical services, with Major Ralph Carlisle Smith as Head and Herbert I. Miller as alternate. (Appendix 10, No. 29) Although the contractor did not assume responsibility for Patent control, this being the delegated responsibility to Smith from the OSRD Patent Advisor, Captain R. A. Lavender, U.S.N. Ret., this control was exercised in the Documentary Division as a dual responsibility of its leader. Later when Mr. E. J. Demson left the project in 1946, Major R. C. Smith also accepted the project responsibilities of an Assistant Director, particularly the legal duties of Mr. Demson. This new arrangement removed a considerable load from the Director and by reorganization of the accumulated staff groups, so as to use the available professional personnel in several phases of the work, it was possible to improve the services of the staff groups with a smaller number of employees. The responsibilities were generally divided as follows: Patents and Legal, Library and Document Room, History and Technical Series, Report Editing - Review, Classified Information Dissemination, Declassification, Drafting (Patents, Reports and Miscellaneous), Technical Illustrations and Art Work.

9.5 The group organization for D-Division during 1946 is shown in Appendix 8A.

9.6 Most of the functions of D-Division have been covered in the discussion under the technical staff groups of **Book VIII**, Vol. 2, par. 3.82 to 3.87 and 3.123 to 3.128. There are few phases however which are new and which merit additional comment.

THE TECHNICAL SERIES

9.7 In conformity with other sections of the Manhattan Project, a program was initiated to record, in accessible and edited form, the technical knowledge and gains of the laboratory. In principle, it was proposed to prepare a "Handbuch der Los Alamos" in analogy with the famous Handbuch der Physik (Appendix 10, No. 30). Titles for seventeen volumes were established in August 1945, as well as volume, and, in some cases, chapter and section editors. Difficulty in establishing a title for the overall work arose. The original name "Handbuch der Los Alamos" was misleading in its English translation, so the title Los Alamos Encyclopedia was substituted. But inasmuch as it was decided that "encyclopedia" implied an alphabetical arrangement, that too was discarded and the "Los Alamos Technical Series" was finally chosen. (Appendix 8B).

9.8 Dr. Hans Bethe and Dr. David Inglis were originally responsible for this compilation with the following staff of volume editors:

Volume No.	Title	Editor
0	"Relation Between the Various Activities of the Laboratory"	S. K. Allison
1	"Experimental Techniques"	Darol K. Froman
2	"Numerical Methods"	Eldred C. Nelson
3	"Nuclear Physics"	R. R. Wilson
4	"Neutron Diffusion Theory"	George Placzek
5	"Critical Assemblies"	O. R. Frisch
6	"Efficiency"	V. F. Weisskopf

7	"Blast Wave"	Hans. A. Bethe
8	"Chemistry of Uranium and Plutonium"	Joseph Kennedy
10	"Metallurgy"	Cyril S. Smith
11	"Explosives"	G. B. Kistiakowsky
12	"Implosion"	R. F. Bacher
13	"Theory of Implosion"	R. E. Peierls
21	"The Gun"	F. Birch
22	"Fuzes"	R. R. Brode
23	"Engineering and Delivery"	N. F. Ramsey
24	"Trinity"	K. T. Bainbridge

9.9 Only Volume 1 and 2 have been considered completely declassifiable under the existing standards. However, a substantial portion of the information in some of the others will eventually be declassifiable and, with the exception of the weapon data, the remainder was to be distributable throughout the Manhattan Project for its general benefit.

9.10 Shortly after the initiation of the program, Dr. David Hawkins and Robert R. Davis were assigned the responsibilities of the Technical Series because of the imminent departure from Los Alamos of both Dr. Bethe and Dr. Inglis. When Dr. Hawkins left the project in the late summer of 1946, Robert R. Davis took over the detail as a Group Leader in D-Division.

9.11 The Technical Series compilation has proceeded at a slow rate since the time of its inception. Exceptional delays resulted because many individuals were reluctant or unable to continue obligations, taken on while at Los Alamos, after their departure. A more understandable difficulty was experienced by active project personnel who were faced with the problem of conducting an active technical program while writing about one accomplished in the past.

9.12 By January 1947, Vol. 0 and 22 were completed and issued, and two-thirds of Vol. 1 had been issued.

Appendix Number 7

Description of Technical Series

Title and brief description of each volume being written for the Los Alamos Technical Series. (par. 9.7).

CONTENTS OF THE LOS ALAMOS TECHNICAL SERIES

Volume Number	Title and Description	Editor
0	"Relation Between the Various Activities of the Laboratory" (A general survey of the work of the Los Alamos Laboratory during the war years, with particular emphasis upon the problems of the critical mass and of the efficiency. In addition to a discussion of the gun and implosion type bombs, the volume contains a section dealing with other methods of attaining the explosive release of nuclear energy.)	S. K. Allison
I	"Experimental Techniques" (A description of the experimental physics equipment used by the Los Alamos Laboratory. The volume has three parts: the first dealing with electronics; the second with ionization chambers and counters; and the third with miscellaneous techniques used in obtaining physical measurements.)	Darol K. Froman
II	"Numerical Methods" (A survey of the methods used in performing numerical calculations of various types of equations by hand computation and with the use of International Business Machines.)	Mildred C. Nelson
III	"Nuclear Physics" (A comprehensive report of nuclear physics measurements made by the Los Alamos Laboratory, together with theoretical evaluations of results and a detailed discussion of the fission process.)	R. R. Wilson
IV	"Neutron Diffusion Theory" (The theory of diffusion with and without a change in velocity, including a discussion of statistical fluctuations.)	George Placzek

SECRET RD

Volume Number	Title and Description	Editor
V	"Critical Assemblies"	O. R. Frisch
	(A report of critical mass experiments made at Los Alamos with uranium-235 and plutonium assemblies for various tampers. A theoretical discussion is included.)	
VI	"Efficiency"	V. F. Weisskopf
	(A theoretical method for calculating the energy release of a nuclear explosion.)	
VII	"Blast Wave"	Hans A. Bethe
	(A study of blast wave phenomenon, both from a theoretical and an experimental point of view. Particular emphasis is placed upon the behavior of the blast wave in large explosions, and an effort has been made to interpret blast data from studies made at Trinity, Hiroshima and Nagasaki.)	
VIII	"Chemistry of Uranium and Plutonium"	Joseph Kennedy
	(A survey of the problems concerned with the chemical purification and recovery of uranium and plutonium, together with a discussion of the preparation of their various compounds and of the analytical methods used in their study.)	
X	"Metallurgy"	Cyril S. Smith
	(A report on the metallurgy of uranium, plutonium and all other metals fabricated by the CMR Division.)	
XI	"Explosives"	G. B. Kistiakowsky
	(A survey of the experimental work done by the Los Alamos Laboratory on the behavior of explosives and on the techniques of explosive casting.)	

SECRET RD

~~SECRET~~ RD

Volume Number	Title and Description	Editor
XII	"Implosion"	R. F. Bacher
	(A report on the experimental implosion program from the early tests to the development of the Trinity bomb. The volume covers work done on polonium, radio-barium and radio-lanthanum.)	
XIII	"Theory of Implosion"	R. E. Peierls
	(A theoretical survey of the implosion process. The volume contains discussions of shock hydrodynamics, equations of state and various implosion designs.)	
XXI	"The Gun"	F. Birch
	(A survey of the experimental gun program from the early tests to the development of the Hiroshima bomb. This volume includes design specifications and a discussion of the interior ballistics of the gun.)	
XXII	"Fuzes"	R. B. Brode
	(A study of work done by the Los Alamos Laboratory in designing detonating fuze assemblies for the implosion and gun type bombs.)	
XXIII	"Engineering and Delivery"	N. F. Ramsey
	(The history of Project "A" together with a discussion of engineering problems encountered in the delivery program. Particular attention has been given to the mechanical design and assembly of the Model 1561 implosion bomb.)	
XIV	"Trinity"	K. T. Bainbridge
	(A complete report on the 100 ton TNT calibration and rehearsel shot and the July 16, 1945 atomic bomb test at the Alamogordo Air Base. The volume includes both experimental and theoretical discussions of the various phases of the test. A large appendix contains all pertinent Trinity memoranda and all LA and LAMS reports concerning the Trinity explosion.)

PREFACE

Project Y, the Los Alamos Project, has been one of a group of organizations known collectively as the Development of Substitute Materials Project, devoted to the wartime development of the atomic bomb. This branch of the DSM organization was created early in the year 1943. During the period of its existence it has been the center of activities connected with bomb development and production, as distinguished from the development and production of nuclear explosive materials.

The history of all DSM activities possesses a peculiar interest and importance, not only because of the remarkable achievements and potentialities of nuclear technology, but also because of the wartime character and motivation of its initial development. Because of its large social cost, a scrupulous accounting of the entire venture is evidently required. Project Y has been, of itself, small compared to the other DSM projects. It has, however, occupied a crucial position. The wartime success of the entire undertaking has depended upon its success.

The nature of the present chronicle of Los Alamos is thus determined by the requirement that there exist a careful accounting of its technical, administrative and policy-making activities. This document is a record, not an interpretation of events. Within the limitations thus implied, however, it has not been forgotten that the events recorded have taken place within a wider context, the evolution of organized scientific research and of world technology. The problems of organization and policy that lie here, sharpened by the advent of control over nuclear energies, will call for the most searching interpretation and analysis. It is hoped that in this record of fact

it does come at the time of an extensive administration reorganization. The real purpose of this division is to permit some chance to summarize and connect activities which, although constantly interrelated in practice, must be written about in separate chapters. And although no distinct separation into phases is possible, the date chosen marks as well as any the transition at Los Alamos from research to development, from schematization to engineering.

At this place I wish to acknowledge the assistance I have received from many members of the Los Alamos Laboratory. In particular I wish to thank the following: Major J. A. Ackerman, S. K. Allison, E. Anderson, K. T. Bainbridge, C. L. Critchfield, P. Duffield, A. C. Graves, E. Graves, L. H. Hempelmann, T/4 A. U. Henshey, H. I. Miller, E. Morrison, P. Morrison, N. H. Ramsey, F. Reines, Major Ralph Carlisle Smith, and R. Taschek. These persons have materially helped me in gathering data, in drafting various sections of the report, or in extensive criticism of earlier drafts. I wish especially to thank Emily Morrison and Priscilla Duffield for ingenious researches in the records of an organization that was frequently too busy to be concerned with posterity. Mrs. Morrison has prepared the graphical material, has drafted several of the chapters, and has given invaluable general assistance. Finally it must be made clear that all errors of fact in this record are the sole responsibility of the author.

David Hawkins

scattering is not isotropic, it is also necessary to specify the angular distribution of scattered neutrons. All of these cross-sections, moreover, depend upon the nucleus involved and the energy of the incident neutron. Calculation of critical mass and efficiency depends upon all of these cross sections, as well as upon the number of neutrons per fission and density of material. It was clear that to obtain such measurements with the necessary accuracy would entail an elaborate program of experimental physics and a comparable effort of theoretical physics to make the best use of information obtained.

1.37 Effects of Tamper. The effect of tamper is not only to decrease the critical mass by reflecting neutrons back into the active material, but also to increase the inertia of the system and therefore the time during which it will remain in a supercritical state. These gains are somewhat lessened by the longer time between fissions of neutrons reflected back from the tamper. The lengthening of the time is caused not only by the longer path, but also by a loss of energy through inelastic scattering in the tamper. Calculations of the effect of tamper material depend thus on the absorption and scattering cross-sections of tamper material. It is interesting to note that Serber's early calculations gave, for a tamper of U^{238}, a critical mass for U^{235} of 15 kilograms, and for Pu^{239} of 5 kilograms. Both figures are correct to within a reasonable error. This may be regarded as in part good fortune, since many of the assumptions made were rough guesses. It nevertheless serves to illustrate the advanced state of basic theory at the time.

1.38 Efficiency, Detonation and Predetonation. Some indication has been given above of the basis for efficiency calculations. The outcome of such calculations was to show that efficiencies would be low. There is, moreover, another essential factor in efficiency, connected with the problem of assembly and detonation, the early discussion of which is reviewed below.

DOE b(3)

that are involved.

DELETED DELETED DELETED

1.41 Gun Assembly, Initiator. The considerations of the last section indicate the magnitude of the assembly problem: to initiate properly and reliably a reaction whose entire course occurs in a fraction of a microsecond, subject to the complementary needs for high-velocity assembly and low neutron background. As was mentioned above, the principal source of neutron background is the (α, n) reaction in light-element impurities. To lower this background would require a strenuous program of chemical purification.

1.42 The most straightforward early proposal for meeting these difficulties was the method of gun assembly; the general proposal was that a projectile of active and tamper material, or of active material alone, be shot through or laterally past a target of active material and tamper. For U^{235} both the chemical purity requirements and the needed velocity of assembly were attainable by known methods. Many difficult engineering problems were evidently involved, but they did not appear as insuperable. For Pu^{239} the requirements for purity and speed were both somewhat beyond the established range. It seemed, however, that by rather heroic means they could be met.

1.43 High-velocity assembly and the reduction of the neutron background would decrease the probability of predetonation; they would also decrease the probability of detonation at the desired time. Unless material could be assembled so as to remain in its optimum configuration for a considerable length of time, there was a danger that "postdetonation" too would give low efficiency, or that the system would pass through its supercritical state without detonation occurring at

all. To overcome this difficulty it would be necessary to develop a strong neutron source that could be turned on at the right moment. Theoretically feasible schemes for such an initiator had been conceived, but their practicability was not assured.

1.44 Autocatalysis, Implosion. Two other methods of assembly had been proposed, and it was a part of the early program to investigate them. One of these was a self-assembling or autocatalytic method, operating by the compression or expulsion of neutron absorbers during the reaction. Calculation showed that this method as it stood would require large quantities of material and would give only very low efficiencies.

1.45 The second alternative method was that of implosion. In its first concrete form the proposal was to blow together a subcritical hollow spherical shell of active material and tamper by detonation of a surrounding layer of high explosive.

1.46 Both these methods had the great disadvantage, in a short-term war program, of being mere proposals, without any previous engineering implementation such as existed in the field of gun design.

1.47 The Deuterium Bomb or "Super". There existed, at the time of the April Conference, one other important proposal to which considerable thought and discussion had been given in the previous months. This was a proposal to use the fission bomb as a means for initiating a nuclear reaction of a different type from that involved in the fissioning of heavy-element nuclei. Fissioning, the disruption of nuclei with liberation of energy, is a somewhat anomalous reaction restricted to the heaviest nuclei. Among the lighter elements the typical exoergic (energy-producing) reaction is the building up of heavier nuclei from lighter ones. For example two deuterium (hydrogen^2) nuclei may combine to form a helium^3 nucleus and a neutron, or a tritium nucleus (hydrogen^3) and a proton. The energy that is liberated goes into kinetic energy and radiation. If such a reaction occurs in a

mass of deuterium, it will spread under conditions similar to those that control ordinary thermochemical reactions. Hence the reaction is called thermonuclear. The cross-section for a reaction between two deuterium nuclei is strongly dependent upon the energy of the nuclei. At low energies the probability that the reaction will occur is very small. As the temperature of the material increases, the reaction becomes more probable. Finally a critical temperature is reached, where the nuclear reactions in the material just compensate for various kinds of energy loss, such as heat conduction and radiation. The thermonuclear reaction is in detail more complicated than has been indicated, because of the presence of a variety of secondary reactions.

1.48 Among available materials, deuterium has the lowest ignition temperature. This temperature was estimated to be about 35 kilovolts (about 400 million degrees), and is actually somewhat lower. Once ignited, deuterium is about 5 times as energy-productive per unit mass as U^{235}. Thus one kilogram of deuterium equals about 85,000 tons of TNT equivalent. Since it is not more difficult to ignite a large than a small mass of deuterium, and since it is more cheaply produced in usable form than either U^{235} or Pu^{239}, the proposed weapon, using a fission bomb as a detonator and deuterium as explosive, could properly be called an atomic super-bomb. The development of this super-bomb was perforce secondary to that of the fission bomb; on the other hand its potentialities were so great that research toward its development could not be completely neglected.

1.49 It should be mentioned at this point that in the early period of the project the most careful attention was given to the possibility that a thermonuclear reaction might be initiated in light elements of the Earth's atmosphere or crust. The easiest reaction to initiate, if any, was found to be a reaction between nitrogen nuclei in the atmosphere. It was assumed that only the most energetic of several possible reactions would occur, and that the reaction cross-sections were at the maximum values theoretically possible. Calculation led

to the result that no matter how high the temperature, energy loss would exceed energy production by a reasonable factor. At an assumed temperature of three million electron volts the reaction failed to be self-propagating by a factor of sixty. This temperature exceeded the calculated initial temperature of the deuterium reaction by a factor of one hundred, and that of the fission bomb by a larger factor.

1.50 The impossibility of igniting the atmosphere was thus assured by science and common sense. The essential factors in these calculations, the Coulomb forces of the nucleus, are among the best understood phenomena of modern physics. The philosophic possibility of destroying the earth, associated with the theoretical convertibility of mass into energy, remains. The thermonuclear reaction, which is the only method now known by which such a catastrophe could occur, is evidently ruled out. The general stability of matter in the observable universe argues against it. Further knowledge of the nature of the great stellar explosions, novae and supernovae, will throw light on these questions. In the almost complete absence of real knowledge, it is generally believed that the tremendous energy of these explosions is of gravitational rather than nuclear origin.

1.51 More immediate and less spectacular global dangers to humanity arise from the use of thermonuclear bombs, or even fission bombs, in war: principally from the possible magnitude of destruction and from radioactive poisoning of the atmosphere (13-29).

1.52 Damage. So far we have reviewed only the early discussion of energy release. Since, however, the purpose of the project was to produce an effective weapon, it was necessary to compare the atomic bomb with ordinary bombs, not merely as to energy release, but more concretely as to destructive effects. Damage could be classified under several headings: The psychological effects of the use of such a weapon; the physiological effects of the neutrons, radioactive material and radiation produced; the mechanical destruction produced by the

shock-wave of the explosion. Estimation of the first was not of course within the means or jurisdiction of the project. Of the second, it was estimated that lethal effects might be expected within a radius of one thousand yards of the bomb. The radioactivity remaining might be expected to render the locality of the explosion uninhabitable for a considerable period, although this effect would depend on the percentage of activity left behind, which was as yet an unknown quantity. The principal damage would be caused by the mechanical effects of the explosion. These effects were difficult to estimate. Some rough data on the effects of large explosive disasters were available. More reliable information was available concerning the effects of small high explosive bombs, but it was not known for sure how these effects should be scaled upward for high-energy atomic bombs. Serber's report gives an estimate of a destruction radius of about two miles for a 100,000 ton bomb. Members of the British mission who came to the project somewhat later were able to add to the understanding of this topic from their national experience and their research of recent years.

DEVELOPMENT OF PROGRAM

Introduction

1.53 From the previous outline of the state of knowledge at the beginning of the Bomb Project, it is clear that the greatest problems were bound to arise on the side of development and engineering. There was still much work to be done in nuclear physics proper, but enough was known to eliminate great uncertainties from this side of the picture. It should not be concluded, however, that the stage of research was past its prime, to be dominated in turn by problems of application. The normal meanings attached to "research", "development", and "engineering" are altered in the context of wartime science generally; that is particularly true of the Atomic Bomb Project. Two features have determined its general character. The first is the domination of research schedules by production schedules; the second is the nature of the weapon itself. Time schedules for the

production of U^{235} and Pu^{239} were such that the laboratory had before it about two years until explosive amounts of these materials would be available. After that time every month's delay had to be counted as a loss to the war. The practical consequence was that many kinds of information had to be gotten at the earliest possible date, with greatest difficulty, even though at a later date the same information could be gotten more easily and reliably. The micro-metallurgy of plutonium was investigated at Chicago, for example, because it was vital, among other things, to know the density of the new material as soon as possible; the first measurement was made with great labor, from a sample of only a few micrograms. The value of such information depended upon its capacity to influence decisions which could not be postponed. This meant a heavy dependence upon theory and upon measurements of the type needed to answer theoretical questions. To some extent reliance was placed upon theoretical anticipations because of the all-or-none character of the weapon. A purely experimental nuclear explosion would involve the dissipation of at least one critical mass of material that might have been used against the enemy. If tests were to be made at all, only one or two would be possible. For so small a number of tests to be meaningful, they would have to have a large a priori probability of success. Although this question of tests was not decided at the beginning of the project, certain general implications were clear: The bomb's component parts and phases of operation had to be designed and tested separately, with reliance upon theory to supply a picture of its integral operation.

1.54 It is not remarkable, in the light of what has been said, that the initial program, personnel and equipment of the laboratory gave it the appearance of a purely research organization. That it had this appearance was partly a matter of previous history; nuclear research was the most advanced part of the program, and its personnel and equipment were most easily available. In part, however, the research character of the organization was a matter of

considered policy. Normally, the engineer is the "practical man" who translates ideas into practice. Here, not only the ideas but also the standards of practice were new. To keep the center of policy in the research group was not to minimize the importance of the engineering work, but to emphasize its difficulty. Secondary problems undeniably arose from this policy, which displaced the engineer from his normal position, and only through trial and error created for him a new place in the division of Project labor.

Theoretical Program

1.55 Enough has been said to indicate the central position in the laboratory of its theoretical program. As it emerged from the conferences this program had as its main goal to analyse the explosion, and develop the associated techniques of calculation; to give nuclear specifications for the bomb with increasing reliability and accuracy as new physical data became available. Calculations had to be made for three materials: U^{235}, Pu^{239}, and also a new compound, a hydride of uranium, which seemed to have certain advantages over metallic uranium as a bomb material. Calculations also had to be made for a variety of shapes of the active mass, and for different combinations of bomb and tamper material. For critical-mass calculations the theory of neutron-diffusion in bomb and tamper had to be refined, and account taken of the energy distribution of fission neutrons, as well as the dependence of nuclear cross-sections upon those energies. For efficiency calculation, further study was needed of the hydrodynamics of the explosion, taking account of the effects of the large amounts of radiation liberated in the process. Further investigation was needed of the problems connected with time of assembly, detonation and predetonation.

1.56 In addition to these problems relating to bomb design, the theoretical program included a variety of analyses and calculations connected with the experimental program, ranging from ordinary service calculations to the design of a slow chain-reacting unit with U^{235}-enriched uranium.

1.57 The program included, finally, the further investigation of bomb damage, of the possibility of autocatalytic methods of assembly, and the proposal to amplify the effect of fission bombs by using them to initiate thermonuclear reactions.

Program of Experimental Physics

1.58 The program of experimental physics formulated during and immediately after the conferences falls under two main headings: Detailed and integral experiments. Detailed or differential experiments are those which attempt to observe the effects of isolated nuclear phenomena. From a sufficient number of experimental data gained in this way, an integral picture of the operation of the bomb could be built up within a framework of theory. Integral experiments, on the other hand, were - at least in their early conception - attempts to duplicate in experimental arrangement some of the overall properties of the bomb. Experiments of the two kinds were intended to supplement each other wherever possible; on the one hand to sharpen the interpretation of integral experiments, on the other to show up possible omissions of elements from the detailed picture. In practice, it has proved extremely difficult to devise integral experiments which in any way duplicate the conditions obtaining in the bomb. The integral experiments that have been performed have had rather the effect of checking theory in situations in some ways similar to the bomb.

1.59 A brief outline of the program as first developed will serve also to indicate the state of experimental knowledge carried over from the previous period.

1.60 Differential experiments:

Neutron Number: The average number of neutrons per fission had never been measured directly, although the Chicago Project had measured the number of neutrons from U^{235} per thermal neutron absorbed. The number of neutrons per fission could be calculated from this measurement and from the ratio of fissions to captures, which, however, was not known reliably in the region of

thermal energies. The neutron number of Pu^{239} was completely unknown although it was expected to differ but little from that of U^{235}. The first experiments planned were in fact measurements of neutrons from Pu^{239}.

1.61 These latter measurements were of intrinsic importance, and were needed at the earliest date possible to confirm the wisdom of heavy commitments already made for the production of plutonium in quantity.

1.62 Fission Spectrum: The energy range of neutrons from the fission of U^{235} had been investigated by the British, and by the Rice Institute and Stanford sub-projects. These measurements suffered from the large dilution of isotope 235 by 238 in normal uranium. Work had already been begun at Minnesota with enriched material, and this program was to be continued at Los Alamos.

1.63 Fission Cross Sections: Fission cross-sections had been measured by the sub-project under N. P. Heydenberg at the Department of Terrestrial Magnetism of Carnegie Institute, by McKibben's group at Wisconsin, and by Segre's group in Berkeley. These measurements - for U^{235} - covered the neutron energy range above 125 kev, and the range below two ev. When the curve for fission cross-sections over the high-energy range was extrapolated downward, a figure was obtained for thermal energy that was much larger than the cross-section actually observed. Since the extrapolated region covered the important range of neutron energies in a bomb of uranium hydride, measurements were planned to investigate cross-sections at these intermediate energies, and resolve the apparent anomaly. Fission cross-sections of Pu^{239} were already known at thermal energies and at a few high energies. Here also measurements were planned to cover the entire range of energies up to about 3 Mev.

1.64 Delayed Neutron Emission: Experiments at Cornell had shown that there was no appreciable delay beyond ten microseconds in the emission of neutrons from fission; one of the initial experiments planned at Los Alamos was to push

this time down to a tenth of a microsecond; on theoretical grounds it was expected that the number delayed even for this time would be small.

1.65 Capture and Scattering Cross-Sections: At the beginning of the project little was known about capture and scattering cross-sections. Some measurements of capture and inelastic scattering cross-sections had been made at Chicago for normal uranium. Experiments by the Minnesota group had given values for elastic and inelastic scattering in uranium for high energies. The Wisconsin group had measured large-angle elastic scattering in a number of potential tamper materials. Capture cross-section measurements were made by Segre at Berkeley. The principal work planned for the Los Alamos Laboratory was on the scattering and absorption cross-sections of U^{235} and Pu^{239}, and the capture and scattering cross-sections of various tamper materials.

1.66 One new type of scattering measurement, not previously undertaken, was planned for this laboratory. This was the measurement of scattering into different solid angles. When so averaged as to give the effective scattering in a given direction, this average is the so-called transport cross-section.

1.67 Integral Experiments: Certain integral experiments had been performed at Chicago, in connection with the development of the slow neutron chain-reacting pile. These were not of direct interest to the bomb project. Two types of integral experiments were however planned in the early experimental physics program:

1.68 Integral Tamper Experiments: Several experiments were planned to measure the scattering in potential tamper materials; these were designed to imitate the scattering properties of a tamper in the actual bomb.

1.69 The "Water Boiler": At the April Conferences there was some discussion of the possibility of constructing a slow chain-reacting unit, using uranium with enriched U^{235} content in water solution. The construction of such

a unit would provide a useful neutron source for experimental purposes, and would also give practice in the operation of a super-critical unit. The decision to make such a unit was not reached until some time later.

1.70 Experimental Techniques: A large subsidiary program was called for, to investigate techniques for producing and counting neutrons of a given energy, for measuring fissions in various materials, and for measuring neutron-induced reactions other than fission. The systematic recording of nuclear properties entailed by the experimental program required both accuracy and standardization of a number of difficult techniques; the program of instrumentation represented therefore a major activity of the laboratory.

Program of Chemistry and Metallurgy

1.71 During the course of the DSM Project a large amount of research had been carried out on the chemistry and metallurgy of uranium. The micro-chemistry and micro-metallurgy of plutonium were investigated at Chicago as soon as small amounts of the material were available. The chemical investigations were necessary as a basis for designing methods of recovering plutonium from the pile material and "decontaminating" it, i.e., separating it from radio-active fission products.

1.72 At the beginning of the Los Alamos project the exact division of labor between its chemistry laboratory and other laboratories had not been settled. There were objective difficulties and uncertainties of program. It was not known whether U^{235}, Pu^{239} or both would be used, or whether the bomb material would be metal or compound. U^{233}, producible from thorium by a process of "breeding" similar to that by which Pu^{239} is made from U^{238}, was also a possibility. Mechanical requirements for the bomb material could not yet be specified. Here also a characteristic difficulty appeared, in that the time for research with gram and kilogram amounts of material would have to be as short as possible, in order to avoid delay in bomb production.

1.73 One certainty was a schedule of purity requirements for U^{235} and Pu^{239}. Because of the large alpha radioactivity of the latter substance, light impurities had almost to be eliminated. Most light elements had to be present in not more than a few parts per million. For U^{235} these tolerances could be greatly relaxed. Although it was not yet determined whether the work of final purification would be carried on at Los Alamos or elsewhere, an analytical program was necessary to develop techniques for measuring small amounts of impurity in small samples of material.

1.74 A radio-chemistry program was needed to prepare materials to be used in nuclear experiments and in the development of a neutron initiator for the bomb.

1.75 The metallurgy program included research and development on the metal reduction of uranium and plutonium, the casting and shaping of these metals and compounds such as uranium hydride, as well as various possible tamper materials. Investigation of the physical properties of uranium and plutonium was needed, and a search had to be made for alloys with physical properties superior to those of the unalloyed metals. As its main service function, the metallurgy group would be called upon to prepare materials for physical and ordnance experiments; particularly projectile, target, and tamper materials for the gun program.

1.76 As a somewhat autonomous part of the chemistry program, plans were made for the construction of a deuterium liquefaction plant at Los Alamos. This was to supply liquid deuterium for experimental purposes and for eventual use in the thermonuclear bomb, should its development prove feasible and necessary.

Ordnance Program

1.77 It had been recognized from the beginning that the most difficult of all problems facing the project was to find means for the assembly of several critical masses of material, fast enough to produce a successful high-order

explosion. Subsidiary but still very difficult problems were those of incorporating active material, tamper and assembly mechanism into a practical air-borne bomb. These were the problems of the ordnance division of the project, a division which could haruly be said to exist at the beginning. As a matter of fact, no pre-existing group could have had much success in this work. A new field of engineering was being explored; experience has shown that those successful in this work come from a variety of technical backgrounds, all of which contribute to the field and none of which dominate it: physicists, chemists, electrical and mechanical engineers.

1.78 A corollary feature of the ordnance program has been its simultaneous investigation of alternative methods. The uncertainties of nuclear specification and the possibility that one or another line of investigation might fail, have made such a policy unavoidable. Of the three methods of producing a fission bomb (autocatalysis, the gun, the implosion) that have been discussed, the last two were singled out for early development. Autocatalysis was not eliminated; but it was not subject to development until some scheme was proposed which would give a reasonable efficiency. This did not occur during the course of the project, although autocatalytic methods continued to receive considerable theoretical attention. Of the remaining two methods, the gun appeared the more practical; it used a known method of accelerating large masses to high velocities. The problem of "catching" a projectile in a target and starting a chain reaction in the resulting supercritical mass was obviously a difficult one, but it seemed soluble.

1.79 The method of implosion, on the other hand, was much farther removed from existing practice. The requirement of simultaneous detonation over the surface of a high explosive sphere presented unknown and possibly insoluble difficulties; the behavior of solid matter under the thermodynamical conditions created by an implosion went far beyond current laboratory experience. As even its name implies, the implosion seemed "against nature". Its investigation was

at first undertaken as something to fall back on in case the gun should, contrary to expectation, fail. Credit for the early support and investigation of this method should be given to S. H. Neddermeyer, who at the beginning was almost alone in his belief in the superiority of the method. At a meeting on ordnance problems late in April, Neddermeyer presented the first serious theoretical analysis of the implosion. His arguments showed that the compression of DELETED a solid sphere by detonation of a surrounding high-explosive layer was feasible, and that it would be superior to the gun method both in its higher velocity and shorter path of assembly. Investigation of the method was begun almost immediately. It subsequently received two increases of priority, until at the end of the project it had become the dominant program throughout the laboratory.

DOE b(3)

1.80 During the April conferences, the discussion of ordnance served mainly to outline the problems. Considerable attention had been given to the problem of gun design by R. C. Tolman. One member of the reviewing committee at Los Alamos in April was E. L. Rose, an expert in problems of gun design. Rose showed that by the sacrifice of durability, a quite inessential property, the otherwise prohibitive size and weight of a large gun could be reduced to a point where, together with the target, it could be included in a practical bomb. Other elements of the ordnance program discussed were: internal ballistics of the gun, external and terminal ballistics (guiding and seating of the projectile, initiating of the chain reaction), safety, arming and fuzing devices, release and trajectory of the bomb from a plane.

1.81 It is inappropriate to discuss in detail the experimental program of ordnance at this point. Experimental work did not get under way for several months. On the agenda for immediate action were the prior problems of obtaining test guns and high explosives, of building a proving ground, and of employing or training personnel to carry on the research.

Chapter II

THE BRITISH MISSION

2.1 In December 1943 the first representatives of the British atomic bomb project came to Los Alamos. Their arrival marked the climax of a long series of negotiations between the British, Canadian and American Governments seeking to integrate the scientific work being done in all three countries on atomic bomb research (1.2). These first representatives were O. R. Frisch and E. W. Titterton.

2.2 Although Britain's T. A. Project (The Directorate of Tube Alloys) had had a very high priority in 1942, so many of her physicists and so much of her industrial capacity were engaged in other urgent war work that it was impossible to undertake as large a program as the United States had launched. The British organization decided to limit itself to particular phases of the problem, and established research teams in various university and industrial laboratories.

2.3 In the summer of 1942, sufficient progress toward collaboration had been made so that the British reports on the theory of fission and the fission bomb were accessible to Oppenheimer's group in Berkeley, as well as reports of experimental measurements of nuclear constants. At that time the British analysis of the bomb mechanism was somewhat more advanced than in the United States, so that access to these reports was of substantial value. In November 1942 a memorandum (Appendix 7 , No. 5) was written by Oppenheimer to R. E. Peierls describing the theoretical work that had been done at Berkeley and discussing certain points of difference between British and American theoretical work. The incompleteness of collaboration at this time is indicated by the fact that in the memorandum referred to there could be no mention of the deuterium bomb.

2.4 In the fall of 1943 President Roosevelt and Prime Minister Churchill had discussed the possibilities for closer collaboration between the two countries in hastening the production of Atomic Bombs. As a result of their discussions a Combined Policy Committee was set up in Washington. One of this committee's decisions was to move a large number of British scientists to work in American laboratories. Evidence of the genuineness of cooperation that resulted from this sacrifice on Britain's part is the fact that British scientists were given assignments in all parts of the American Project, especially at Los Alamos, the most highly classified section of all. (Appendix 7, No. 6)

2.5 At this time Niels Bohr, the eminent Danish physicist, escaped from Denmark to England, where he was appointed adviser on scientific matters to the British Government. His scientific advice was made available to the United States as well. Bohr and his son Aage came to Los Alamos in December 1943, a short time after Frisch and Titterton. To ensure his personal safety and as a security precaution, Bohr was known as Nicholas Baker and his son as James Baker. Great care was taken to prevent any reference to their real names, even in classified documents. The Bohrs did not become resident members of the Los Alamos Laboratory, but made several extended visits as consultants.

2.6 When Bohr came to the Laboratory he found there a large number of his former students, and his coming had a very healthy influence on research. He came at the right moment. The exigencies of production, the innumerable small problems which confronted the physicists had led them away from some of the fundamental problems of the bomb. The study of the fission process itself, for example, had been neglected, and this obstructed reliable predictions of important phenomena, such as the energy-dependence of the branching ratio between fission and neutron capture (6.44). Here Bohr's interest gave rise to new theoretical and experimental activities which cleared up many questions that were left unanswered before. Some of the most important experiments on the velocity selector were made at his instigation (6.38). His influence was felt

strongly in research on the nuclear properties of tamper materials.

2.7 Bohr's criticism and his concern for new and better methods enlivened the discussion of alternative means of bomb-assembly. Although these discussions showed in the end that the "orthodox" implosion was still the best method, their value was to prove that its choice was, despite its many difficulties, the correct one. Bohr participated very actively in the design of the initiator.

DELETED DELETED DELETED DOE 6(3)

2.8 Last but not least his influence on the morale of the Laboratory must be mentioned. It went farther than having the great founder of atomic research in the Laboratory, and farther than the stimulus of his fresh suggestions. He saw the administrative troubles of the Laboratory in a better and longer view than many of those enmeshed in them. His influence was to bring about stronger and more consistant cooperation with the army in the pursuit of the common goal. And what can be least overlooked, he gave everybody who was in contact with him some of his understanding of the ultimate significance of the control of atomic energy.

2.9 Another of the Laboratory's most useful British consultants was Sir Geoffrey I. Taylor. Los Alamos was staffed primarily with nuclear physicists, who lacked experience with hydrodynamical investigations. In investigating the hydrodynamics of the implosion and the nuclear explosion, therefore, their work suffered from being too formal and mathematical. Apart from the contributions of the American sonsultant J. von Neumann (7.64), most of the simple intuitive considerations which give true physical understanding came from discussions with Taylor. His most important general contribution was the understanding of the "Taylor instability", which is the generalization that when a light material is pushing a heavy material, the interface between them is unstable (5.27). This principle was important in the theory of jets (16.10), in the interpretation of high-explosive experiments, in the design of the initiator

(15.45), in the design of the implosion bomb, and in the predictions about the nuclear explosion (5.47). To him also was due the stimulus for serious theoretical investigation of the "ball of fire" phenomena (11.28).

2.10 Technical contributions of the resident staff of the British Mission are mentioned in appropriate parts of the text on the same basis as the work of their American colleagues.

2.11 Sir James Chadwick of the Cavendish Laboratory, scientific adviser to the British members of the Combined Policy Committee in Washington, came to Los Alamos early in 1944 to head the British Mission. It was not certain at first whether the British group would work under Chadwick on the problems of his choosing, or whether they would be assigned to existing groups in the laboratory. The latter arrangement was adopted, and eventually British scientists worked in nearly all of the Laboratory Divisions. Seven were experimental nuclear physicists, two were electronics experts, five were theoretical physicists, and five were experts in the properties and effects of explosives.

2.12 Lord Cherwell, Churchill's personal adviser on scientific matters, visited Los Alamos in October 1944.

2.13 Chadwick stayed in Los Alamos only a few months. His successor as head of the Mission was Peierls.

2.14 Apart from the consultants already mentioned, the British Mission staff consisted of the following: E. Bretscher, B. Davison, A. F. French, O. R. Frisch, K. Fuchs, J. Hughes, D. J. Littler, C. Mark*, W. G. Marley,

* Although several members of the Mission came to Los Alamos via the Canadian and United Kingdom Laboratory in Montreal, all were attached to the British staff except C. Mark, who remained in the employ of the Canadian Government.

D. G. Marshall, P. B. Moon, W. F. Moon (secretary), R. E. Peierls, W. J. Penney, G. Placzek, M. J. Poole, J. Rotblat, H. Sheard, T. H. R. Skyrme, E. W. Titterton, J. L. Tuck.

Chapter V

THEORETICAL DIVISION

Organization

5.1 The broad purpose for which the Theoretical Division was formed as had been said (1.55-7) was to develop nuclear and hydro-dynamical criteria relating to the design of the atomic bomb, and to predict the detailed performance of the weapon designed. At the beginning the bulk of the Division's effort, accordingly, was devoted to the investigation of two closely related key problems: the calculation of the critical mass and the nuclear efficiency.

5.2 The first organization of the division centered around these problems. With the rise of the implosion to prominence the organization of the Division, under H. A. Bethe as Division Leader, was formalized as follows (beginning March 1944):

T-1.	Hydrodynamics of Implosion, Super	E. Teller
T-2.	Diffusion Theory, IBM Calculations, Experiments	R. Serber
T-3.	Experiments, Efficiency Calculations, Radiation Hydrodynamics	V.F. Weisskopf
T-4.	Diffusion problems	R.P. Feynman
T-5.	Computations	D.A. Flanders

5.3 During June, 1944, R. Peierls took charge of the Implosion Group in place of E. Teller who formed an independent group outside the Theoretical Division (13.1). This group acquired full responsibility for implosion IBM Calculations. During July 1944 Group O-5 (F-8) joined the Theoretical Division on a part time basis, its work in the Ordnance Division being largely completed (14.1).

Diffusion problems.

5.4 One of the tasks of the theoretical program at the beginning of the Laboratory was the development of means for predicting accurately the

were of three velocities (fission energies, intermediate and thermal). A number of other methods mentioned above were also tried out on this problem, primarily with the purpose of examining the variation among them and as a test of their power when applied to a new problem. The finally predicted value of the critical mass for the water boiler was almost exactly correct; a pleasing, though rather fortuitous result in view of subsequent revisions of the cross-sections involved.

5.16 A number of other problems affecting the operation of the water boiler were examined theoretically; cooling and shielding, effects of temperature changes on the degree of criticality, effect of sudden changes in the position of the control rods, etc. After the boiler was put in operation, the theorists were of service in connection with experiments, such as the interpretation of fluctuations in its operation. This work was essentially completed by the beginning of 1944. Most groups participated in one or another type of water boiler calculation, but the main work was that of R. F. Christy in Group T-1.

DOE b(3)

The gun.

5.17 Critical mass calculations for the gun assembly were complicated primarily by the odd shape of the assembly. DELETED DELETED DELETED The critical mass problem for the gun was not only that of estimating the number of critical masses in the completed assembly, but also of estimating the amount of active material that could safely be disposed in the two parts before assembly. It was also necessary to know how the system went from its initial subcritical to its final supercritical position, in order to be able to calculate the probability of predetonation. The early rough specifications for the gun had been based on critical mass estimates from

differential diffusion theory.

DOE b(3) 1

DELETED DELETED DELETED

By February 1944, there was pressure from the Ordnance Division to obtain more reliable specifications, and at this time sufficiently accurate calculations had been made so that, for the U^{235} gun, Group T-2 specified a DELETED gun. The specification of the DELETED for the Pu^{239} assembly was reached a short time later. The same group was able to give essentially complete specifications by the summer of 1944 for both gun assemblies, fortunately after cross-section measurements by the Detector Group had resulted in slightly lower average values for U^{235} than those used in earlier calculations.

DOE b(3)

DOE b(3)

The Implosion

5.18 The history of theoretical implosion studies lies mostly outside the Theoretical Division until the Fall of 1943. The idea of something like an implosion, as an alternative to gun assembly, had entered several heads before the beginning of Los Alamos. Its first history at Los Alamos belongs mainly to the Ordnance Division, where the initial calculations of attainable assembly velocities were made.

5.19 The Theoretical Division entered the picture when the fast implosion was proposed by von Neumann, and its potentialities as a weapon qualitatively superior to the gun were appreciated. The general story of this development is told in Chapters 7, 15 and 16. Here the emphasis will be upon the theoretical problems that were involved. Implosion studies were the responsibility of Group T-1, with the assistance of other groups, particularly T-2.

5.20 The first problem attacked was that of the time of assembly when (as proposed by von Neumann) large amounts of explosive were used. In this case, the energy required for the work of plastic deformation was small compared

DOE b(3)

to the total energy of the explosive, so that to a first approximation the kinetic energy of the mass moving inward could be assumed to be conserved.

DELETED

DELETED

DELETED

DELETED

The numerical solution of the partial differential equation describing the implosion was too difficult for hand calculation with the computing staff available at Los Alamos, when a realistic equation of state was employed. As a result the first effort made was to find simpler approximate equations of state. The first method was based on a multiphase model, in which the state of the imploding material was assumed to change discontinuously. A considerable amount of effort was put into the multiphase model, but the results proved very difficult to interpret.

DOE b(3)

5.23

DOE b(3)

These machines arrived in the first part of April, 1944, and in the meantime preparations had been under way for numerical integration of the hydrodynamical equation by means of them. Preliminary calculations had to be made to determine the initial conditions at which to start the IBM calculations. It was necessary to derive the equation of state of uranium at high pressures, a calculation based on the Thomas-Fermi model of the atom. Results at low pressures were obtained from experimental data of P. W. Bridgman, and the intermediate region determined by interpolation.

5.24 The first results of IBM calculation of the implosion were extremely satisfactory. As a result the unrealistic multiphase implosion model was dropped.

DOE b(3)

Efficiency.

5.32 The calculation of efficiency was perhaps the most complex problem that the Theoretical Division had to face. The theory of efficiency had to follow the neutron chain-reaction and neutron distribution in the bomb, in a medium of fissionable and tamper material that was itself being rapidly transformed by the reaction in both its nuclear and dynamic properties. Every factor involved in the critical mass calculations was involved here, but in a dynamical context which made dubious some of the simplifying assumptions underlying those calculations.

Calculations were so insecure that they were never incorporated into the final efficiency calculations for the bombs produced in 1945. But an understanding of the theory in qualitative terms was an important factor in the final decisions on tamper specifications.

The Super.

5.50 The deuterium bomb or "Super" project was relatively divorced from the main work of the Laboratory. As a development secondary to that of the fission bomb, its importance was nevertheless such that it was carried on throughout the course of the Laboratory. From its first conception, before

Los Alamos, this work was under the direction of Teller. In the last period of the Laboratory Teller was joined by Fermi. By coincidence the first idea of such a bomb, at least in relation to the Los Alamos program, had been evolved in a lunchtime discussion between Fermi and Teller early in 1942.

5.51 A fundamental understanding of the fast thermonuclear reaction had been reached by the beginning of Los Alamos. In the first rough calculations Teller had ignored the effect of radiation, which is to drain off energy at a rate that increases rapidly with temperature. These early rough calculations indicated that the reaction would take place if ignited by the explosion of a fission bomb as "detonator". They also indicated, in fact, that the reaction would go too well, and that the light elements in the Earth's crust would be ignited.

DOE (b)(3)

DELETED

DELETED

DELETED

DELETED

DOE b(3)

DELETED DELETED DELETED

5.54 These matters were well enough understood in the Summer of 1942 to make it apparent that a Super could, in principle, be made. At the Berkeley summer conference in 1942, Teller presented his analysis of the mechanism and argued that such a bomb was feasible. A good part of the discussion at this conference was devoted to the examination of Teller's proposals.

DOE b(3)

DELETED DELETED DELETED DELETED

5.56 One further suggestion of great eventual importance was made by Konopinski. This was to lower the ignition temperature of deuterium by the admixture of artificially produced tritium (hydrogen ^{3}). The apparently very much greater reactivity of tritium led him to this proposal. It was not immediately followed up because of the obvious difficulty of manufacturing tritium and the hopefulness of igniting pure deuterium. Eventually, as it will

develop, new difficulties of ignition were to be uncovered so that the introduction of artificial tritium began to appear necessary.

5.57 One further topic was discussed at the Berkeley conference, the effect of secondary nuclear reactions. Products of the deuterium-deuterium (D-D) reaction were, with about equal probabilities, a helium^3 nucleus plus a neutron, or a tritium nucleus and a proton. It was pointed out by Bethe that the reaction of deuterium with tritium, even though secondary, was of considerable importance. The T-D reaction releases nearly five times as much energy as the D-D reaction; the reaction cross-section was moreover likely to be considerably larger.

5.58 The consequences of the Berkeley discussions of the Super were that its investigation was continued, that measurements of the D-D and T-D cross-sections were undertaken, and that, when the Los Alamos Laboratory was being planned, a research program on the Super was included.

5.59 After the conference and before Los Alamos the measurement of the D-D cross-section was undertaken by Manley's group at Chicago, and that of the T-D cross-section was undertaken by Holloway's group at Purdue.

5.60 At Los Alamos no systematic theoretical work on the Super was undertaken until the fall of 1943. A cryogenic Laboratory was started by the group under E. A. Long, with the object of building a deuterium liquefaction plant. A considerable amount of work on the properties of liquid deuterium was carried out by Prof. H. L. Johnston under subcontract at Ohio State University (8.96 - 8.99).

5.61 In September, Teller proposed that there be more intensive investigation of the Super. Experimental cross-sections had been revised upward, so that the bomb would be feasible at lower temperatures. In addition there was some slight evidence that the known German interest in deuterium might

be directed toward production of a similar bomb. Work was resumed at this time, but not with high intensity. Teller and his group were largely occupied with other and more urgent problems.

5.62 In the Winter of 1943-44 an important new theoretical problem was uncovered.

DOE b(3)

DELETED DELETED

DELETED DELETED

5.63 The recognition of this new dissipative mechanism became the occasion for a revaluation of the Super program. This program was discussed at length in a meeting of the Governing Board on February 24, 1944, at which Teller reported on the current state of knowledge (Appendix 7, No. 20). Detailed quantitative investigation of DELETED DELETED was needed, but would lengthen the time-scale of the program. In case these

DOE b(3)

investigations should show that the difficulty of igniting deuterium was too great, there was one remaining alternative, which was to return to the proposal of Konopinski to lower the ignition temperature by admixture of tritium. A small percentage of tritium would bring the ignition temperature down from the neighborhood of twenty kilovolts to around five. DELETED

DOE b3 DELETED DELETED

5.64 The practicability of using a tritium-deuterium DELETED DOE b(3) limited by the very great difficulty of obtaining tritium. It could be produced from the reaction of neutrons with lithium^{6}, yielding tritium and helium^{4}. The very small sample of tritium that had been used in cross-section measurements at Purdue had been produced by cyclotron bombardment. Larger scale production would be possible in such a pile as the Hanford pile, but could utilize only the small percentage of excess neutrons not needed to keep the pile in production.

5.65 Both because of the theoretical problems still to be solved and because of the possibility that the Super would have to be made with tritium, it appeared that the development would require much longer than originally anticipated. Even though this was the case, it was decided that work on the feasibility of so portentous a weapon should be continued in every way possible that did not interfere with the main program. Tolman, who was present at this meeting as General Groves's adviser, affirmed that although the Super might not be needed as a weapon for the war, the Laboratory had a long-range obligation to carry on this investigation.

5.66 Although no final decision was made at the meeting referred to, it in fact defined subsequent policy. In Teller's group further theoretical work was carried on, which confirmed the difficulty of igniting pure deuterium.

In May 1944 Dr. Oppenheimer discussed the matter of tritium production with General Groves and C. H. Greenewalt of the du Pont Company. It was there decided that experimental tritium production would be undertaken, using surplus neutrons in the Clinton pile.

Damage.

5.67 The detailed investigation of damage and other effects of nuclear explosion was not pursued very far in the period under review. Some results, going beyond the rough estimates reported in 1.52 were, however, obtained in the summer and fall of 1943. There was further investigation of the shock wave in air produced by the explosion, of the optimum height for the explosion, of the effects of diffraction by obstacles such as buildings and of refraction caused by temperature variation. There was some calculation of the energy that might be lost through the evaporation of fog particles in the air. Estimates were made of the size of the "ball of fire" after the explosion, and the time of its ascent into the stratosphere. The theory of shallow and deep underwater explosions was investigated, and led to the suggestion of model experiments.

5.68 One important question was cleared up at this time, which was the nature of the dependence of damage upon the characteristics of a shock wave in air. For small explosions damage is roughly proportional to the impulse, which is pressure integrated over the duration of the pulse (i.e., the average pressure of the pulse times its duration). Investigation made clear the fact (not unknown elsewhere) that existing blockbusters are near the limit of size at which further increase of the duration of the pulse has any advantageous effect on the damage. For large explosions such as those contemplated, damage depended only on the peak pressure. This was important because the peak pressure depended on the cube root of the energy, whereas the impulse depended on its

two-thirds power. Large bombs are relatively less effective (from the point of view of purely physical damage) than small ones for this reason. Calculations made at the time showed that for bombs of the order of ten thousand tons of TNT, the peak pressure would fall below the level of "C" damage at a radius of 3.5 kilometers.

5.69 Another important point was clarified at this time, connected with the optimum height of detonation. It had been known that the reflection of shock-waves by solid obstacles increases the pressure of the shock wave. It was shown at this time, however, that this effect was much greater for oblique incidence than had been believed from elementary considerations; in fact oblique incidence up to an angle of sixty or seventy degrees from the vertical gives a greater pressure increase than normal incidence. Hence it was concluded that a considerable improvement in the damage radius could be obtained by detonation at an altitude not small compared to the expected radius of damage--in fact of one or two kilometers.

Experiments

5.70 Some of the more important cooperative work as between the Theoretical Division and the other divisions of the Laboratory has already been mentioned; for example the interpretations of scattering data, and calculations of the water boiler and hydride critical masses, and the calculations made of the hydrodynamical characteristics of the implosion. There was however a more extensive cooperation than these isolated instances would suggest. Work done ranged from cases such as these in which the theorists played a large and semi-independent role, to ordinary service calculations, particularly the analysis of experimental data. For this latter work and for consultation in the design of experiments, every experimental group had theorists assigned to it. Calculations of a fairly extensive sort were necessary in all experiments in

which "integral" considerations were involved, i.e. in which the results depended upon nuclear constants in a complex statistical way. For it then became necessary to relate the measured quantities with these constants by theory, and to use this theory first to decide whether a given experimental design would yield sufficient accuracy to justify its execution, and second to interpret the data obtained. The theorists played this part in most of the experimental determinations of nuclear quantities described in Chapters VI and XII.

5.71 One rather conspicuous example of theoretical influence on the design of experiments was the "Feynman experiment", an experiment which was never performed but whose principle was embodied in several experiments. This was simply the proposal to assemble near-critical or even supercritical amounts of material safely by putting a strong neutron absorber (the B^{10} boron isotope) uniformly into the core and tamper. For an absorber with an absorption cross section inversely proportional to the velocity of the neutrons absorbed, it could be shown that the effect was to decrease the multiplication rate in the system by an amount which was directly proportional to the concentration of absorber. Thus an amount of material which would be supercritical could be made subcritical by the addition of boron; from a measurement of the rate at which the neutron <u>died out</u> in this system, the rate could be simply calculated at which they would <u>increase</u> if the boron were absent.

5.72 The theoretical groups assisted the Detector Group of the Experimental Physics Division and others in the theoretical analysis of the efficiency and other characteristics of detectors and counters.

5.73 Aside from its main work in connection with the gun and implosion assemblies, discussed above, the Theoretical Division made numerous

other analyses and calculations relative to the experimental work of the Ordnance Division. In preparation for the RaLa experiments for example, Group T-3 analyzed the attenuation of gamma-rays in a homogeneous metal sphere surrounding the source, and calculated the way in which this attenuation would be increased with compression during the course of an implosion of the metal sphere. As another example, the theory of the magnetic method of implosion study was investigated in the Theoretical Division in collaboration with the experimentalists.

5.74 Mention should be made here of safety calculations made by Group T-1 and later by Group F-1 for the Y-12 and K-25 plants. The Group Leader, E. Teller, was appointed as consultant for the Manhattan District as a whole on the dangers of possible supercritical amounts of material being collected together in the plants producing separated U^{235}.

5.75 During the period described the computations group, T-5, carried out innumerable calculations for other groups in the Division, and related investigations in the mathematical theory of computation. Like other service groups, its scanty mention is no indication of the importance of its work, without which the work of the division would have been in fact impossible.

design, the choice of a tamper had to be made as soon as possible. The notion prevailed for some time that inelastic scattering (i.e., scattering, in which the neutrons, although not captured by the tamper nuclei, lose part of their energy to them by excitation) would play an unimportant role, since it would probably reduce neutrons to a very low energy where they would not contribute materially to the explosive chain reaction. Very little was known, moreover, about the variation of scattering with neutron energy. It was thought, at the time, that the most important part of the fission spectrum lay at high energies, near 2 Mev. It was felt that to a first approximation the usefulness of a tamper would be determined by the number of neutrons reflected backward to the core. It was therefore decided that the most rapid collection of pertinent information could be made by comparing the back scattering of trial tamper materials for D(d,n) neutrons from the Cockcroft-Walton. This could be done using either a non-directional detector with a paraffin "shadow cone" to reduce direct beam, or with a directional detector. The shadow cone method greatly reduced the range of scattering angle measurable. It was thought that a directional detector could give an average over the angles from 120° to 180° in the geometry possible.

6.50 The D-D Group undertook these measurements by both methods in August 1943. The first directional detector was a spherical ionization chamber with a large directionality factor. The first scatterers measured were discs 1 inch thick and 10 inches in diameter of lead, iron, gold and platinum. The latter two, vulgar wonders in an atomic bomb laboratory, brought a great stream of visitors from other groups. Lead showed up best per unit weight, but because of its relatively low density was not much better than gold or platinum.

6.51 Although the geometry used for back-scattering covered the angles 120° to 180°, it was discovered - as theory caught up with experiment - that a very small range of angle near 137° was weighted predominantly. Hence if back scattering were not uniform, the data obtained could be quite misleading. Several councils

of war about this state of affairs resulted in an extension of the measurements.

6.52 This incident was of some importance in the growth of the Laboratory. An essential part of the design of such an experiment as this is sufficient preliminary analysis and calculation to show that from a given experimental arrangement the data sought can actually be got. For efficiency most of the elaborate calculations of this sort are delegated to members of the Theoretical Division because of their special skill. In this case the liaison between the latter and the D-D Group had been inadequate and a need for closer liaison was recognized.

6.53 By the end of October 1943 back-scattering measurements had been completed for a large list of substances, and a number of instrumental improvements had been made. After the first survey, the list of possible tamper materials was restricted to tungsten, carbon, uranium, beryllium oxide, and lead. At about this time, also, measurements of the fission spectrum indicated that the important energy range was nearer 1 Mev than 2 Mev. Results of the first experiments indicated, moreover, that earlier ideas about inelastic scattering were incorrect, and that inelastically scattered neutrons could play an appreciable role in the functioning of a tamper. Recognition of their possible importance was made easier, also, by the current concern of the Laboratory with the uranium hydride bomb. The same increase in cross section with decreasing energy that made this bomb seem feasible also suggested that neutrons slowed by inelastic scattering might still make a considerable contribution to an explosive chain reaction.

6.54 For these reasons preparations were made for the study of scattering as a function of energy and scattering angle, taking account of inelastically scattered neutrons. This work was done cooperatively by the D-D and Electrostatic Generator Groups, beginning in November 1943. Back-scattering data were obtained at 1.5 Mev and 0.6 Mev, as well as 3 Mev. In addition to

overall back-scattering measurements, an experiment was performed to give specific information on the degraded neutrons as a function of primary neutron energy for the elements still in the running as scatterers.

6.55 Materials studied in these experiments were carbon, lead, uranium, beryllium oxide and tungsten. These are listed in the order in which they appeared promising. DELETED DELETED DELETED During May, June and July 1944, this series of experiments had been extended to uranium nitride, lead dioxide, cobalt, manganese, nickel and tantalum at several energies. DELETED DELETED DELETED

6.56 One further scattering experiment was begun in this period, an integral experiment which would attempt to obtain information about the hydride bomb. The D-D source was to be surrounded by a modifying sphere mocking the hydride core as nearly as possible, integral tamper properties would be investigated around this core as well as neutron distribution in tamper and core. One instrumental development that occurred in this connection was a new fission detector. This was a spiral ionization chamber with a spiral of depleted U^{238} so wound as to give a large surface area in a small volume. This counter operated at efficiencies as high as 85 per cent.

The Water Boiler

6.57 The first chain reacting unit built at Los Alamos was the water boiler, a low-power pile fueled by uranium enriched in U^{235}. It was the first pile built with enriched material, the so-called alpha stage material containing about 14 per cent U^{235}. The necessary slowing down or moderation of fission neutrons is provided in this system by the hydrogen in ordinary water: the active mixture is a solution of uranyl sulfate in water solution. The tamper chosen was beryllium oxide.

DOE b(3)

The necessary presence of Pu^{240} in the Hanford plutonium (4.52) decreased the minimum time of assembly of this material far below what was possible by gun-assembly methods.

DOE b(3)

DELETED DELETED DELETED

Projectile, Target and Initiator Design

7.31 Although the development of designs of projectiles, targets and initiators for the gun assembly should be capable of moving more rapidly than the development of the gun itself, the uncertainties surrounding the problem were relatively more serious. Not only were the physical properties of plutonium entirely unknown, but the whole problem of producing an assembly of projectile and target that would start the chain reaction under favorable conditions, i.e. at the right time and in a compact geometry, was entirely new. Accumulated experience on armor penetration greatly discouraged early suggestions that the projectile be stopped by the target. The conception of a gun assembly, as of April 1943, was rather one in which the projectile passed through the target freely

DOE b(3)

DELETED DELETED DELETED

7.32 Before any work was started on these developments, the plan was complicated by the further uncertainty in the amount of active material that could be safely disposed in the projectile alone, or in the target. This was particularly important in the case of the hypothetical uranium hydride gun; for here the critical mass would be small, while for effectiveness a large number of critical masses would

have to be assembled. [redacted]

DOE b(3) [redacted] Although planned primarily for the hydride gun, the critical mass calculations for odd metal shapes were not at the time accurate enough to rule out a possible need for such methods in the metal gun model. The development of these mechanisms was a difficult undertaking which remained uppermost in the efforts of the groups concerned until February 1944, by which time the hydride gun had been abandoned [redacted]

7.33 The design development of projectiles, targets [redacted] was centered in the Projectile and Target Group. [redacted]

DOE b(3)

DELETED DELETED

DELETED DELETED

7.64 Interest in the implosion thus remained secondary to that in the gun assembly. There was some consideration of the possibility of using larger amounts of explosive to increase the velocity. But the impossibility of recovery and the currently incomplete instrumentation kept such things in the "idea" stage for several months. The decisive change in this picture of the implosion occurred with the visit of J. von Neumann in the fall of 1943. Von Neumann had had previous experience with the use of shaped charges for armor pentration. Von Neumann and Parsons first advocated a shaped charge assembly, by which active material in the slug following the jet would be converted from a hollow cone shape to a spherical shape having a lower critical mass value. He was soon persuaded, however, that focussing effects similar to those which are responsible for the high velocity of Monroe jets would operate within an imploding DELETED sphere. DELETED

DOE b(3)

DELETED DELETED DELETED

DOE b(3)

DELETED DELETED DELETED

7.65 It cannot be said that these radical proposals were unanticipated in the Laboratory. Certainly their qualitative peculiarities had not been grasped, or urged as a decisive advantage. Predominantly until this time the implosion had been conceived as a means of squeezing solid matter into a solid sphere, with quantitative advantages over the gun, to be weighed against its much greater uncertainty of success.

DOE b(3)

DELETED DELETED DELETED

7.66 Once discussion was started on this plane, a further fact of great ultimate importance became apparent. In conversations between von Neumann and Teller the latter pointed out that

DOE b(3)

DELETED DELETED DELETED

DOE
b3

DELETED

DELETED

DELETED

DELETED

7.68 Another major consequence of the new emphasis was the planning and eventual realization of an adequate high explosives production plant and research program. For this development as well as for general assistance to the research in implosion dynamics, the consulting services of G. B. Kistiakowsky were acquired by the Laboratory in the fall of 1943. In February 1944, Kistiakowsky joined the staff as Capt. Parsons' deputy for the implosion. In April he assumed full direction of the rapidly increasing administrative problems of this work.

7.69 The period preceding February 1944 was spent in vigorous development of experimental techniques. The art of recovery from weak charges was the most rapidly exploited technique, since it required no elaborate instrumentation. Procurement of the spheres required was beyond the capacity of the laboratory shops; outside procurement was arranged through the offices at Detroit and Los Angeles. Although the test conditions were admittedly far from those in a fast

implosion, the recovery technique proved useful in the interpretation of the process and in revealing the importance of and possible difficulties in obtaining symmetry. By February evidence had been obtained of possible trouble from the interaction of detonation waves and from the spread of detonation times in multipoint detonation. These were not yet, to be sure, thought of as basic defects lying outside the range of existing experimental techniques to correct.

7.70 The other techniques that were inaugurated in this period were chiefly in a stage of being perfected to the point where they would be of quantitative usefulness to the investigation. The difficulties lay principally in the necessity for recording events inside an explosive and for timing these events within an uncertainty of the order of one microsecond. In November a program for photographing the interior of imploding cylinders by high explosive flash light, (a method developed at Bruceton) was started. Some qualitative results were soon obtained but refinement of the method and elimination of secondary blast effects required until spring to achieve. Practically the same history applies to the flash X-ray method of studying small spheres. The principal problem presented by this method was the precision of time correlation between the implosion and the X-ray discharge. This problem was solved, in cooperation with the Ordnance Instrumentation Group, by extensive modification of the commercial X-ray machines. The Instrumentation Group had also designed and had constructed rotating prism cameras making use of ultra-centrifuge techniques. These were adapted to proving ground use for taking rapidly repeated photographs of cylindrical implosions in December and January, but were never used effectively for their intended purpose. Much later they were used successfully in lens investigations (16.46). Also in December, field preparations were started for taking electronic records of objects imploded in a magnetic field. The first shot of this type, the "magnetic method", was fired January 4, 1944, and the results were encouraging. The "magnetic method" was designed to take advantage of the fact that the motion

of metal in a magnetic field alters the field. Thus the inward motion of an imploding metal [redacted] would induce a current in a surrounding coil, and the proper interpretation of this current would give information on the velocity and other characteristics of the implosion. Considerable perfection of the electronic records was needed, however, and this held up final proof of the method until spring.

DOE b(3)

7.71 Quantitative data from the X-ray, high explosive flash and rotating prism camera techniques showed the usefulness of these methods for determining velocities and symmetry at small scale, but also indicated a necessity for controlled quality of high explosive castings and boostering systems, as well as improved simultaneity of detonation. Programs were instituted for the improvement of these services; this involved the production of castings of uniform density and composition by the institution of quality control, including X-ray examination and density measurement of charges. In view of the impending large scale production of heavy charges, development work was also undertaken on methods of casting and examining such charges for controlled quality.

7.72 Whereas the original Anchor Ranch Range had been designed to accommodate both the gun and implosion programs, the expansion of the latter soon crowded the Anchor facilities. In particular the casting and detonation of large charges required a large casting plant and several widely separated test sites. The largest of these units, the casting plant, was begun in the winter of 1943. It included an office building, steam plant, a casting house, facilities for trimming and shaping high explosive castings and magazines for storage of high explosive and finished castings.

7.73 This S site (sawmill site) was one of the most difficult undertakings of the Laboratory from an administrative point of view. To find men with experience in high explosive casting work, or even with general experience in handling explosives, proved for the most part impossible. Supervisory personnel were equally difficult to obtain. Almost the only available channel was the army;

the 3 Site Group was staffed almost entirely by men in the SED. Among these a few had appropriate industrial backgrounds, a larger number were young soldiers with some scientific training, usually in chemistry, and the rest were relatively unskilled hands. Originally scheduled for completion in February and full operation in April 1944, steady operation on a reasonable scale did not actually get under way until August. Because of increasing demand and the unavoidable lag in 3 site expansion, it was early in 1945 before the small original Anchor casting room was fully replaced as a source of supply for experimental charges.

7.74 The first of the new experimental methods to be successfully adapted to work at larger scale was the high explosive flash technique, which was used not only with cylinders but also with hemispheres. In the early months of 1944 attention was being given to extending flash X-ray methods to larger scale and using a grid of small ion chambers instead of photographic recording. This work was, however, only begun in the fall (15.19ff). The "RaLa" method, that of including a strong source of gamma radiation in the imploding sphere and measuring the transmitted intensity as a function of time, was being discussed, and active development was gotten underway, including electronic instrumentation and preparation for handling the highly radioactive radio-lanthanum (RaLa) to be used.

DOE (3) b

DELETED DELETED DELETED

The possible use of the betatron to produce penetrating radiation for work with large spheres was discussed at this time; but it was not decided to use the technique until the beginning of the second period (15.26 ff). Lastly, the possibility of making a full-scale, active test in a closed vessel was also being considered and model tests were started and procurement possibilities investigated. Use of such a containing vessel would permit recovery of active material in case of a

complete fizzle. This later grew into the "Jumbo" program which, together with other engineering problems, was centralized under the Ordnance Instrumentation Group and later under a special group devoted to this program (16.53 ff).

7.75 Preparations for an implosion test with active material were begun in March 1944. The main problems were (a) the choice of a test site, (b) the investigation of methods to permit recovery of active material in case of failure of the nuclear explosion, and (c) the design of instrumentation to measure blast effects and nuclear effects of a successful explosion. Discussion of the third topic is referred to Chapter XVIII. Sites considered were in New Mexico, Colorado, Arizona, Utah and California, as well as several island sites off the coasts of California and Texas. In making the choice the advantage of nearness to Los Alamos had to be weighed against possible biological effects even in sparsely populated areas of the Southwest. During the period before August 1944 a good deal of exploration was by map, automobile and plane, and still more was planned. Investigation was begun, finally, of several aspects of the recovery problem. Recovery from a large containing vessel strong enough to withstand the shock of the high explosive alone was the principal means considered. Also investigated was the possibility of setting off the bomb inside a large sand pile which would prevent dispersal and permit recovery of active material in case of failure. Other methods were investigated, but during the period in question the main problem was that of designing "Jumbo", the containing vessel.

7.76 The main activities of the spring and early summer months may be summarized as follows: (1) the preliminary development of new methods, such as RaLa, the magnetic method, the counter X-ray method, which should be useful with larger scale implosions; (2) increasing production and quality control of cast explosives and detonation trains; (3) increased investigation of questions of simultaneity in detonation, including the preliminary investigation of electrical detonation systems; and (4) the exploitation of techniques established during the

winter for studying the implosion. Implosion studies only reached the stage of giving regular and reliable results during the summer of 1944: being concerned with end results, they were the object of great attention from the rest of the Laboratory and particularly from the Theoretical Division. In fact this early work laid the foundation of a new branch of dynamics, the physics of implosion. It had been firmly established that the earlier results on implosion velocities were essentially correct, and considerably lower than theory predicted for normal impact by a detonation wave. The dynamics of confluent materials had also been thoroughly investigated.

DOE b(3)

DOE b(3)

7.77 In July 1944 DELETED DELETED

DOE b(3)

DELETED e Laboratory faced the fact that the gun method could not be used for the assembly of plutonium. Hence at that time there was not a single experimental

result that gave good reason to believe that a plutonium bomb could be made at all. There was, however, a large investment in plants and proving grounds and a wide background of experience in improving explosives and timing, which made it possible to launch an even more ambitious investigation of the implosion. The new development was to be centered on the possible use of explosive "lenses" which could be designed to convert a multiple point detonation into a converging spherical detonation wave and thus eliminate the troublesome interaction lines. Preliminary studies of such systems had been made in England and at Bruceton and the work of adapting them to the implosion problem became the principal objective of the implosion groups. The requirement for experimental lens-mold design was the most difficult initial step and this occupied some months. Meanwhile, the effort to eliminate the interaction jets from non-lens implosion continued

DELETED DELETED

DELETED DELETED

7.79 The decision to go into the study and use of explosive lenses entailed expansion of research DELETED DELETED DELETED Furthermore, the eventual production of these special explosive systems had to be provided for. To be prepared for the use of the first quantities of plutonium all this had to be accomplished well within a year. The major portion of the Laboratory was accordingly reorganized so as to concentrate its manpower

and facilities on the implosion problem. Division X was formed, under Kistiakowsky, for the purpose of experimentation with explosive systems and their method of fabrication and for setting up an adequate production system for all special charges (9.1 ff, Ch. XVI). Also under Division X were put the more or less established methods of implosion investigation, such as the small scale X-ray and the high explosive flash methods. The development of new or as yet unproved techniques for the investigation of implosion dynamics, and the responsibility for design development of the active core of the implosion was made the objective of G Division under Bacher (9.1 ff, Ch XV). The urgency of the directives of these divisions is readily appreciated when it is considered that there was no approved design of either explosive or mechanical systems at the time of the reorganization, August 14, 1944.

Delivery

7.80 The work of the Delivery Group covered everything from the completed bomb (gun or implosion model) to its final use as a practical air-borne military weapon. In the nature of the case there was considerable overlapping between its responsibilities and those of the groups engaged in final bomb-design; particularly with the Fuse Development Group (7.42 ff), the Engineering Group (7.49 ff) and other groups responsible for bomb design. Even in these cases however, it was the especial responsibility of the Delivery Group to see that cooperating groups functioned smoothly together as a team with an eye to their eventual collaboration in combat delivery. In addition to this responsibility and to its own proper functions in design and procurement, the Delivery Group was responsible for liaison with Air Forces activities including the choice and modification of aircraft and the supervision of field tests with dummy bombs. In the second part of this history it will be seen that the activities of the Delivery Group (then expanded into what was called Project A) were extended to include the planning and establishment of the advance base where the bombs were assembled, [illegible] of the bombs, and the tactical training of

the bombs in flight (Chapter XIX).

7.81 The first activities of the delivery program began in June 1943 when N. F. Ramsey (then still working with the Air Forces) undertook to investigate available planes with respect to their bomb carrying capacity. DOE b(3) DELETED DELETED DELETED The only plane which would fit this requirement was the B-29, which even so could carry the bomb only by joining the bomb bays. The possibility of wing-carriage by other planes had been considered and rejected. At this time it appeared that there might be considerable difficulty in obtaining a test B-29. Another plane capable of carrying the bomb was the British Lancaster, and some investigation was made of the possibility of using this plane. In terms of standardization of maintenance, however, this plane would have been difficult to operate from American bases; it was therefore decided that the B-29 would have to be used.

7.82 Preliminary ballistic tests were made in August 1943 at the Naval Proving Ground at Dahlgren, ostensibly for the Air Corps. DOE b(3) DELETED DELETED DELETED These models consisted of a long 14" pipe welded into the middle of a split standard 500 pound bomb. They showed, on testing, extremely bad flight characteristics. In subsequent months further tests of scale models were made at Dahlgren, and models developed which had much better flight characteristics. During this period preliminary models of a proximity fuse developed at the University of Michigan (7.45) were also tested.

DOE b(3)

7.83 On the occasion of Ramsey's first visit to Los Alamos in September 1943, the [redacted] implosion (7.64) was just being urged by von Neumann. From this model a preliminary estimate was made of a nine thousand pound bomb with a diameter of 59 inches. On the basis of these estimates the Bureau of Standards bomb group was asked, through the Bureau of Ordnance, to have wind-tunnel tests

made to determine the proper fairing and stabilizing fins for such a bomb.

7.84 In the Fall of 1943 plans for full scale tests were gotten under way. For the purpose of B-29 modification, two external shapes and weights were selected as representative of current plans at Los Alamos. These were respectively 204 and 111 inches long, and 23 and 59 inches in diameter, the "Thin Man" (gun) and "Fat Man" (implosion). In November 1943 Ramsey and General Groves met with Colonel R. C. Wilson of the Army Air Forces, and plans were discussed for the first modified B-29. In December the first full scale models were ordered through the Detroit Office, and Ramsey and Capt. Parsons visited the Muroc Airbase to make the necessary test station plans.

7.85 Tests were begun at Muroc early in March 1944. The purpose of these tests was to determine the suitability of the fusing equipment, the stability and ballistic characteristics of the bombs, and the functioning of the aircraft and bomb release mechanism. The flight characteristics of the Thin Man model proved stable, while those of the Fat Man were under damped which caused a violent yaw and rotation. The fuses tested, the Michigan proximity fuses (7.45), failed almost completely. The release mechanism proved inadequate for the Thin Man. Four models "hung up" with delays of several seconds. The last model tested released itself prematurely, while the plane was still climbing for altitude. This bomb dropped on to the bomb bay doors, which had to be opened to release the bomb and were seriously damaged. This accident ended the tests pending repair of the plane and revision of the bomb release mechanism.

7.86 Tests at Muroc were not resumed until June, pending plane repair and modification. The intervening time at Los Alamos was devoted to a number of activities: the analysis of the first Muroc data, the planning of a functional mock-up of the plane and bomb-suspension for handling, loading, shaking and cold tests, and construction of a site (V Site) for this work; investigation of the need and possibility of heating equipment for the B-29 bomb bay.

7.87 In addition effort was devoted to the design and procurement of 23/59 scale Fat Man models for possible B-24 flight tests. Negotiations were started to obtain the use of the high-velocity Moffett Wind Tunnel for bomb ballistic experiments on the Fat Man. Although stable and statistically reliable Fat Man models were subsequently designed without this, only ballistic experiments under controlled conditions would have yielded definite information on the safety factors involved in these models. The necessary arrangements for this testing program proved difficult to make, and it was in the end deemed unnecessary.

7.88 During this period also two new bomb models were designed. DOE b(3)

DELETED DELETED DELETED

The length of this model was so reduced that it could be carried in a single B-29 bomb bay. When in midsummer the plutonium gun assembly was abandoned, it became unnecessary to join the bomb bays of the plane. The second model was the "1222" Fat Man model. This consisted of twelve petagonal sections of dural bolted together to form a sphere, and surrounded by an armor steel shell of icosahedral structure, with stabilizing shell attached. Mechanical assembly of this device required the insertion of some 1500 bolts.

7.89 The chief contribution of the Muroc tests in June was that although the Fat Man model tested was still unsatisfactory in its flight characteristics, field modifications, resulting from a suggestion by Capt. David Semple, USAAF (dec'd), to increase the drag, gave a stable model. This modification involved the welding of angularly disposed trapezoidal drag-plates into the box tail of the bomb. No release failures occurred, and the fusing mechanisms tested proved to have great promise.

7.90 In the period between these tests and the next held in October, design, procurement and testing work continued at Los Alamos. When by midsummer it became certain that the plutonium gun assembly would not be used, the remaining models were the Little Boy and the Fat Man. A new model Fat Man was developed

in this period, to improve flight characteristics and simplify mechanical assembly. This was the "1561". It consisted of a spherical shell made up of two polar caps and five equatorial zone segments, machined from dural castings. The assembled sphere was enveloped by an ellipsoidal shell of armor attached at the equator. The tail was bolted to the ellipsoid. The electrical detonating and fusing equipment was mounted on the sphere in the space between the sphere and the outer ellipsoid.

Experiments on the 10 gram scale also showed that UI_4 could be reduced with calcium metal using the same procedures as were used for the fluoride and chloride.

DOE b(3)

DELETED DELETED DELETED

Argon was used as an inert atmosphere in the bomb. The amount of iodine used and the heating cycles varied with each scale of reduction. It was found that magnesium oxide crucibles were the most satisfactory. Methods for the preparation of the several types of MgO crucibles were developed, the methods later being used by MIT for the routine preparation of the large scale crucibles.

DOE b(3)

DELETED DELETED DELETED

URANIUM ALLOYS

8.25 Alloys were sought which would have better physical properties for fabrication than the unalloyed metal. Beginning in November 1943, an intensive program was undertaken on the preparation of uranium alloys in various percentage compositions. Mixtures of uranium with molybdenum, zirconium, columbium and rhenium were obtained which indicated that many desirable properties could be produced in such alloys. In particular, extended investigation of the uranium molybdenum system showed that it had a much higher yield strength than pure uranium. The emphasis on this work, however, was not maintained and in the fall of 1944 most of the alloy research was dropped, as ordinary uranium was found to have adequate physical properties.

Plutonium Purification

8.26 The plutonium purification procedure, as distinguished from the more general chemistry of plutonium, was primarily the work of the Uranium and Plutonium Purification Group at Los Alamos. Early in October 1943, the first small quantities of plutonium arrived at the Laboratory and shortly thereafter

intensive work on stand-ins was initiated to permit the members of the Purification Group to determine and improve their techniques. The stand-ins used included uranium, cerium, lanthanum, zirconium and thorium. Uranium was used principally in the investigation of ether extraction methods; thorium and cerium were employed to test solubilities and purification by various precipitations. In metallurgical work, cerium trichloride was used as a stand-in for plutonium trichloride and in other small scale work cerium tetrafluoride was used as a stand-in for the corresponding plutonium salt.

8.27 The development of plutonium purification procedures is readily divisible into three parts: wet processing, dry processing and, by reason of the cost of the material, a recovery process. The intensity with which the division attacked the difficult problem of plutonium chemistry was rewarded by the complete development in the first period of the wet chemistry procedure finally used in large scale work. By August 1944, however, the dry process and recovery procedures had not been completely determined. The former was still in the formative stage of development and the latter, while satisfactory, was greatly simplified by later research (17.18-21).

THE WET PROCESS

8.28 The plutonium output from Clinton and later from Hanford was received at Los Alamos as a highly viscous mixture of decontaminated and partially purified nitrates. These nitrates consisted of about 50% +4 plutonium and 50% +6 plutonium. This material had to be dissolved out of its stainless steel shipping container, diluted and a sample removed for radio-assay purposes. This preliminary work generally required between three and four days and when completed permitted further processing by the wet purification steps. A wide variety of purification procedures were investigated. Early in 1944 the first tentative procedure involved a double sodium plutonyl acetate precipitation followed by a double ether extraction employing sodium nitrate as a salting-out agent. Potassium

bichromate was originally used to go from +4 to +6 plutonium ion, but this was soon superseded by sodium bromate plus nitric acid. For selective reduction from +6 to +3 plutonium, hydrogen iodide or potassium iodide in acid solution were used throughout the work.

8.29 The first major difficulty encountered was the need of a process to separate small amounts of uranium impurity from large amounts of plutonium. Various compounds such as carbonate, peroxide, fluoride, iodate and oxalate were investigated. The iodate $Pu(IO_3)_4$ was found to give 99.5 per cent removal in two precipitations with a selective reduction step, but it proved extremely difficult to convert this compound to sodium plutonyl acetate. Finally the precipitation of the +3 oxalate provided the solution to the problem and became an important part of all future processes.

8.30 The procedure as outlined gradually changed. Two oxalate precipitation steps were incorporated. An ether extraction and a plutonyl acetate step were dropped. By July 1944, completely enclosed one-gram and eight-gram apparatus was being set up, and the process known as the "A" process had taken form. This involved reduction to +3 oxidation state, oxalate precipitation, oxidation to +6 oxidation state, sodium plutonyl acetate precipitation, ether extraction from nitric acid and ammonium nitrate solution, reduction to +3 oxidation state, and a final oxalate precipitation. The process gave yields of about 95 per cent. The product was then turned over to the dry chemists as an oxalate slurry. The residue supernatants were returned for recovery.

8.31 The reason for the development of enclosed apparatus was primarily the plutonium health hazard (9.30).

THE DRY PROCESS

8.32 Since the conversion of the wet oxalates to the dry halide of plutonium led to a product which the metallurgists had to reduce to metal, there was collaboration between these groups in the attempt to settle on a suitable

compound for reduction. The tetrafluoride was decided upon in July 1944. The preceding investigations covered the range of most of the halides of plutonium (for calcium bomb reduction) and PuO_2 (for carbon reduction). Plutonous chloride and bromide were rejected because they were highly hygroscopic. The carbon reduction of the oxide was also dropped.

8.33 The preparation of the tetrafluoride underwent continual development and improvement during the course of the work of the Laboratory. It was prepared variously from the nitrate, oxalate and oxide by the use of anhydrous hydrogen fluoride. The conversion of the nitrate was poor, and research concentrated on the conversion of the oxalate and oxide. The final choice of the oxide occurred early in 1945, as did the final development of production methods (17.21).

RECOVERY OF PLUTONIUM

8.34 Except for the peroxide recovery method (17.22) all procedures were developed before August 1944, by the Recovery Group. Recovery was necessary from the supernatants of plutonium purification and from liners and slags of the metallurgists. From the supernatants the procedure involved concentration of the plutonium with subsequent purification. Reduction was made with sulphur dioxide followed by a precipitation with sodium hydroxide. Treatment with aluminum hydroxide as carrier brought down further amounts of plutonium. About one milligram per liter remained in solution, and these secondary supernatants were stored. Purification steps originally involved iodide reduction oxalate precipitation, oxidation ether extraction, sodium plutonyl acetate precipitation, iodide reduction, and a final oxalate precipitation. After these steps had been carried out, the purified product went directly to the dry chemists.

8.35 Work on liner and slag recovery showed quite early that complete solution would be necessary for good recovery. The major difficulty was to remove iodine and iodide ion before solution. The first method developed was

one of CCl_4 or sodium sulfite extraction for the I_2. Following this, liner and slag were dissolved in hydrochloric or nitric acid, followed by a precipitation of $Pu(OH)_4$ from a solution almost saturated with ammonium nitrate. This precipitation was carried out at a high enough hydrogen ion concentration to leave most of the magnesium (from the magnesia liner) in solution.

Plutonium Metallurgy

8.36 In March 1944 the first bomb reductions of PuF_4 and $PuCl_3$ were undertaken by the Uranium and Plutonium Metallurgy Group. This was the first direct metallurgical work with plutonium, although previous work had been done with stand-ins (8.22). Emphasis was placed at this time on the electrolytic method and chloride reduction.

8.37 Research on the physical properties of plutonium metal began in April 1944 and was to prove of major importance because of the unique physical properties of the metal. By May 1944 metal yields were over 80 per cent by a number of methods and the shift of interest to the stationary bomb reduction method began. Extensive work on remelting, as a final purification step, centered interest on the use of refractories which would not contain light element contaminants. This eliminated the usual refractory-materials. One of the principal refractory materials investigated in these studies was cerium sulfide (8.53).

8.38 Discrepancies found in the density of various metal samples produced the first hint of the existence of plutonium allotropes. By June, metal obtained from $PuCl_3$ using calcium as a reducing agent and subsequent remelting in cerium sulfide crucibles came within a factor of ten in meeting the prevailing purity specifications. The alpha and beta allotropes of plutonium were definitely established at this time and the PuO_2 plus carbon reduction method developed in the High Vacuum Research Group came into temporary prominence.

PLUTONIUM REDUCTION

8.39 As with uranium, two general methods of metal preparation were investigated; the electrolytic process and the metallothermic process. The latter process was again divided into two methods; the centrifuge method and the so-called stationary bomb method. An additional method was also studied in which the oxide of plutonium was reduced and the metal distilled.

DELETED DELETED DELETED

DOE b(3)

8.40 Electrolytic Process: Investigations of the electrolytic reduction of plutonium on the 50 mg-1 gram (of metal) scale gave recovery yields of ~50 percent. The bath consisted of 24 percent $PuCl_3$ in a solvent containing 48 percent $BaCl_2$, 31 percent KCl, and 21 percent by weight of NaCl. The metal obtained was in the form of droplets and usually contained small amounts of the cathode element. With the discovery of Pu^{240}, the work on the electrolytic process was stopped in favor of the metallothermic process. Details of the electrolytic process are given in La-148.

8.41 Centrifuge Reduction Method: As in the case of uranium (8.24), the purpose of this method was to prepare plutonium metal on the small scale (50 mg-1 gram of metal) by taking advantage of the increased g value for the collection of the small amounts of metal. Successful reductions of plutonium were made using $PuCl_3$ or PuF_4 with Li as a reductant. Calcium reductions of these halides using iodine as a booster were not as successful. The plutonium metal prepared by the centrifuge method was the first plutonium metal prepared on any scale larger than a few micrograms. With the development of the 0.5 gram scale stationary bomb method for the preparation of plutonium, the centrifuge method was abandoned. However, the centrifuge served its purpose at a time when it was needed most. (Appendix 7 , No. 27).

8.42 Stationary Bomb Method: The work on this problem was started in March 1944; however, much preliminary work had already been done using uranium as a stand-in. As in the case of uranium, the problem of plutonium reduction involved the development of refractory crucibles for the reaction, the design of suitable bombs, the investigation of raw materials for the reaction, and the development of techniques of each scale of reduction studied. During the research on plutonium, cerium and lanthanum were also used as stand-in elements, and techniques were developed to prepare both metals from their chlorides and fluorides on all the scales given below. The chloride of plutonium was used for the first successful reductions of plutonium by the stationary bomb method. These reductions were done on the 0.5, 1, and 10 gram scale. The fluoride was then investigated and found to be more satisfactory because of its non-hygroscopic nature and greater ease of preparation. Successful techniques were developed for the reduction of plutonium on the 0.5, 1, 10, 25, 160, 320, and 480 gram scales. The average yields in a single button of clean metal ranged from 95% for 0.5 gm, to 99% for the 320 and 480 gram scales. The bromide was also reduced on the 1 gram scale, but with lower yields. The methods developed here from the reduction of PuF_4 are now used for the routine production of pure plutonium metal. (Appendix 7 , No.28)

8.43 The oxide reduction method involved the reduction of plutonium oxide with carbon or silicon and distilling the resulting metal onto a cold finger. This method gave yields on a small scale (5 gram) of 30 to 90 percent of spectroscopically pure plutonium. The discovery of Pu^{240} called a halt to this ultra-high purity method.

8.44 In addition to reduction techniques, remelting techniques were also investigated. A large part of this work was in the choice of crucible materials. Remelting was important because of the need for metal with uniform physical properties and because further impurities (e.g. magnesium) were removed in the process.

8.45 Extensive work was carried out by the Los Alamos metallurgists on the physical properties of plutonium metal. Early results yielded inconsistent data from measurements on different metal samples. In July 1944 these inconsistencies were partially explained by proof of the existence of alpha and beta allotropes, with a transition from the room-temperature alpha phase to the beta phase at between 100-150° C.

Miscellaneous Metallurgy

8.46 A good deal of outstanding metallurgical work was done at Los Alamos outside the narrow field of uranium and plutonium, principally by the Miscellaneous Metallurgy Group. Many of the jobs undertaken were more or less routine, but these routines had to be developed through the solution of difficult minor problems. The development of uranium hydride compacts has been discussed in connection with uranium metallurgy (8.19-21). Work on the compacting of boron neutron-absorbers was undertaken in August 1943. Development of beryllia tamper material for the water boiler was begun in the same month. The formation of high-density beryllia bricks for this became a production job in December 1943 and was completed in February 1944. DELETED DELETED DELETED In May, because of the difficulties encountered in obtaining refractories from other sources, magnesia liners and cerium sulfide crucibles were developed for the plutonium metallurgy program.

BORON COMPACTS

8.47 The remarkable properties of boron^{10} as a neutron absorber gave this material several uses in the laboratory. DELETED DELETED DELETED The potential importance of boron^{10} was such that its procurement was undertaken quite early (4.20), and studies were begun of means of compacting it. The oxide, the carbide and the element were used as starting materials. DELETED DELETED DELETED

DOE b(3)

DELETED DELETED DELETED

BERYLLIA COMPACTS

8.49 One of the accomplishments of the Miscellaneous Metallurgy Group was the development and production of beryllia bricks for the water boiler tamper and scattering experiments. Since these bricks were to be used as tampers high density was desirable. Beryllium metal would have been the best tamper material. Use of the metal at that time, however, would have virtually exhausted the country's supply.

8.50 Various methods of obtaining high density were tried, among them impregnation with magnesium fluoride but the fluoride was undesirable from a nuclear point of view. A method of impregnation with beryllium nitrate followed by ignition proved rather poor.. The method finally chosen was a hot pressing technique, somewhat unusual for a refractory material.

8.51 Experimentally, the bricks were prepressed in a steel mold, then hot pressed in graphite at 1700° C at pressures in the neighborhood of 1000 pounds per square inch for five to twenty minutes. Fifty-three bricks were made for the water boiler tamper, shaped to fit around the 12-1/16 inch sphere of the boiler. For this production job the method was a variation of the method described above. The density averaged 2.76.

DOE b(3)

DELETED DELETED DELETED

CRUCIBLE AND REFRACTORY RESEARCH

8.53 The purpose of this important work was to find materials for

crucibles and liners which would not introduce contaminants into purified uranium and plutonium. Wetting, sticking and thermal sensitivity had also to be considered. In this program a great many substances were investigated including cerium sulfides, calcium oxide, magnesium oxide, tantalum, graphite, a tantalum-thorium nitride mixture, zirconium nitride, thorium sulfides, beryllia, uranium nitride, thoria, tungsten carbide, tantalum carbide, titanium nitride and many others. Cerium sulfide was one of the really hopeful materials found during this period and effort was concentrated on trying to improve the fabricated material's resistance to thermal shock, its main weakness.

DOE b(3)

DELETED DELETED DELETED

MISCELLANEOUS SERVICE ACTIVITIES

8.54 The metallurgists prepared a great variety of materials for physics and ordnance experiments. These involved machining, heat treating, metallographic studies, casting of various metals, electroplating, miscellaneous plastic preparations and powder metallurgy. Metallographic methods for uranium and plutonium studies were essentially new. This work was done mainly by the Heat Treating & Metallography Group, and the Miscellaneous Metallurgy Group.

Radiochemistry

8.55 Prior to August 1944 the work of the Radiochemistry Group fell into the following categories: foil preparation, boron trifluoride preparation, development of sensitive methods of neutron detection, the chemistry of initiators, the chemistry of the water boiler and the planning of remote control methods for the handling of radio-lanthanum.

FOIL PREPARATION

8.56 The preparation of thin foils for physical experiments was a service activity but, as such, involved a great deal of arduous and delicate work, and continued research on methods. Foils of a large number of different

substances were made with emphasis on the oxides of uranium and plutonium. Among other substances were boron, protoactinium, uranium 233, neptunium 237 and thorium.

8.57 The principal methods of foil preparation used were evaporation, electrodeposition and the "lacquer" method, -- the last so-called because in it an alcohol metal salt solution is mixed with a nitrocellulose lacquer, spread in a thin film, and ignited to oxide.

8.58 Boric oxide foils were prepared by the lacquer method. Aluminum boride foils were prepared by heating aluminum foils in boron trifluoride. Boron was deposited on tantalum and tungsten foils by thermal decomposition of diborane. This work with boron was exceptionally difficult, requiring the production of very thin foils with accurately known mass. It was developed by Horace Russell, Jr. (deceased). Deposits of the oxides of thorium, uranium and plutonium were prepared by the lacquer technique, as well as by electrolytic methods.

8.59 The virtuosity of the chemists engaged in this work was remarkable. They turned out large numbers of foils that accurately met the physicists' specifications, including unusual geometries. In many cases the data supplied with the foils by the chemists were as important in interpreting physical experiments as any of the physical measurements made with them.

CHEMISTRY OF INITIATORS

8.60 It was assumed from the beginning that a neutron initiator would be used with the bomb to provide a strong neutron source that would operate at the instant of optimal assembly. Naturally, the first initiators were designed for the gun (7.40). The type of initiator, if any, to be used with the implosion was not settled until after August 1944. The principal mechanism adopted for the initiator was the properly timed mixing of alpha-radioactive material with a substance that would support the (α ,n) reaction.

SENSITIVE COUNTERS

8.61 The radiochemists developed a neutron counter based upon the Szilard-Chalmers reaction. In this reaction a nucleus absorbs a neutron. It then loses energy by gamma emission and the recoil of the atom frees it from its chemical bonds. This dissociation permits the chemical separation of the reaction product and the measurement of its induced radioactivity. The sensitivity of this reaction as a neutron counter is high because it permits the absorption of neutrons in a large volume of material. Until early 1944 ethylene bromide was used as the basis of the procedure. At that time work began with potassium permanganate. A detection efficiency of about ten per cent was eventually obtained.

8.62 Sensitive boron trifluoride counters were developed cooperatively by the Radiochemistry Group and the Radioactivity Group. It was the job of the

radiochemists to prepare this substance in an extremely pure form. High purity of the product made possible effective operation at high boron trifluoride pressures. The first such counter, the "bucket chamber", had a one or two per cent efficiency. Later, the radiochemists developed another counter themselves (17.37).

WATER BOILER CHEMISTRY

8.63 Since the water boiler contained active material in aqueous solution, there were a number of chemical problems associated with the physical ones. The choice of a compound to use, the original purification of the material, the prevention of corrosion of the containing sphere, and methods of decontamination and analysis were the main matters requiring investigation.

8.64 In the original boiler it was decided to use uranyl sulfate for the following reasons: the solubility and solution density were higher than those of the nitrate; there was, moreover, some saving in critical mass because the neutron capture cross-section is smaller for sulfur than for nitrogen.

8.65 Purity requirements were not strenuous except for two or three light elements. They were calculated by the rule that no impurity in the solution should absorb more slow neutrons than the sulfur in the sulfate.

8.66 Work on corrosion determined that stainless steels were suitable for boiler container and piping. The effects of working, welding and annealing were studied and it was shown that weight loss dropped to zero after a few days time. Boiler parts were therefore pretreated with normal isotopic uranium sulfate solution and corrosion difficulties were substantially eliminated.

8.67 The hydrates of uranyl sulfate were investigated in order to predict volume changes from final additions of active material to the boiler "soup". A stable hemi-hydrate was found with less water than the normal precipitate from saturated solutions.

8.68 The refractive index of uranyl sulfate solutions was investigated

to develop a rapid method of keeping track of amounts of uranium in solution. With monochromatic light through pure solutions, concentration would be measured to 0.1 per cent.

8.69 In the actual setting up of the boiler in May 1944, the chemists made all additions and removals of "soup", keeping accurate records of concentration by the refractive index and by gravimetric analysis method. When the activity of the boiler reached the critical point the concentration was measured by refractrimetry and checked by other methods. The control rod was calibrated by adding small weighed increments of sulfate and determining the critical setting of the control rod for each increment.

RADIOLANTHANUM

8.70 Before August 1944 no test shots were fired in the RaLa program (7.74). Design of a "mechanical chemist" for remote control work with this highly radioactive material began, however, as early as May 1944. By August the apparatus, at the Bayo Canyon site, was almost complete. Further account of this work is found in Chapter XVII.

Analytical Methods

8.71 The high purity analytical program was organized on the basis of theoretical considerations already reported (1.73). The plan to use plutonium originally demanded an extremely low rate of neutron emission, estimated to be 3 neutrons per minute per gram. Tolerance limits for each element were calculated by polonium alpha-particle bombardment of element targets and calculation of the neutron yield, thus obtaining the amount of element necessary to give 3 neutrons per minute.

8.72 The tolerance limits for 13 elements, not counting the rare earths, were found to be below 100 parts per million. In addition, effects are additive. It was generally agreed that the sensitivity of analytical methods should be one tenth of tolerance. Since early experimental production would be very small, and analytical samples might well be no larger than 1 milligram, it

was evident that research on new submicro-analytical methods was necessary.

8.73 In general, high sensitivity was sought rather than high precision. The analytical chemist's greatest difficulty was to identify and determine approximately the interfering elements. When this was done the purification procedure could be modified to eliminate such elements or at least cut them down considerably.

8.74 Unusual factors entered into such submicro work. Reagents had to be unbelievably purified in order that the presence of a particular impurity should not become the limiting factor of the method. Contamination was probably the major difficulty since most of the worst elements are prevalent in any ordinary experimental environment (atmospheric dust and fumes, floor scuffings, etc.). The laboratories were equipped with precipitrons. Floors and walls were kept very clean. A special sub-group of the CM-1 Service Group was devoted to light element contamination control and investigation. Theirs was the job of making certain that dust in laboratory air was at a minimum and that laboratory personnel were not unconsciously causing some significant contamination. Control tests were run on dust deposition in the laboratories; the humidifying system was found to bring in contamination and was stopped. Shoe covers were adopted to avoid floor scuffing and methods of cleaning floors were improved.

8.75 Some of the analytical methods used at Los Alamos were developed at the Chicago Metallurgical Laboratory. Rather close liaison existed between the two projects in this particular field. One of the outstanding analytical developments at Los Alamos was the vacuum method for carbon and oxygen analysis.

8.76 The analytical methods involved in the early work at Los Alamos may be divided into the following categories:

1. Spectrochemical Methods.

   A. Plutonium

(1) The cupferron and gallic acid methods--trace analysis for light element impurities.

(2) The direct copper-spark method.

B. Uranium

(1) The gallium-oxide-pyroelectric method.

(2) Determination of rare earths in uranium.

(3) Cupferron precipitable refractories in uranium.

C. Miscellaneous

(1) Impurities in graphite by gallium-oxide-pyroelectric method.

(2) Determination of fluorine in uranium and calcium (the strontium fluoride band method).

2. Colorimetric Methods.

A. Determination of phosphorus in uranium and plutonium.

B. Determination of microgram quantities of acid soluble sulfide sulfur.

C. Determination of iron in plutonium.

D. Determination of sub-microgram quantities of boron in calcium, uranium and plutonium.

3. Gravimetric Methods.

A. Determination of molybdenum in uranium-molybdenum alloys.

B. Determination of carbon in uranium tetrafluoride..

4. Assay Methods.

A. Radioassay.

B. Photometric assay.

5. Gasometric Methods.

A. Oxygen.

B. Carbon.

1. SPECTROCHEMICAL METHODS

8.77 These methods were developed by the Analysis Group. Copper electrodes for use with spark excitation had been used at Berkeley in the first spectrochemical analysis of plutonium. The direct copper spark method as used at Los Alamos was a Chicago development. It had been shown at Chicago that plutonium could be extracted by cupferron and chloroform. The method of making this separation before sparking was conceived at Chicago but developed at Los Alamos. The pyroelectric-gallium-oxide method was developed at Los Alamos.

A. Plutonium analysis

8.78 The cupferron and gallic acid methods were first used (early 1944) as co-methods in developing routines for trace analysis of the light elements. The former was chosen as standard. When, in August 1944, purity standards were relaxed, the need for very sensitive methods disappeared and further research on their improvement ended. The cupferron method is discussed in Chapter XVII.

8.79 The direct copper spark method was used throughout the Laboratory history. In this procedure plutonium is evaporated on copper electrodes and the spark-spectrum photographed in the 2500-5000 angstrom range. The quantities of impurities are estimated by measurement of spectral line densities. By the end of this history, this was the only method available for the determination of thorium and zirconium. It was used for preliminary determination of impurities in incoming Hanford plutonium solutions.

B. Uranium analysis

8.80 Except for a short time early in 1944 when the gallic acid method of analysis was tried for a while, the pyro-electric method was the means of overall purity analysis of uranium. In this method the oxide mixed with gallium oxide is arced from a crater in a graphite electrode and estimates are made spectrographically. Volatilization of impurities along with gallium occurs in a manner analogous to steam distillations but the complex uranium spectrum

does not appear. Volatile compounds lost in ignition to the oxide are not determinable.

8.81 Rare earth determination of high sensitivity was made possible by a method which removed other impurities, followed by examination of the spark spectrum.

8.82 Cupferron-precipitable refractories --titanium, zirconium and iron-- were separated from other impurities by this method and examined in the copper spark.

C. Miscellaneous

8.83 Graphite purity analysis was developed as an adjunct of the PuO_2 graphite metal reduction (8.42) and dropped with the latter.

8.84 The strontium fluoride band method was the only successful method discovered for fluorine analysis. This method involved the absorption of fluorine in sodium hydroxide. The sodium fluoride is arced in the presence of excess strontium oxide and the amount of fluorine estimated by comparing strontium fluoride band head intensities with a standard. This method seems applicable to a number of materials but at Los Alamos has only been applied to uranium and calcium.

2. COLORIMETRIC METHODS

8.85 Phosphorus in uranium and plutonium was estimated by a colorimetric method depending on the formation of molybdenum blue from orthophosphate.

8.86 Microgram quantities of acid-soluble sulfide were estimated by a colorimetric method. This depends upon the conversion of hydrogen sulfide into methylene blue, which is determined spectrophotometrically.

8.87 Iron was determined spectrophotometrically in the presence of + 3 plutonium after reduction to the ferrous state with hydroxylamine.

8.88 Boron in calcium, uranium tetrafluoride and plutonium were determined by distillation as methyl borate from a special quartz still. The distillate was trapped in calcium hydroxide solution and the boron estimated by a colorimetric method.

3. GRAVIMETRIC METHODS

8.89 Gravimetric methods were used for the determination of molybdenum in uranium-molybdenum alloys and of carbon in uranium tetrafluoride.

4. ASSAY METHODS

8.90 Before August 1944 radioassay was the means of keeping track of plutonium quantities received, while a true analytical method, photometric assay, was being investigated. This method, however, did not yield encouraging results and was later proved quite untrustworthy. Hence, radioassay was continued. This method involved the determination of the quantity of an aliquot of the material by measurement of its alpha activity.

5. GASOMETRIC ANALYSIS

8.91 Description of the procedures involved in this work is limited by the extreme complexity of the apparatus used. The apparatus used for oxygen and for carbon micro-determinations can be classed among the most complicated analytical set-ups in the history of chemistry.

8.92 The oxygen method developed by the High Vacuum Research Group solved one of the most pressing analytical problems at Los Alamos --the development of a dependable micro-method for oxygen determination. The overall method was not new but its application on a micro-scale, the accuracy obtained, and the furnace tube developed were quite new.

8.93 The procedure involved vacuum fusion of a sample in a graphite crucible and analysis of the gases evolved. Oxides react with graphite at high temperatures, giving carbon monoxide. Determination is made of this compound.

8.94 The apparatus was composed essentially of two parts, a high vacuum system (10^{-8} centimeters) and a somewhat revised Prescott microgas analyzer. Either one of these systems could be broken from the line independently. The sample size was about 50 milligrams and sensitivity of the method was about ten parts per million. In the original procedure the crucible and furnace tube were put in place, the sample was put in a dumper bucket, and the tube sealed. The sample was dropped into the crucible after the latter was suitably degassed. The gas was then collected for analysis.

8.95 The apparatus for carbon analysis in plutonium was simply a modification of the oxygen apparatus. The sample was burned in oxygen from mercuric oxide in a low-carbon platinum crucible. The gaseous products were then analysed by the Prescott apparatus. In this case the sensitivity was five parts per million or less.

CRYOGENY

8.96 At the very beginning it had appeared that the development of a deuterium super-bomb might prove feasible and necessary during the wartime course of the Laboratory. As the great difficulties attending this development became more apparent, and as the energy of the Laboratory was absorbed in the prior problem of the fission bomb, the experimental side of the "Super" project was gradually brought to a standstill. Except for new cross section measurements later made in F Division (13.38) this program was in fact limited from the beginning to investigation of the preparation and properties of liquid deuterium. Locally, it was virtually limited to the design and construction of a deuterium liquefier. This was a Joule-Thompson liquefier patterned after that built by W. F. Giauque at the University of California. It consisted of an ethane, a liquid air, and a liquid hydrogen (or deuterium) cycle. The first two cycles were completed by the beginning of 1944. The hydrogen cycle was completed in April 1944 and tested. Although the original design was for a

capacity of 35 litres an hour, at the altitude of Los Alamos (7300') it produced only 25 litres, a loss which could be compensated for by additional compression if necessary.

8.97 Because of limitations of space and personnel, the physical investigations relevant to the problem of producing and storing liquid deuterium were carried out under contract by Prof. H. L. Johnston at Ohio State University. These included studies of the ortho-para conversion of liquid hydrogen and deuterium, of hydrogen-deuterium exchange problems, of the high-pressure low temperature equation of state for hydrogen and deuterium, of the heat of vaporization of liquid deuterium, of the Joule-Thompson coefficients of hydrogen and deuterium. Experiments were made on the properties of thermal insulators at low temperatures. Studies were also made of the long-term operation of hydrogen liquefaction equipment.

8.98 Work was begun under the Ohio State contract in May 1943, and continued through the life of the Project. The contract was renewed at six month intervals. As of September 1945, investigations still incomplete were planned for completion by the end of that year.

8.99 After the first test of hydrogen liquefaction in April 1944, no further developments in cryogenic work occurred at Los Alamos. Long and his group were assigned to other problems. On the basis of his assurance that with existing equipment he could produce amounts of the order of 100 litres of liquid deuterium in two months, and amounts of the order of 1000 litres in eight months, cryogenic work was formally suspended in September 1944.

Chapter X

THE PERIOD AUGUST 1944 - AUGUST 1945

TECHNICAL REVIEW

Introduction.

10.1 As the previous chapter will testify, the growth of the Laboratory plant and program during the period reviewed was determined primarily by the urgency and difficulty of the implosion program. The status of that program at the end of the previous period has been outlined in Chapter IV (4.46-4.53). By comparison of this situation with that existing in July, 1945, when the first implosion bomb was tested and found successful, it is clear that by the latter date a major technological victory had been won. The period reviewed, however, is not completely defined by that victory. The success of the Trinity test was possible only in the flowing together of several parts of the Laboratory's work. The success of the combat missions over Japan, moreover, presupposed that of the entire delivery program. Finally, it must not be forgotten that the first atomic weapon was the "Little Boy" gun assembly, developed during this period largely by a single group. Because it was relatively smaller and more straightforward than the implosion, its accomplishments will be reviewed first.

Gun Program.

DOE b(3)

10.2 During this last year of the war the gun program was consolidated under one group, the Gun Group of the Ordnance Division. This group completed the design of the U^{235} [redacted] gun assembly, tested its components at reduced and full scale, undertook their final engineering and procurement, and after an elaborate program of final field and drop tests produced a weapon more certain of high-order operation, without having been tested, than the more radical implosion design tested at Trinity. During the earlier period of the Laboratory

the possibility of a U^{235} implosion bomb had not been ruled out. With the acquisition of accurate means of calculation and reliable cross section data, it became evident that such an implosion would be considerably less efficient than the plutonium implosion. This fact, added to the uncertainties of the whole implosion program, made it seem desirable to plan for the use of U^{235} by the gun method alone. Toward the end of the war the possibility of composite (U^{235} + Pu^{239}) implosion bombs was considered (11.2, 20.2). By the time of the "freeze" of the Laboratory program in February, 1945 (11.16), the decision was final to use U^{235} only in the gun model.

10.3 This quiet and efficient group continued at the center of an affiliated program in the Research Division, the Theoretical Division, other groups of the Ordnance Division, and in the Alberta Project (Ch. XIX). From the Research Division, Group T-2 was able to obtain information on the nuclear properties of U^{235} [redacted] sufficient to provide accurate data for critical mass calculations and calculation of the amount of material that could be safely used. From the sphere multiplication experiments of R Division a still more accurate calculation of the critical mass could be obtained, by extrapolation. The gun was "mocked" by the model experiment in the same division, and this provided an integral check of the calculations of the performance of the weapon, including predetonation probability. The finished projectile and target, finally, were brought to the critical point by the Critical Assemblies Group of G Division shortly before shipment to Tinian for combat use. This assembly was a final check of the accuracy of predictions as to the point at which the system would become supercritical. Reliable efficiency calculation was made possible by theoretical and experimental estimation of the initial multiplication rate of the fully assembled bomb.

DOE b(3)

10.4 The fabrication of the projectile and target was the responsibility of members of Groups CM 2,7, and 11 of the Chemistry and Metallurgy Division.

DOE (b) (3)

Fabrication included the forming of the active material into pieces of proper shape and purity [DELETED] [DELETED] and the steel casing that housed the target. The development of the initiators used to assure an initial neutron source was the work of the Gun Group in collaboration with the radiochemists. The final design of the outer case, originally the responsibility of the Engineering Group of the Ordnance Division, was almost entirely transferred to the Gun Group during this period. Responsibility for the fusing and detonating system remained with the Fuse Group of the Ordnance Division. The Gun Group and the Fuse Group collaborated in the drop tests of the "Little Boy" carried out as part of the program of Project Alberta.

The Plutonium Bomb

10.5 At the beginning of the period under discussion the hope for a successful implosion was so low that F Division was given the responsibility, soon after its creation, of investigating even the slim possibility that as an alternative, an autocatalytic system of assembly utilizing plutonium might be found meritorious. The desirability of such systems was not immediately evident and in the meantime the Weapon Physics Division, the Explosives Division, and the Theoretical Division were preparing themselves for a direct attack on the implosion problem.

DOE (b) (3)

10.6 Prediction based on the analysis of Clinton plutonium led to the expectation that the Hanford plutonium would produce [DELETED] neutrons per second in bomb-amounts of plutonium, from the spontaneous fission of Pu^{240} alone. Light impurities would produce additional neutrons, but purification would keep this contribution small compared to that from spontaneous fission. Only the implosion would be fast enough to assemble the plutonium in a time short enough to avoid predetonation.

10.7 The "direct attack" on the implosion problem included the continuation of small scale implosion studies in the new X Division, with particular emphasis on interpreting the causes of jets and irregularities,

including the careful investigation of the source of timing errors in multi-point detonation and their contribution to asymmetries. The first lens test shot was fired in November, 1944. In the meantime G Division was getting under way its many-sided effort to examine the implosion experimentally, was beginning work on electric detonators, and was planning the hydride critical experiments as a step to eventual critical assemblies of active metal. At the same time the Theoretical Division was completing its studies of the "ideal" implosion (which began with a spherically converging shock-wave), and was turning its attention to the theoretical interpretation of the jets and asymmetries that had been found in less-than-ideal experimental implosions.

10.16 At the end of February, 1945, a conference was held at Los Alamos, with General Groves present, at which it was decided that the time had come to freeze the program of the Laboratory in order to meet the July deadline for the first bomb test. At this conference it was decided to concentrate all

further work on the solid core lens implosion with a modulated nuclear initiator. DELETED DELETED DOE b3) DELETED DELETED

10.17 At the same time a detailed schedule of all implosion work was decided upon. DOE b3) DELETED DELETED DELETED By April 2 full scale lens molds had to be delivered and ready for full scale casting. Full scale lens shots had to be ready by April 15, to test the timing of multipoint electric detonation. Hemisphere shots had to be ready by April 25. The DOE b3) detonator DELETED had to come into routine production between March 15 and April 15. By the latter date large scale production of lenses for engineering tests had to be begun. A full-scale test, by the magnetic method, had to be made between April 15 and May 1. Full scale plutonium spheres had to be fabricated and tested for their degree of criticality between May 15 and June 15. By June 4 the fabrication of highest-quality lenses for the Trinity test had to be under way. The Trinity sphere fabrication and assembly should begin by July 4.

10.18 To meet the stringent requirements of this program, the Cowpuncher Committee (9.8) was set up March 1, to "ride herd" on it. DOE b(3) DELETED DELETED DELETED

DOE b(3)

DELETED The feasibility of a modulated initiation was accepted April 27. DELETED DELETED DOE b(3)

DOE b(3) DELETED Full scale lens molds were completed in May, after innumerable procurement delays. Timing measurements of lenses were made with successful results shortly thereafter, but also delayed. DELETED

DOE b(3) DELETED DELETED At the beginning of June the first "urchin" initiator DELETED filled with DELETED DOE b(3)

DOE b(3) polonium. By June 12 two full scale plutonium hemispheres were tested for neutron multiplication, something over two weeks late. The delays referred to arose primarily because of the difficulty of procuring good lens molds on schedule. The result was a shortened time for final engineering tests. But the Trinity test was made, actually four days ahead of the target date - July 20, 1945 - assumed in making the above schedule.

Theoretical & Experimental Physics

10.19 During the period reviewed the Theoretical Division was able to bring to a successful close its earlier investigation of the techniques for solving neutron diffusion problems with accuracy, reliability, and speed. The Division developed these techniques and similar refinements in the means of treating the other theoretical problems involved in the implosion and the nuclear explosion. It was therefore able to give realistic guidance to the last phase of the experimental program, to the final weapon design, and to the preparations for the Trinity Test. In F Division the investigation of the Super continued at relatively low priority until the end of the war, when the freeing of men from other work made it possible to bring this work to partial completion. The results obtained indicated, in a convincing but not decisive way, that such a weapon is indeed feasible.

10.20 The experimental program in nuclear physics was continued by Divisions R and F. In R Division the original program of differential measurements was brought to completion: Neutron number measurements, spontaneous fission measurements, measurement of the fission spectrum and of fission cross sections, and scattering cross sections. Increasing emphasis was put on integral experiments, including tamper measurements and integral multiplication experiments, using solid spheres of U^{235}. In F Division, meanwhile, new measurements were made of the deuterium and tritium cross sections, which indicated a materially lower ignition temperature for tritium-deuterium mixtures than had been first obtained. The development of the high-power water boiler was carried through, and the instrument put into routine operation as a neutron source. Other work of the Division included cooperation with R Division on sphere multiplication experiments, and the preparation for radiochemical measurements at the Trinity test.

10.21 In G Division the Critical Assemblies Group carried through a program of critical assemblies with uranium hydrides of various compositions, and finally undertook the task of making metal critical assemblies with active materials to be used in the first bombs.

Chemistry and Metallurgy

10.22 The period under review saw, in the Chemistry and Metallurgy Division, the bringing to completion of full scale process and plant design, and full scale plant operation for production of active and tamper materials of both the U^{235} gun model and the Pu^{239} implosion model bombs. In addition to this the processing and handling of highly radioactive materials was carried out, both for the RaLa implosion test program and the neutron initiator program (polonium). As already pointed out the basic research program, plutonium purification, had already been solved on the research level by the time of the

discovery of Pu^{240} and the relaxation of purity requirements entailed by that discovery. The development of an efficient purification scheme was completed in the present period, as were the necessary techniques of metal reduction and metal forming. DELETED DELETED DELETED

10.23 The work of the Chemistry and Metallurgy Division, which in addition to the main program outlined above continued to do a great variety of service work for other divisions, was hampered by serious hazards to personnel from plutonium and polonium toxicity, and developed an elaborate system of monitoring buildings and examining employees. This health control work was hampered by increased crowding of facilities, until new plant facilities were made available.

The Trinity Test

10.24 The planning of the Trinity test became a high priority program in March, 1945. The Jornada del Muerto site for the test, called Trinity, had been selected in the previous Fall, necessary road and building construction had been undertaken, and a Military Police detachment had taken up residence at "Base Camp" in December 1944. Although most parts of the Trinity program were under way in March, there was a vast amount of work still to be done, in planning and instrumenting the great variety of mechanical, optical and nuclear records that had to be obtained. Several square miles of desert became the habitat of a complex laboratory, tied together in one vast system by thousands of miles of electrical wiring.

10.25 The first aim of the Trinity project was the rehearsal shot of 100 tons of high explosive that took place early in May. This provided a test of the organization for the final shot, and gave data for the calibration of blast measurements.

10.26 The information gained from this trial run proved valuable for the larger job ahead. As the July deadline of the test approached, larger and larger contingents of personnel arrived from Los Alamos to make ready the equipment for firing the bomb, for recording measurements of blast and shock, of spectographic and photographic information, and of nuclear data. The two hemispheres of plutonium were delivered from Los Alamos on July 11, and assembly of the high explosives began July 13.

10.27 The first atomic explosion was set off on the morning of July 16 after weeks of intensive preparation, and hours of tense waiting to see if the weather, which had turned bad the night before, would clear. The event can hardly be summarized more concisely than in 18.26 - 18.28.

10.28 With the impressive success of the Trinity test--whose yield certainly exceeded the expectations of most people, and was soon estimated to lie in the range 15,000 - 40,000 tons of TNT--the machinery of Project Alberta, the overseas mission, began to operate. Since the history of this project is largely an account of its test program, its liaison arrangements and general administration, the present technical summary ends with the successful completion of the Trinity program.

Chapter XI

THE THEORETICAL DIVISION

Introduction

11.1 During the second period, from August 1944 to August 1945, the Theoretical Division took part in the general expansion of the Laboratory to the extent of increasing the size of its groups, and adding three new Groups. In comparison with other divisions it had relatively little administrative history. It was not seriously involved with the general Laboratory problems of personnel, construction, transportation, nor was it involved except in an advisory way with the complicated procurement and scheduling operations of the Trinity test and Project A. It was therefore able to administer itself and do its work rather unobstrusively. Nevertheless it was an essential part of the final development program. As it gathered power from its earlier work, it was able to handle more realistic and complex problems with increasing efficiency, and to gain increased understanding of the difficult hydrodynamical questions involved in the implosion and the nuclear explosion, to refine its earlier calculations concerning critical masses and efficiencies, and to provide reliable interpretation of many integral experiments.

11.2 The Group Structure of the Division by August, 1945, was as follows:

T-1.	Implosion Dynamics	R. E. Peierls
T-2.	Diffusion Theory	Robert Serber
T-3.	Efficiency Theory	V. F. Weisskopf
T-4.	Diffusion Problems	R. P. Feynman
T-5.	Computations	D. A. Flanders
T-6.	IBM Computations	E. Nelson
T-7.	Damage	J. O. Hirschfelder
T-8.	Composite Weapon	G. Placzek

11.3 Group T-6 was added in September, 1944, to operate the IBM machines, under S. Frankel and E. Nelson. Frankel left this group in January

1945 to join the Theoretical Group of F Division. Group T-7 was formed in November, 1944, by a change of name. It was the Former O-5 Group, already for practical purposes a part of the Theoretical Division. At the time of this formal change of status, however, the group was given the responsibility for completing earlier investigations of damage and of the general phenomenology of a nuclear explosion. Group T-8 was added in May 1945 upon the arrival from Montreal of G. Placzek. The responsibility of this group was to investigate future fission bomb possibilities, specifically the levitated and composite core implosion, intended to use U^{235} (with Pu^{239}) more efficiently than would be possible by gun assembly.

Diffusion Problems

11.4 Although by August 1944 the essential difficulties of the one-velocity diffusion problem had been overcome, even the most economical method (expansion of the neutron distribution in spherical harmonics) was still rather expensive. A very great simplification of these calculations was accomplished by Group T-2 in the Fall of 1944, when an analytical expression was developed which by comparison with previously computed critical radii gave accuracies within 1-2%. This method made use of simple solutions for the shape of the neutron distribution far from boundaries (such as the boundary between core and tamper), and then fitted these solutions discontinuously at the boundary in such a way that the critical radius was given. From this time on, solutions for a great variety of critical radius or mass problems were proliferated extensively, and even reduced to nomographic form, permitting very rapid calculation.

11.5 Throughout the period under review various groups in the Theoretical Division, but particularly T-2, were concerned with special problems arising out of sphere multiplication experiments carried out in R Division.

These calculations had to take into account the variation of the average cross sections after the initial and each following collision of neutrons emerging from a central source. The number of neutrons coming out of the sphere as a function of the number of source neutrons was calculated for various size spheres and for various dispositions of the source. These calculations agreed very closely with the measured values; and as larger spheres of U^{235} became available, it was possible to extrapolate to the critical mass with very high accuracy (12.18-12.23).

11.6 Critical mass calculations for the hydride were developed, by Group T-4, as a means of predicting the size of the hydride critical assemblies carried out by Group G-1 of the Weapon Physics Division. When the first assemblies were made, a sizable discrepancy between the actual and the predicted critical size was found, of the order of 50%. Efforts to track down the cause of this discrepancy were partially successful; when newer values for the fission spectrum were used, the discrepancy was materially reduced. The conclusion was reached that the discrepancy arose from the sensitivity of the calculations to experimental errors in nuclear constants employed, and not from errors in the theory. This however was not certain, and some doubt was cast upon the adequacy of the methods employed. Hydride calculations, fortunately, were much more complicated than those for metal assemblies, and here the theorists had already demonstrated their ability to make accurate predictions.

The Gun

11.7 During the period under review relatively little new work had to be done on problems associated with the gun-assembly. Group T-2 remained in charge of this work, and prepared final calculations of the expected efficiency, including the predetonation probability. In the latter calculations

use was made of the integral experimental data obtained by Group R-1 from the gun model experiment (12.24).

The Implosion

11.8 By the beginning of the period discussed in this chapter, most of the calculations relating to the ideal implosion (starting with a converging symmetrical shock-wave at the outer edge of the tamper) had been completed, and it was possible to say that this part of the subject was almost completely understood. Implosion studies continued to be primarily the work of Group T-1.

11.14 The paragraphs above give a qualitative account of how the background was prepared, within the theoretical division, for the "freeze" of design which occurred in February, 1945.

DOE b(3)

DELETED DELETED DELETED

11.15 These decisions, made only five months before the Trinity test, set several new problems for the Theoretical Division. The first of these was to determine the effect of temperature on the course of the implosion.

DOE b(3)

DELETED DELETED DELETED The second was the question of proving the stability of convergent shock wave. Since it would be very difficult to get experimental information on the irregularities produced inside a solid core, it would be necessary to rely entirely on indirect evidence and on theory. The third theoretical problem of major importance was to provide specifications and to help design a modulated neutron initiator.

11.16 On the first of these problems, the effect of shock-heating on the course of the implosion, calculation of equations of state for DELETED DOE b(3) uranium were completed by April, and new IBM calculations of the DELETED DOE b(3) implosion thereafter included the effect of temperature. As a result efficiencies were decreased by a small amount, but less than had been anticipated.

11.17 On the question of stability of shocks, it was finally proven that plane shocks were stable, and the decay-rate of irregularities was found. In the absence of a complete theory for convergent shocks, it was nevertheless

possible to make rough estimates of the effects of instability

DOE b(3)

DELETED DELETED DELETED

11.18 In the design of the initiator, specifications were provided as to the initial neutron intensity required from the sudden mixing of polonium and beryllium. By April 1945 the design for the initiator had been frozen, the so-called urchin design (15.45).

DOE b(3)

DELETED DELETED DELETED DELETED

11.20 As the time of the Trinity test approached, the main effort of Group T-1 went into an attempt to explain certain discrepancies between the experimental data obtained from implosion studies in G Division and the results of the latest and most comprehensive IBM calculations. Densities measured by the betatron and RaLa methods were somewhat lower than the theoretical values. Measured shock velocities were also lower than theoretical values. Material velocities measured by the electric pin method were in agreement with theory, while those measured by the magnetic method were lower than predicted. A thorough canvassing of all the assumptions used in calculation, and examination of possible experimental errors, led finally to the conclusion that the theoretical calculations should be revised downward somewhat, but not by an

amount sufficient to alter the expected performance of the weapon very significantly.

Efficiency

11.21 During the period discussed in the present chapter the study of efficiencies, like that of other theoretical problems, moved from exploratory analysis intended to insure an essentially complete understanding of bomb physics, to final calculations of weapon design and performance, by the most reliable methods known. Efficiency calculations, in particular, carried the full responsibility of assuring the Laboratory that it was working toward an effective weapon, and of predicting as accurately as could be the efficiency of the bomb finally developed. In the nature of the case there could be no experimental verification of efficiency theory as a whole until the first test.

11.22 Several undertakings begun in the previous period were carried over and completed in the present period. The first of these was to examine carefully the effect of mixing between core and tamper, expected because of the Taylor instability at the interface.

DOE b(3)

DELETED DELETED DELETED

11.23 Another type of calculation considerably improved upon was the prediction of the initial multiplication rate for supercritical assemblies. Allowance for several groups of neutron velocities, in particular, introduced a transient time-dependence of this rate in the initial stages of multiplication. The comparison of this theory with experiments of Groups R-1 and G-1 was not satisfactory and required some re-examination of theory and experiments before good agreement was reached.

11.24 During this period, also, the qualitative understanding of the effect of radiation on the course of the explosion was brought to completion;

but reliable quantitative calculations remained impossible. Just before the Trinity test, therefore, the final efficiency prediction ignored this effect which, it was understood, might be responsible for a very much higher efficiency than that predicted.

11.25 As late as May, 1945, considerable worry was occasioned by the predetonation problem connected with the implosion assembly.

DOE b(3)

DELETED

DELETED

DELETED

DELETED

11.26 Final efficiency calculations, published in the Theoretical Division Progress Report for June (LAMS 267), gave a prediction that the yield at the Trinity test would lie between 5,000 and 13,000 tons of TNT. The actual yield of the Trinity explosion was certainly in excess of this upper limit. One quite successful measurement made during the test was the initial multiplication rate of the bomb as it exploded. Using this value and omitting some pessimistic assumptions made in arriving at the yield range quoted above, recalculation gave a value near 17,000 tons. Both because of the uncertainties in measuring the yield and also because of the large theoretical uncertainty introduced by ignoring the effects of radiation, the close agreement between this figure and the "official" yield of 17,000 tons conceals several unsolved

problems. The first of these is the effect of radiation. The second is the proportion of the energy released converted into blast energy. Uncertainty about the latter relations makes it necessary to distinguish between the "nuclear" efficiency (fission energy released) and the "blast" efficiency, derived from the measurement of the blast wave. In view of the complexity of the efficiency problem and the unknown factors entering into it, the correspondence between theoretical and measured values was remarkably good.

11.27 There was somewhat less close agreement between the very successful result of the Trinity test and the subjective anticipations of many members of the Laboratory, who had by one argument or another prepared themselves against disappointing results. Shortly after the Trinity test, therefore, there was some discussion of possible unanticipated effects that might have accounted for the unexpectedly high yield. DOE b(3)

Damage

11.28 Much more extensive investigation of the behavior and effects of a nuclear explosion were made during this period than had been possible before, tracing the history of the process from the initial expansion of the active material and tamper through the final stages. These investigations included the formation of the shock-wave in air, the radiation history of the early

stages of the explosion, the formation of the "ball of fire", the attenuation of the blast wave in air at greater distances, and the effects of blast and radiations on human beings and structures. Much of this information was of importance in making plans for the Trinity test. It was essential to know also the probable fate of plutonium and fission products in the ball of fire and the smoke cloud ascending out of it. These calculations, plus calculations of blast and radiation, were essential in planning experiments and observations at Trinity, and in planning for the protection of personnel. Theoretical studies of damage to structures and to personnel were of course made in anticipation of combat use. Extensive use in this connection was made of British data on damage to various kinds of structures caused by high explosive bombs. General responsibility for this work was given to Group T-7, with the advice and assistance of W. J. Penney.

Experiments

11.29 As in the earlier period reported (Ch. V), the consulting services of the Theoretical Division continued to occupy a considerable part of its time. Some of the more important lines of relationship have been discussed under the previous sections. Among the large number of neutron experiments on which the Division gave advice or performed computations may be mentioned the Gun Model experiment of Group R-1, the scattering experiments of R-3, the integral tamper experiments of R-1 and R-3, the multiplication experiments of R-1. For the Weapon Physics Division the theorists assisted with problems such as the design of RaLa experiments, the theory and analysis of magnetic pick-up data, and the focussing of x-rays for the x-ray method. Assistance was given, as before, in the design of various counters and detectors, and in calculating their efficiencies.

11.30 The most varied assistance was given to the operating groups engaged in the conduct of the Trinity experiment, all phases of which were under surveillance by the Theoretical Division which, as mentioned above, was responsible for preparing adequate order-of-magnitude calculations of the effects to be expected, and also for being sure that, in terms of these calculations, the experimental program was properly planned and coordinated.

11.31 In this place credit must be given to the computing Group, T-5, for its essential services in obtaining numerical solutions, required in most theoretical investigations.

Chapter XIII

F DIVISION

Introduction

13.1 As part of the administrative reorganization of the Laboratory, F Division was formed in September 1944, shortly after Fermi's arrival from Chicago. As Associate Director Fermi was given general responsibility for the theoretical and nuclear physics research of the Laboratory. As Division Leader of F Division he was given the directive to investigate potentially fruitful lines of development not included under the main program of the Laboratory. This responsibility included the Super in its theoretical and experimental aspects, and means of fission bomb assembly alternative to the gun and the implosion. Because of Fermi's previous association with pile development, the Water Boiler Group was also placed in this division. The last group in the division was added in February 1945, to do experimental work with the high power water boiler as a neutron source, and to prepare for the measurement of fission fragments at the Trinity test. The work of F Division in the Trinity test is reported in Chapter XVIII.

13.2 The group organization was as follows:

F-1.	The "Super" and General Theory	E. Teller
F-2.	The Water Boiler	L. D. P. King
F-3.	"Super" Experimentation	E. Bretscher
F-4.	Fission Studies	H. L. Anderson

The Super

13.3 During June of 1944 Teller's group had been separated from the Theoretical Physics Division and placed in an independent position, reporting to the Director. This separation was a recognition of the exploratory

character of this group's work as contrasted with that of the Theoretical Division generally, which had primarily responsibility for obtaining design data for fission bombs. Again in August 1944 Teller's group became the theoretical branch of the new F Division, created under Fermi.

13.4 Theoretical work on the Super from this time was without essential surprises. The analysis of the thermonuclear reaction became more quantitative and concrete. Increasing attention was given to the theory of detonation-mechanisms. Work reached its highest intensity in the spring of 1945 and continued for several months after the end of the war and the period covered by this report.

13.5 The detailed chronology and connections of these developments will not be traced here. There will be, rather, a qualitative account of the processes fundamental to the operation of a thermonuclear bomb, as finally understood. These processes are, in summary: the release of nuclear energy in high-temperature collisions, the transfer of energy from product particles to the medium, the loss of energy by radiation, the loss of energy because of the presence of low temperature radiation, the loss of energy through thermal conduction.

RELEASE OF ENERGY IN HIGH TEMPERATURE COLLISIONS

13.6 New measurements of the reactivity of deuterium with deuterons and tritons having the low energies of thermal motion were performed by Bretscher's group. (13.38). The new D-D data agreed with previous theoretical extrapolations from the old, high energy data. The low energy T-D reactions, however, turned out to have a considerably higher reactivity than even that anticipated from old measurements.

DELETED DELETED DELETED

13.7 The theoretical investigation showed that a steep rise in the rate of energy evolution can be expected with a rise in temperature.

DOE b(3)

DELETED DELETED

DELETED DELETED

TRANSFER OF ENERGY FROM PRODUCT PARTICLES TO THE MEDIUM

13.8 The nuclear energy released in the reaction of a deuteron or triton with a deuteron is transferred into the kinetic energy of the product-particles. This energy must, in turn, be used to heat the deuteron medium to produce more reactions. The product-particles transfer their energy through collisions. In general the energy is "deposited" in the medium through a chain of collisions, during which the product-particles disperse themselves. Because of this dispersion the volume to be initially heated must be large enough to catch most of the energy deposits; otherwise the product-particles will escape from the system with too large a part of their energy, and the reaction will fail to be self-propagating.

DOE b (3)

DELETED DELETED

DELETED DELETED

DOE b(3)

DELETED DELETED DELETED

LOSS OF ENERGY BY RADIATION

13.9 The mechanism of radiation-loss has already been described. Since the loss rate at low temperatures exceeds the production rate but rises much less rapidly with temperature, there is a minimum temperature, called the "ideal ignition temperature", at which the energy evolution reaches equality with the Bremsstrahlung loss rate. The qualification "ideal" refers to the fact that only radiation losses are so far taken into account, and not, for instance, the losses accounted for by the escape of product particles from the system with part of their energy.

DAMAGE

13.21 No account of the Super development at Los Alamos can be complete without some account of estimates of damage. It must be emphasized that these considerations are essentially qualitative. In fact with energies of the order contemplated, the effects of explosions begin to enter a new range, which may make necessary some account of meteorological and geological phenomena normally beyond human control. Under these circumstances accurate calculation is less important than a thorough canvassing of the possibilities.

The following account is highly tentative, both quantitatively and in degree of thoroughness.

13.22 The ten-million ton Super described above would not be the largest explosion seen on the Earth. Volcanic explosions and the collision of large meteorites such as the Arizona or Siberian have undoubtedly produced larger blast energies, perhaps a thousand or ten thousand times larger. On the other hand these explosions were very cool compared to a thermonuclear explosion, and correspondingly more familiar in their effects.

13.23 The blast effects from a ten-million-ton Super can be scaled up from the known damage at Hiroshima and Nagasaki. Taking the destroyed area from a ten-thousand-ton bomb to be ten square miles, the Super should produce equal blast destruction over a thousand-square-mile area. This would be more than enough to saturate the largest metropolitan areas.

13.24 More widespread ground damage would perhaps result from an explosion underground or underwater near a continental shelf. Since it is estimated that a severe earthquake produces energies of the same order as the Super, the surface effects might be comparable. To produce these effects would require ignition at a very great depth, of the order of several miles.

13.25 This bomb begins to reach the upper limit for blast destruction that is possible from detonation in air. Just as a fission bomb exploded in shallow water will have its radius of destruction in water limited by the depth at which it is exploded (14.21), so with a Super in the atmosphere. It "blows a hole" in the atmosphere, so that the maximum radius of destruction is comparable to the depth of the atmosphere.

13.26 Neutrons and gamma rays from the Super would not be a significant part of its damage; their intensity falls off more rapidly with

distance than the blast effects. Even at Hiroshima and Nagasaki they did not cause a large percentage of casualties. From a larger bomb their effects would be greater, but not proportionately greater.

13.27 The effects of visible radiation, on the other hand, fall off less rapidly than blast effects. This destruction can, in fact, be made directly proportional to the energy release. While blast damage can be increased a hundredfold, visible radiation damage can be increased a thousandfold. For the first purpose the bomb would be detonated about ten times higher than at Hiroshima and Nagasaki, for the second about thirty times higher. And the real point of the latter method is that there is no limit to the possibility of detonating larger bombs at higher altitudes. Thus a super which burned a ten-meter cube of deuterium at a height of three hundred miles would equal in effect a thousand "ordinary" supers detonated at ten-mile altitudes. In both cases the area of damage would be in the neighborhood of a million square miles. It should, of course, be emphasized that such a high altitude weapon is at the present time only a theoretical possibility.

13.28 It is difficult to estimate damage from visible radiation. In Hiroshima and Nagasaki the total effect was a composite of blast, gamma radiation and visible radiation. The last was sufficiently intense to ignite wooden structures over an area of a square mile or so. Casualties from visible radiation alone would be considerably smaller, because of the protecting effect of clothing and walls. Effects from a super would be comparable, and either more or less intense depending on the relative military importance of extensive versus intensive burning. The figures already given would correspond to an intensity about the same as that at Hiroshima and Nagasaki.

13.29 The most world-wide destruction could come from radioactive

poisons. It has been estimated that the detonation of 10,000 - 100,000 fission bombs would bring the radioactive content of the Earth's atmosphere to a dangerously high level. If a Super were designed with a U^{238} [DELETED] DOE b(3) catch its neutrons and add fission-energy to that of the thermonuclear reaction, it would require only in the neighborhood of 10 to 100 Supers of this type to produce an equivalent atmospheric radioactivity. Presumably Supers of this type would not be used in warfare for just this reason. Without the uranium [DELETED] DOE b(3) deuterium radioactive elements could be produced only by absorption; for example, carbon^{14} could be produced in the atmosphere; not, however, in dangerous amounts. Poisoning, moreover, would be obviated by detonation above the atmosphere, which is in any case the region in which the general destructive effects of the Super seem greatest.

13.34 Some time was spent on safety calculations for the K-25 diffusion plant, principally on estimations of critical assemblies of enriched uranium hexafluoride under various conditions and degrees of enrichment.

13.35 A topic of interest in connection with the Trinity test was the formation of chemical compounds in air by the nuclear explosion. Such compounds as oxides of nitrogen and ozone are poisonous, and the quantity produced had to be estimated. It was also anticipated that they would affect the radiation history of the explosion, which was to be examined spectrographically.

Deuterium and Tritium Reaction Cross Sections

13.36 It was stated above (13.6) that the low-energy cross section of the T-D reaction was found to be higher than extrapolation from high energy

data had indicated. This discovery, which considerably lowered the ignition temperature of T-D mixtures, was the result of work undertaken at the beginning of the period under review by Group F-3, the Super Experimentation Group.

DOE b(3)

DELETED DELETED DELETED

13.37 Since both the T-D and the D-D cross sections at low energies were known only by rather dubious extrapolation, it was planned to measure them simultaneously.

13.38 The first series of measurements was made with a small (50 kev) Cockcroft-Walton accelerator constructed for the purpose at Los Alamos. With this equipment experiments were carried out in the region from 15 to 50 kev. The quantity measured was the total number of disintegrations as a function of the bombarding energy, from which the reaction cross sections could be derived. In both cases the target used was made of heavy ice cooled with liquid nitrogen. The D-D reaction was produced by a deuterium ion beam, and the protons produced in the reaction measured. In the case of the T-D reaction the procedure was analogous, except that special precautions had to be taken to conserve the small amount of tritium available as an ion source. In this case the alpha particles from the reaction were counted.

13.39 The result of these measurements was that the extrapolated values of the D-D cross section were shown to be approximately correct. The tritium cross section, however, was very much larger than had been anticipated at energies of interest DELETED DELETED DOE b(3)

13.40 These measurements were later (after the end of the period under review) extended to the 100 kev region, using a larger accelerator constructed for the purpose.

A large amount of enriched uranium, surrounded by polythene, had been placed in a container to which water was being slowly admitted. The critical condition was reached sooner than expected, and before the water level could be sufficiently lowered the reaction became quite intense. No ill effects were felt by the men involved, although one lost a little of the hair on his head. The material was so radioactive for several days that experiments planned for those days had to be postponed.

15.11 Similar safety tests were made on models of the gun assembly. These tests were made because water immersion of the bomb might occur accidentally in transporting the bomb or in jettisoning it from aircraft. Immersion could also be thought of as the limiting case of wetting from other possible sources.

15.12 The number of tests made with U^{235} metal assemblies was much larger than those with Pu^{239}, since sufficient plutonium was available only rather late. The first critical assembly of the latter material, which was of a water solution of Pu^{239} with a beryllia tamper, was made in April 1945. By fabricating larger and larger spheres of plutonium and inserting these in a bomb mock-up, the critical mass in a bomb was determined.

DOE b(3)

DELETED DELETED DELETED

15.13 In April 1945 when G Division was given the definite responsibility of designing the pit assembly of the bomb, the "G Engineers", Morrison and Holloway, were taken for this work from the Critical Assemblies Group. The G Engineers worked with the design staffs of X and O Divisions in the final detailed design of the implosion bomb.

Implosion Studies: The X-Ray Method

15.15 The X-raying of small spherical charges was developed in the Ordnance Division and was in successful use in August 1944 (7.70). At this time the small scale work was placed in X Division, and the G Division X-ray Group was formed to extend this method of implosion study to larger scale. In addition to this development work the G Group continued a number of service activities, such as the servicing and improvement of the X-ray tubes for the X Division work. Other demands made upon them included the radiography of explosive charges for the RaLa Group. Radiographic examination of the final weapon tamper was also a problem for this group near the end of this period but the work was done with radioactive sources of gamma rays rather than with X-rays.

15.16 In the early part of the new program the chief objective in the development work was to adapt X-ray techniques to large scale implosions (up to

200 pounds of high explosives). It was proposed actually to follow the course of the implosion by detecting the incidence of the X-rays as a function of time, using a grid of small Geiger counters. These counters were to be either of one or three millimeters in diameter, and disposed in the form of a cross in the X-ray shadow of the object. The principal aims of the projected program were (1) reliable action of the counters and (2) reduction of the amount of scattered radiation that would be recorded. These objectives were pursued relentlessly, but because of the great technical difficulties involved, with little real success. The program was dropped in March 1945. It had become clear that, although the difficulties might not be insurmountable, there was not sufficient justification for retaining the highly trained personnel required for this work. At this time also it had become clear that essentially the same type of information was obtainable by repeated exposures with the betatron (15.26 ff).

15.17 Although the development of the counters and their electronic circuits and the reduction of the scattered radiation were uncertain of success in the new X-ray program, preparation of a field site where the technique could be tested was completed by early fall 1944. This site was called P Site. The protection required for X-ray equipment near exploding charges was designed so that it would be useful in other X-ray experiments as well. As a preparation for the final use of the X-ray and counter technique, the problems of using the magnetic method (15.20) in conjunction with the X-ray method were solved at P. Site. The first combined X-ray and magnetic record was obtained in late January 1945. The technique was directly applicable to the combination of betatron and magnetic records (15.29).

15.18 For the most part the great usefulness of P Site was in providing for small scale X-ray experiments with photographic plate exposure. DELETED

DOE

P Site, were under the direction of Tuck [DELETED] [DELETED] [DELETED]

DOE b(3)

15.19 As emphasis on lens design [DELETED] [DELETED] the flash X-ray photography was used in the study of the interaction jets formed at the intersection of detonation waves. These studies paralleled those of the X-ray section of the Implosion Studies Group X-1 (16.9 ff).

DOE b(3)

[DELETED] [DELETED] [DELETED]

From March on, therefore, the work of the X-ray Group at P Site was largely devoted to the study of various proposed initiator mechanisms.

DOE b(3)

[DELETED] [DELETED] [DELETED]

In April 1945 a second X-ray team was placed on the initiator problem. Altogether, a large amount of important experimental work on initiators was accomplished. The use of P Site for the initiator program branched out into various recovery experiments carried out there, and finally to the installation of the alpha counting experiment (15.44) there.

Implosion Studies: The Magnetic Method

15.20 By August 1944 the magnetic method had been established as a practical way of determining the velocity of the external metal surface of an imploding sphere (7.70). By integration the average compression could also be obtained. The development of the method was directed along three main lines: (1) the improvement of the instrumentation and adaption of the method to large charges with electric detonation; (2) cooperation with Bala, X-ray and betatron experiments to get coordinated records and (3) the development of new methods.

15.21 The first part of the program started with the construction of a

separate proving ground in the Pajarito Canyon (see Site Map). This was completed in December 1944. Meanwhile a great deal of work was done in the Laboratory in improving the circuits and developing shielding techniques. When the field work got under way it was found that the main problem was to protect the magnetic record against spurious signals caused by the electric detonators and by the static charges developed in the explosion. New results were obtained when it became possible to "purify" the magnetic records and interpret their details. It was found that several reflected shock waves from the metal core could be recognized. The intersection of detonation waves also produced reliable signals.

15.22 The magnetic techniques were adapted to larger charges, more detonation points, and finally to the electric detonation of lenses. The increase of surface velocity with number of detonation points was demonstrated in this way.

15.23 A unique property of the magnetic method was the fact that it was the only experimental method that could be applied to a full scale implosion assembly. The electric method (15.37ff) could be applied at full scale, but not to complete spheres. One of the chief objectives of the magnetic program was to prepare for the investigation of full scale shots. Unfortunately the method could not be used at Trinity because it was desirable to fire that shot with the same type of metal case as used with the bomb assembly, and this case made it impossible to obtain magnetic records.

15.24 As technical difficulties were surmounted the method was applied successfully at DELETED tamper diameters. At these scales the method was used alone as well as in coordination with the RaLa and Betatron methods. The timing results were particularly useful in these cooperative tests. As a method by itself its main value lay in following the dynamic sequence in the implosion and giving data as to the way this changes with increasing size of the implosion. DELETED DELETED DELETED

DOE b(3)

DOE b(3)

15.25 Although the magnetic method rapidly developed into a widely used research tool in essentially its original form, it was widely recognized that this method was limited by the fact that

Implosion Studies:: The Betatron

15.26 The use of the betatron as an instrument to study the implosion had been proposed earlier, but was not decided upon until the time of the discussions which led to the formation of G Division. For this work the 15 million volt betatron of the University of Illinois was obtained, after expert analysis of its capabilities for this work by its inventor, D. W. Kerst, and of the possible use of a vertical cloud chamber for recording by Neddermeyer. These analyses gave sufficient promise of success to justify undertaking the development of the method. Experimental work was begun in the early fall of 1944, on the performance (rise and burst times) of the betatron at Illinois and also on the refinement of shadow recording by means of flash photography of the cloud chamber.

15.27 Construction of the betatron site (K Site) was begun concurrently. As at the X-ray site, the test implosion was detonated between two closely spaced

bombproof buildings, one containing the high voltage gamma ray source, the other containing the cloud chamber and recording equipment. Equipment was protected from the blast by aluminum nose pieces over the exit and entry ports through which the radiation passed, and by shock-mounting all equipment which could be damaged by the shock wave. Construction and installation required until the first of 1945 for completion.

15.28 In the meantime the cloud chamber technique was improved by finding means for trapping the low energy tracks to obtain better definition of the image in the cloud chamber, and by an intricate and ingenious sequence circuit developed in the laboratory. This circuit had to correlate the firing of the explosive charge, the gamma ray burst, and the expansion and photographing of the cloud chamber.

15.29 By the time the first test shots had been fired [DELETED] [DELETED] [DELETED] the importance of results from the betatron had become crucial because of the likely abandonment of the counter X-ray method. The adaptation of the field installations, the electronic circuits and the cloud chamber to their special purposes proceeded so rapidly that by April 1945 a systematic study of compression under lens shots at [DELETED] scales was started. The results of the early work showed an unexpected irregularity, but nonetheless gave evidence of definite compression of the [DELETED] uranium core by an amount not very different from that predicted theoretically. By June, the spread of data had been reduced enough to provide valuable experimental information for the correction of the constants used in the theory of the bomb. Cooperative data provided by the magnetic method (15.20 ff) indicated that the spread in experimental results was possibly caused by variation in the behavior of the high explosive.

15.30 The betatron program was one of the few that maintained a single purpose and function from its inception to the production of final results. If

for this reason its history can be written briefly, the technical achievements and ultimate importance of this work are among the most impressive of the several such achievements at Los Alamos.

Implosion Studies: The RaLa Method

15.31 The RaLa program (7.74) resembles the betatron effort in that it was a single-purpose, more or less direct, adaptation of a known radiographic technique to the study of implosions. Both methods had to be adapted to microsecond time resolutions. For RaLa this meant the development of unprecedented performance with ionization chambers as well as unheard of sources of gamma radiation. As has been said elsewhere (17.52), the source of radioactivity was the radiobarium from fission products of the chain reacting pile. By the fall of 1944, the extraction of radiolanthanum had been put on a working basis. The production of sufficiently fast ionization chambers had also been achieved.

15.32 The RaLa firing program itself got under way in Bayo Canyon (see Site Map), October 14, 1944. Because of the lack of knowledge as to how serious the contamination would be after imploding a source which was the equivalent of many hundred grams of radium, the permanent installations were kept at a minimum for these first trials. Sealed army tanks were used as observation stations. The contamination danger appeared so conveniently small, however, that permanent bomb proofs were subsequently installed (November 1944).

15.33 The early shots were fired by multipoint, primacord systems and the results were correspondingly erratic.

DOE b(3)

DELETED DELETED DELETED

DOE b(3) 1

DELETED DELETED DELETED

15.34 In February electric detonators were put into use and the quality of RaLa results immediately improved. In the course of the spring further refinements were made in the ionization chambers. Protection was provided against spurious signals. Provision was made for obtaining simultaneous magnetic records. As a result the significance of the results obtained was so improved that the RaLa method became the most important single experiment affecting the final design of the bomb. The principal advantage of the method was that analysis of the data gave an average of the compression as a function of time. This threw light on two of the most critical attributes of the system, namely, the duration and magnitude of maximum compression. A disadvantage of the method was that uranium had to be replaced by cadmium and full scale shots could not be made. Since uranium had too much gamma ray absorption, an IBM calculation had to be made for the RaLa model as well as the bomb model. If the RaLa calculation agreed with the experiment then it was assumed that the calculation for the actual bomb was probably also correct.

15.35 A second RaLa site was started in March 1945 in order to utilize the ever increasing amounts of activity available. The first high quality lenses produced were allocated to this work, beginning in April, so as to approach final design as rapidly as possible.

15.36 The RaLa program was relatively straightforward, but its success was possible only because of unsparing pains in the construction and testing of equipment, under almost assembly-line conditions of operation. Each shot involved the destruction of ionization chambers and electronic equipment that could not be removed from the neighborhood of the shot. Each new set of equipment had to be completely checked to be sure of proper operation on the single occasion that counted

Implosion Studies: The Electric Method

15.37 The principal technique of the electric method of investigating the implosion was that of recording electronically the electrical contacts formed

between the imploding sphere and prearranged wires. This is a well-established method of investigation but, as always in adapting old methods to implosion work, it was necessary to sharpen the time resolution and meet rather more serious interference with the circuits on the part of the explosive than had previously been encountered.

15.38 The development of the electric method was undertaken in August 1944. Although many possible applications of electronic circuits suggested themselves, the first effort was to make oscillographic recordings of the position of a plate as a function of time, when the plate was accelerated by a high explosive charge. This was done by merely spacing small pins at intervals differing by about a millimeter from the surface to be accelerated. The first successful results were obtained in early October 1944. The technique was then rapidly developed and refined, so that by the early part of 1945 quantitative data on the acceleration of plates was being obtained. The method was then adapted to the more severe implosion of partial spheres, and finally used on lens systems in which only one lens was omitted. Information was obtained on velocities of material at various depths in the core, and on shock-wave velocities. This information was particularly valuable in supplying the Theoretical Division with direct, quantitative data on which to test its conclusions and base its predictions for the implosion bomb.

15.39 Variations of the technique described above were studied but not developed as fully as the contact method. These included the condenser microphone and resistance wire methods. The use of tourmaline crystals for timing signals, as well as for possible pressure recording was pursued by the Initiator Group. In addition to the information, of general theoretical interest, on the properties of metals under compression, these methods were useful in many particular studies. Thus the Initiator Group was able to determine the pressure distribution in a detonation wave, and the Electric Method Group measured transit times relative to detonation times, uniformity of lens operation and the location and velocities of

spalls and jets. They also measured many velocities of interest in connection with initiator design, and the velocity of shock-operated jets formed in the thin crack between tamper halves.

15.40 Aside from its general usefulness for many research purposes of G Division, the Electric Method was--apart from the magnetic method--the only one which could be applied at very large scale. By June 1945, the technique was being applied regularly at large scale and to almost complete spheres of lens charges.

Initiators

15.41 The Initiator Group differed from those discussed above in that it was primarily concerned with the development of a component of the bomb rather than with a particular research method.

DOE b(3)

DELETED DELETED DELETED

DELETED DELETED DELETED

DOE b(2)

DELETED DELETED DELETED

15.42 A proving ground was built in Sandia Canyon (see map) for this work. The nature of proof was not predetermined, however, and in any case could not be complete, because the performance requirements could be measured only by operation in the bomb itself. Many leads were followed, accordingly, in the attemp to simulate actual conditions as closely as possible and to learn as much as possible about the mechanisms that were supposed to make the various designs work.

15.43 The initiator program involved a great deal more than the attention of the Initiator Group. A large part of the problem was the procurement and radiochemical preparation of polonium. (17.38 ff) There was considerable theoretic investigation of proposed initiator mechanisms, and a large amount of experimental corroboration was produced by the X-ray, flash photography and electric methods. The function of the Initiator Group was to coordinate these researches with its own and with trends in design.

15.44 By February 1945 it was pretty well decided that the initiator should be of an (α,n) type using polonium and beryllium. Many designs were invented, and the work of selecting promising ones and testing them was started. All designs worked by some mechanism for mixing polonium and beryllium, previously kept separated by some α-absorbing material such as gold, under the impact of the incoming shock-wave. At this time the possibility of complete recovery of imploded spheres was discovered. The recovery of units with and without polonium in them formed an important part of the early work. Although the results thus obtained built up confidence in the feasibility of initiators, this work was superseded by studies of specific mechanisms.

15.45 The deadline for a decision on the feasibility of an initiator was met, with a favorable report, on May 1, 1945. At that time the decision was made to concentrate on the "urchin" design for production of a service unit.

DOE (3)

DELETED DELETED DELETED

DOE b(3)

DELETED DELETED DELETED

15.46 In the course of the month after May 1 the acceptance specifications and fabrication procedures were established and the first service unit was finished by the radiochemists early in June. (17.45) (Appendix 7, No.34)

15.47 The Initiator Group set up handling procedures in cooperation with the G Engineers and the Radiochemists for production, surveillance and recording the history of each unit. This plan had just been put in operation by the end of the wa

Electric Detonators

15.48 The need for a high degree of simultaneity in the multipoint detonation of the implosion had been realized from the beginning, as had the potential usefulness for this purpose of electric detonators. The early development of primacord branching systems, the investigation of timing errors associated with them, and the experimental and theoretical discovery of the crucial importance of such errors, is reviewed in 7.76 and 16.15 ff. Electric detonators were already under development by the beginning of the period reviewed, and during August 1944 this work was transferred to the new G Division.

15.49 The degree of perfection desired was, of course, not built into the commercial electric detonators, and the problem of simultaneously firing many such units had not been faced. This required the development of an adequate high voltage power supply and of a simultaneous switching device. The high voltage supply could be made from commercial units, and was simply a bank of high voltage condensers. The switch problem, acute at first, was met by straightforward developments which led to several designs adequate for experimental purposes. The switch finally developed for weapon use and the particular DELETED detonators

DOE b(3)

used, were proved in X Division (16.58) But with a firing circuit adequate for experimental purposes it soon became apparent that there was a serious lack of simultaneity and source of failure in the detonators themselves.

15.50 Detonators of two types were studied, the bridge wire and spark gap types. Impetus for the study of spark gap detonators with lead azide came from England in the summer of 1944, where detonators of this sort were being fired with timing errors reduced to microseconds. The reduction of errors came from the use of powerful high voltage spark discharges. The use of similar high voltage energy sources with commercial bridge-wire detonators at Los Alamos also showed a comparable reduction of timing errors. It was wrongly assumed that even with powerful electric discharges only primary explosives -- i.e. those normally used for detonation of less sensitive explosives -- could be used. A contract was arranged with the Hercules Powder Company for the production of several types of experimental detonators, mostly loaded with lead azide.

15.51 Because of delays in manufacture, only a few batches of these detonators were received. In the meantime facilities for rapid loading of experimental detonators were developed at Los Alamos, and this local supply became the primary one.

15.52 The main path of detonator development was determined by another discovery at Los Alamos in the late summer of 1944. This was the fact that, with the high energies necessary to detonate primary explosives with small timing errors, PETN could also be detonated with comparable timing errors, and could not be detonated at all with lower energies. This was of great importance from the standpoint of safety, particularly safety in battle use, because it reduced the possibility of accidental detonation from such sources as accumulated static charges or leakage from low voltage energy sources in the bomb. The use of PETN detonators made it possible, among other things, to eliminate the use of "safety gates", mechanical separators between the detonator and the high explosive, which would

have been a most troublesome design problem had their use been necessary.

15.53 Many factors were found to affect the timing or the energy threshold of the PETN detonators: Mechanical factors, such as the length, diamete and composition of the bridge wire, its location in the detonator cavity and the shape of this cavity, electrical factors, such as the voltage and capacity of the energy source, impedance in the circuit, variations in resistance between detonato connected in parallel; the explosive, its density, particle size and crystal form. These latter factors were so important that careful control of the preparation and loading of detonators was necessary.

15.54 The criterion for acceptance was of course a small maximum time spread and percentage of failures. Tests were made by oscillographic methods and later by photographic observation, using the rotating mirror camera.

15.55 In the spring of 1945 the Detonator Group was burdened with the supervision of the preparation of thousands of detonators for field work in the implosion program. By the end of May the specifications for the combat service units had been completed, and responsibility for putting the units into service was taken by Group X-7 (16.58-9).

Photography

15.56 The Photographic and Optics Group, which before August 1944 had been a part of the Instrumentation Group of the Ordnance Division, was responsible in G Division for the development of optical instruments and for the operation of technical photographic facilities. As such it was partly a service group and partly an experimental group. It prepared photographic and spectrographic equipment for the Trinity test. Before that it had played a substantial part in the Wendover drop tests.

15.57 Besides procurement of photographic equipment and maintenance of a photographic stockroom, the Photographic Group designed and built cathode ray oscilloscope cameras, armored still cameras for various high explosives test sites,

an armored stereoscopic camera for the flash photography of imploding hemispheres (16.12) and a cloud chamber stereoscopic system for the betatron cloud chamber (15.28). The group built boresights and a photo velocity system for the 20 millimeter gun. It designed and developed the rotating prism and rotating mirror cameras(15.54). As with electronic, so with photographic recording of data, the laboratory was able to reach a high level of perfection in accurate high speed work. Much of this work stands to the credit of the Photographic Group.

Electronics

15.58 Early in September 1944, the Electronics Group was greatly expanded because of the very heavy demands placed on it by the Laboratory. At this time many types of equipment were in production. Among the standard items made were scalers, power supplies, discriminators and two types of amplifiers with rise times of 0.1 and 0.5 microseconds. Many new pieces of equipment were designed and built. A scaler with a resolving time of 0.5 microseconds per stage, amplifiers with less than 0.05 microseconds rise time, a ten-channel pulse height analyzer, and a ten-channel time analyzer were constructed. The group built most of the electronic equipment used on the betatron and much auxiliary equipment for the cyclotron, van de Graaffs and D-D sources. It designed and built new sweep circuits, delay circuits calibrating circuits and a host of other circuits needed by a laboratory as large and diversified as Los Alamos had become. If the above gives some indication of the variety of work carried out by the Electronics Group, its magnitude is indicated by the fact that the membership of the group averaged in the neighborhood of fifty. These ranged from wire men to designers of new equipment. The number of major construction items ranges over a thousand, and the number of service and repair items far beyond this figure, for the period covered.

15.59 The services of this group are not reflected directly in a single part of the weapons finally developed at Los Alamos and for this reason are likely to be slighted. But it is safe to say that without its services many of the expe

ments of G Division and the Laboratory would not have been done as well, they would have required more time, and the completion of the bomb itself would have been delayed.

Results of Trinity Experiments

13.29 To give some notion of the number and scope of the experiments done in connection with the Trinity test, the following summary is included. (See chart of location of Trinity experiments in appendix). There were six chief groups of experiments: 1. Implosion; 2. Energy release by nuclear measurements; 3. Damage, blast and shock; 4. General phenomena; 5. Radiation measurements and 6. Meteorology.

1. Implosion experiments included:
   a. Detonator asimultaneity measured with detonation wave-operated switches and fast scopes. These records were fogged by gamma rays.
   b. Shock wave transmission time measured by recording on a fast scope the interval from the firing of the detonators to the nuclear explosion. This experiment gave a result [DELETED] in exact accord with predictions.
   c. The multiplication factor (a) measurement was done by three methods - with electron multiplier chambers and a time expander; by the two chamber method; and with a single coaxial chamber, coaxial transformers and a direct deflection high speed oscillograph. [DELETED] [DELETED] [DELETED]

DOE b(3)

DOE b(3)

2. The calculation of energy release by nuclear measurements included:
   a. Delayed gamma rays measured by ionization chambers, multiple amplifiers, and Heiland recorders from both ground and balloon sites.

b. Delayed neutron measurements done in three ways - by the use of a cellophane catcher and U^{235} plates both on the ground and airborne, by the use of gold foil detectors to give an integrated flux, and by the use of sulphur threshold detectors. For the cellophane catcher method a record was obtained from the 600 meter station which showed an energy release consistent with the H. Anderson figure (c. below). With the gold foil method the number of neutrons per square centimeter per unit logarithmic energy interval was measured at 7 stations ranging from 300 to 1000 meters from the explosion. Of the sulphur threshold detectors only 2 of the 8 units used were recovered and these gave the neutron flux for energies of 3 Mev at 200 meters.

c. The conversion of plutonium to fission products, measured by determining the ratio of fission products to Pu, gave a result DELETED DELETED equivalent to 18,600 tons of TNT. An attempt to collect fission products and plutonium on filters from planes at high altitude from the dust of the shot after it circled the world gave no results, although later some indications were obtained after the Hiroshima explosion by this method.

DOE b(3)

3. Damage, blast and shock experiments were divided into three groups: a. Blast, b. Earth shock and c. Ignition of structural materials.

a. Blast measurements included:

(1) Quartz piezo gauges - these gave no records since the traces were thrown off scale by radiation effects.

(2) Condenser gauges of the California Institute of Technology type were located from 3-19 [illegible] but no

records were obtained because the shot had to be fired when the planes were out of position.

(3) The excess velocity of the shock wave in relation to sound velocity was measured with a moving coil loudspeaker pick-up, by the optical method with blast-operated switches and torpex flash bombs and by the Schlieren method. By the moving coil loudspeaker method the velocity of sound was obtained for a small charge and then the excess velocity for the bomb; this measurement gave a yield of 10,000 tons and proved to be one of the most successful blast measuring methods.

(4) Peak pressure measurements were done with spring loaded piston gauges at an intermediate pressure range of from 2.5 pounds to 10 pounds per square inch, with the same kind of gauges above ground and in slit trenches at a pressure range of from 20 to 150 pounds per square inch, with crusher type gauges and with aluminum diaphragm "box" gauges at a range of from 1 to 6 pounds. The first of these methods gave blast pressure values which were low compared to all other methods, the crusher type gauges gave the highest pressure range and the "box" gauges gave a TNT equivalent to 9900 ± 1000 tons. This last method was found to be inexpensive and reliable.

(5) Remote pressure barograph recorders gave results consistent with 10,000 tons. These were necessary for legal reasons.

(6) Impulse gauges - mechanically recording piston liquid [illegible] orifice gauges - also gave results consistent with [illegible] tons.

(7) Mass velocity measurements were made by viewing with Fastax cameras suspended primacord and magnesium flash powder.

(8) Shock wave expansion measurements were made with Fastax cameras at 900 yard stations and gave a total yield of 19,000 tons.

b. Earth shock measurements included:

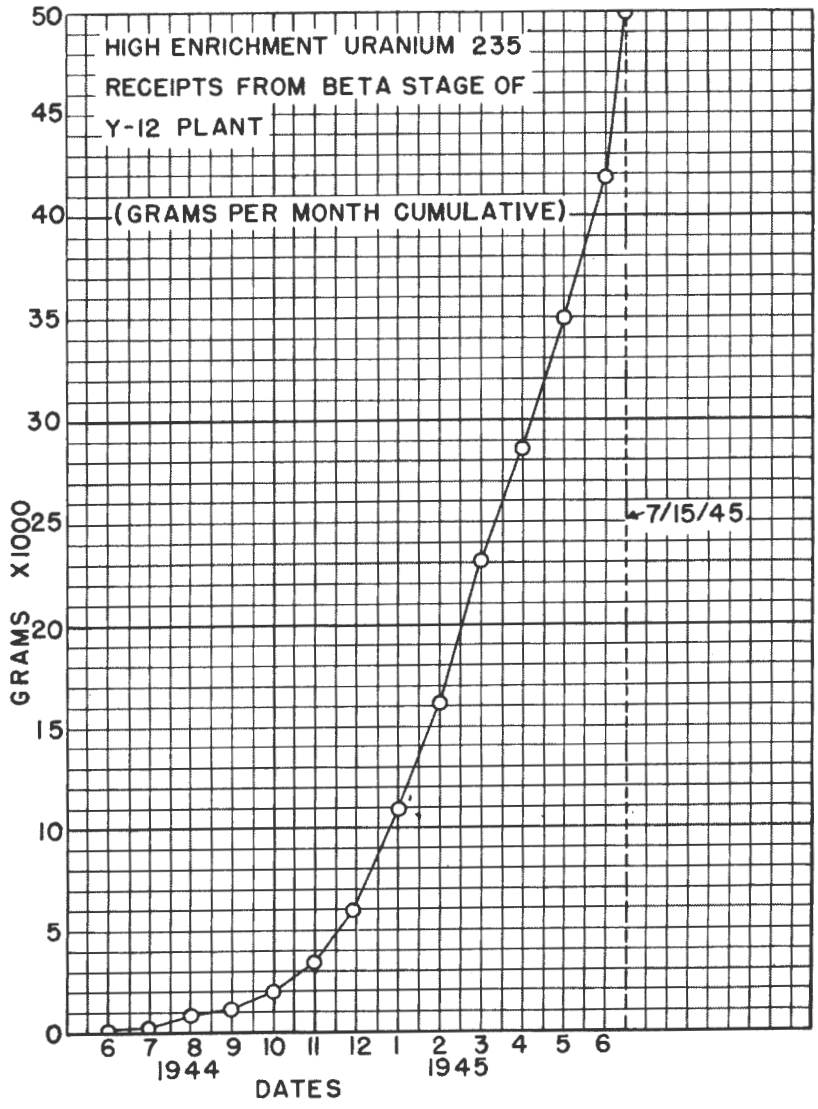
(1) Geophone measurements with velocity-type moving coil strong motion geophones gave 7000 tons after extrapolation from a small charge and 100 ton data.

(2) Seismograph measurements done with Leet 3-component strong motion displacement seismographs gave results of approximately 15,000 tons. These were necessary for legal reasons.

(3) Permanent earth displacement measurements using steel stakes for level and vertical displacements gave results of 10,000 ± 5000 tons.

(4) Remote seismographic observations at Tucson, El Paso and Denver showed no effect at these distances.

c. The ignition of structural materials was observed using roofing materials, wood and excelsior on stakes. Observations showed that the risk of fire produced by radiant energy is small for distances greater than 3200 feet. The risk of fire from direct radiation was likely to be much less than the risk of fire from stoves etc. at the time of the explosion. These conclusions were confirmed at Hiroshima and Nagasaki.



4. The study of general phenomena consisted chiefly of photographic studies of the ball of fire and the column of blast cloud effects. This group of

Cumulative total of Pu 239 receipts from Clinton and from Hanford. Clinton production very small, increasing slowly until it ended in February 1945. Hanford startup was in September 1944 and first material was received from there in February 1945.

Information was obtained from records of receipts in Director's Office, now filed with the Quantity Control Section of the Chemistry and Metallurgy Division.

(α,n) reaction

Any nuclear reaction in which an alpha particle (helium nucleus) is absorbed by a nucleus, with subsequent emission of a neutron.

Autocatalytic Assembly

Any method of assembling super-critical amounts of nuclear explosive, in which the initial stages of the explosion are made to assist the further assembly of the explosive, e.g., by expulsion or compression of neutron absorbers placed in the active material.

Baratol

A castable explosive mixture of barium nitrate and TNT.

Baronal

A castable explosive mixture of barium nitrate, TNT and aluminum.

Betatron

Induction electron accelerator for generating electron beams of very great energies.

Branching ratio

The ratio of the capture cross-section to the fission cross section.

Cockcroft-Walton Accelerator

An accelerator using voltage multiplication of the rectified output of a high voltage transformer to obtain a high potential.

Composition B

A castable explosive mixture containing RDX, TNT, and wax in the proportion 60/40/1.

Critical Mass

That amount of fissionable material which, under the particular conditions, will produce fission neutrons at a rate just equal to the rate at which they are lost by absorption (without fission) or diffusion out of the mass.

Tamped Critical Mass

The critical mass when the active material is surrounded by a tamper.

Critical Radius

The radius of a spherical arrangement of fissionable material equal to one critical mass under existing conditions.

Cross-Section

A quantitative measure of the probability per particle of the occurrence of a given nuclear reaction. It is defined as the number of nuclear reactions of a given type that occur, divided by the number of target nuclei per square centimeter and by the number of incident particles.

Absorption Cross-Section

The cross-section for the absorption of a neutron by a given nucleus.

Capture Cross-Section

The cross-section for the (n,γ) reaction, in which a neutron is absorbed by a nucleus, with subsequent emission of gamma radiation.

Fission Cross-Section

The cross-section for the absorption of a neutron, followed by fission.

Scattering Cross-Section

The cross-section for the scattering of a neutron by the nuclei of some target material. Since scattering is a quantitative matter, the definition is incomplete. The differential scattering cross-section is the cross-section for scattering at an angle between θ and $\theta + d\theta$. The transport cross-section is an average or integral scattering cross-section, so defined as to give the average scattering in the forward direction:

SECRET RD

$$\sigma_T = 2\pi \int_0^{\pi} (1 - \sin\theta)\, \sigma_s(\theta) \sin\theta \, d\theta$$

where $\sigma_s(\theta)$ is the differential scattering cross-section defined above.

Cyclotron

Magnetic resonance accelerator, used in investigating atomic structures.

D(d,n) reaction

The nuclear reaction produced by bombarding deuterons with deuterons, producing high energy neutrons.

D-D Source

The above reaction used as a source of high energy neutrons. At Los Alamos, the Cockcroft-Walton accelerator was principally used for this purpose.

Deuterium

Heavy hydrogen, D_2 or H_2^2, the hydrogen isotope of mass two.

Deuteron

A nucleus of deuterium or heavy hydrogen.

Electron Volt

An electron volt is the energy acquired by an electron falling through a potential of one volt. One electron volt is about 1.6×10^{-12} ergs. In thermodynamic units, one electron volt corresponds to a temperature of about 12,000 degrees absolute. Thus a fortieth of a volt per particle corresponds to "room temperature". Energies of this order are called "thermal". One million electron volts corresponded to a temperature of 1.2×10^{10} degrees absolute.

Fission Spectrum

The spectrum, or energy-distribution, of neutrons emitted in the fission process.

SECRET RD

Inelastic Scattering

The scattering of neutrons in which energy is lost to excitation of target nuclei.

Li(p,n) reaction

The nuclear reaction in which neutrons are produced by bombardment of lithium by protons.

Neutron Number

The number of neutrons emitted per fission. This number is statistically variable; the expression refers therefore to the average number per fission.

(n,γ) reaction

A nuclear reaction in which a neutron is captured by a nucleus, with subsequent emission of gamma radiation.

PETN

Pentaerythritol tetranitrate.

RDX

Cyclotrimethylenetrinitramine.

Thermo-Nuclear reaction

A mass nuclear reaction induced by thermal agitation of the reactant nuclei. The reaction is self-sustaining if the energy release is sufficient to counter balance the energy losses that may be involved.

Tamper

A neutron reflector placed around a mass of fissionable material to decrease the neutron loss rate.

Taylor Instability

A hydrodynamical principle which states that when a light material pushes against a heavy one, the interface between them is unstable, and that when a heavy material pushes against a light one, the interface is stable.

Tritium

The hydrogen isotope of mass three. This isotope was discovered in the Cavendish Laboratory by Oliphant in 1934. It was there produced by deuterium-deuterium bombardment. Tritium is a radioactive gas with a half-life of about twenty years, and therefore does not occur in nature.

Triton

A nucleus of tritium.

Thermal Neutrons

Neutrons of thermal energy - see Electron Volt.

T-D reaction

The nuclear reaction of tritons with deuterons.

Torpex

A castable explosive mixture of RDX, TNT and aluminum.

Van de Graaff Generator

An accelerator using the electrostatic charge collected on a mechanically driven belt to obtain a high potential.

FOREWORD

This introductory volume presents a general discussion of the main features of the Gaseous Diffusion (K-25) Project. The purpose of the Project, authorization, theoretical foundations, preliminary planning, safety and security aspects, costs, and administrative organization are treated, and a brief overall description is given, with an indication of scope and magnitude, as well as a statement of problems posed by the decision to utilize the method of gaseous diffusion. The various aspects, as listed below, are dealt with briefly. In general, when greater detail is desired, reference should be made to succeeding volumes of Book II as follows:

Volume 2 - Research
Volume 3 - Design
Volume 4 - Construction
Volume 5 - Operation

Activities described in Volume 1 extend from the earliest OSRD contracts, negotiated in July 1941, for the study of the diffusion process, to 31 December 1946, at which time all basic phases of the K-25 program of research, design, and construction had been effectively completed, the gaseous diffusion plant existed as an operating entity, and administrative responsibility passed from the Manhattan District to the United States Atomic Energy Commission. The term, "K-25 Project" is used throughout in the broad sense, and is synonymous with "Gaseous Diffusion Project". The K-27 plant addition is viewed as a supplementary portion of the K-25 process plant. No new basic principles are involved in K-27, and its discussion is interlooked with that of the original phases of the Project throughout the course of Book II.

SUMMARY

1. Introduction. - The goal of the Gaseous Diffusion (K-25) Project was the large scale, multi-stage separation of Uranium-235 from the more abundant non-fissionable Uranium-238 by utilization of the principle of molecular effusion. The complete novelty, both of the manufacturing process, and of the process material, made necessary a major program of fundamental research, development, engineering, design, construction, and operation, involving a large number of university and industrial contractors. Basic authorization was obtained from the President. With the general approval of the S-1 Committee of the Office of Scientific Research and Development (OSRD), and the Military Policy Committee, Major General L. R. Groves directed the general policies under which the Manhattan District carried on the work.

2. Basic Theory. - In 1938 O. Hahn and F. Strassmann discovered the phenomenon of nuclear fission in uranium. It was subsequently realized that the fission reaction was due to the uranium isotope of atomic weight 235, and that the reaction could probably be made to sustain itself as a chain reaction with the rapid release of tremendous quantities of energy. The problem was therefore presented of concentrating Uranium-235, which exists in natural uranium only to the extent of 0.714 per cent. The task is complicated because of the small difference in the atomic masses of U-235 and U-238, which difference must form the basis of the operating process. The method of gaseous diffusion is based upon the experimental finding of Thomas Graham in 1829 that the rate of effusion of gases through small apertures is inversely pro-

portional to their molecular weights. The only known feasible working substance for the process was uranium hexafluoride, UF_6, which can be easily volatilized. The process equipment installed at K-25 consists of a lengthy series or "cascade" of diffusion stages. The "converter" of each stage is subdivided into a cooler and "diffuser". The diffuser is a tank-like piece of equipment which encloses the "barrier". The barrier is the heart of the process, and consists of a thin, porous, metallic membrane containing billions of submicroscopic openings per square inch. The stage "B pump" supplies the converter continuously with undiffused gas from the stage above, mixed with diffused gas from the stage below. The cooler removes the heat of pumping and maintains a constant operating temperature. Conditions are so arranged that half of the gas fed to the converter diffuses through the barrier, becoming slightly enriched in concentration of the lighter component in accordance with Graham's Law, and is delivered by the stage "A pump" to the next higher stage. The remaining half leaves the converter, passes through the control valve, which maintains a constant converter operating pressure, and enters the suction of the next lower stage"B pump." Product material is withdrawn from the "top" of the cascade. Depleted waste leaves at the "bottom".

3. Planning of the Project. - In July 1941, OSRD contract OEMsr-106 was awarded to Columbia University, providing for investigation of the method of gaseous diffusion as applied to uranium isotope separation. Contract OEMsr-406 was next awarded to the M. W. Kellogg Company for further experimental and engineering investigation. After the preliminary production plant program had been reviewed by the OSRD S-1

Executive Committee and the Reassessment and Reviewing Committee, it was decided to construct a 4600 stage plant to produce 1 kilogram per day of U-235 at a concentration of 90 per cent. Arrangements for the work were concluded in secret letter contract W-7405-eng-23 awarded to the M. W. Kellogg Company on 14 December 1942. For security and accounting reasons, Kellogg created a totally-owned subsidiary, The Kellex Corporation, which was to be wholly devoted to the K-25 undertaking. Fundamental research was carried on at the SAM Laboratories of Columbia University under OSRD contracts OEMsr-106 and OEMsr-412, and, after 1 May 1943, under Manhattan District contract W-7405-eng-50. On 1 February 1945, responsibility for the SAM Laboratories was transferred to the Carbide and Carbon Chemicals Corporation under a modification of contract W-7405-eng-26. The Kellex contract W-7405-eng-23 also called for extensive research and development, as well as stipulating that that corporation have overall responsibility for planning, engineering, design, and development of the Project. A number of specific phases of the research program were assigned to various other laboratories as subcontractors. A large number of additional firms participated in the immense design and engineering program, under general Kellex supervision. British assistance was also obtained on various theoretical and design problems. After a thorough review of all phases of the Project from the standpoint of cost, completion dates, performance, and capabilities of possible plants, it was decided on 18 August 1943 to construct a plant to produce material at an isotopic concentration of 36.6 per cent U-235, and on 31 March 1945 the "K-27 Plant", a side feed addition plant, was authorized, in order to increase the production capacity of K-25.

Diffusion plant construction was accomplished principally by the J. A. Jones Construction Company (contract W-7421-eng-11), and Ford, Bacon, and Davis, Inc. (contract W-7407-eng-19), each under the supervision of Kellex, and each assisted by numerous subcontractors. Operated principally by the Carbide and Carbon Chemicals Corporation under contract W-7405-eng-26, the plant has been in production since March 1945.

4. Description of the Project. - The K-25 production plant is located at the northwest corner of the Clinton Engineer Works military reservation. The process area includes the main cascade of 2892 stages, housed in a series of 51 contiguous buildings arranged to form a single large "U"-shaped structure. Each building is subdivided into from three to fourteen six-stage "cells" which are the smallest individually operable units. Auxiliary facilities include systems for feed purification, purging, surge and waste handling, process gas recovery, and product removal. Service installations are also provided for maintenance facilities, and for supplying compressed air, specially dried air, cooling water, and special coolant, in accordance with process requirements. The conditioning area includes principally the conditioning building, in which a large number of cleaning, fluorinating, and maintenance operations are carried on. A sizeable florine generation plant is also located within this area, together with a disposal unit for spent conditioning gas, a nitrogen vaporization system, and a 270,000 pound per hour low pressure steam plant; The power plant area includes a boiler house for three 750,000 pound per hour coal-fired units designed to produce steam at 1325 pounds per square inch and 935°F, a turbine room for 14 turbo-generators with a combined rating

of 238,000 KW, a storage yard for 250,000 tons of coal, and suitable switch house and pump house facilities. The administration area includes miscellaneous office buildings, laboratories, station houses, a cafeteria, a dispensary, and a laundry. The K-27 Area is a structurally separate annex to the main process area, consisting of a 540-stage cascade complete with auxiliary facilities, and so connected with the main buildings as to form a "cascade of cascades". Sometimes referred to as "the largest physico-chemical process in the world", the K-25 plant represents the fruition of a research, development, design, and manufacturing program which was spread throughout the nation. The greater plant area encompasses some 5000 acres. The cascade "U" is one mile in perimeter and one quarter mile across. The size of the installation, which had required 60,000 carloads of equipment and supplies as of 1 January 1946, is typified by the following: the plant contains 7,500,000 square feet of geometric barrier area, 8,700 process and coolant pumps, 100 miles of process piping, 130,000 specially engineered instruments, and 500,000 valves. Auxiliary facilities include one of the largest dry air installations ever constructed and a 170,000,000 gallon per day cooling water plant. The power plant is the largest steam-electric station ever constructed in a single operation, and a 200,000 gallon plant inventory is maintained of specially developed process coolant.

5. Major Problems. - A host of problems of unparalleled scope and complexity were inherent in the K-25 program. Outstanding amoung these were the evolution, development, and large scale production of barrier, a totally novel and highly specialized material. DELETED DOE b(3)

SECTION 2 - BASIC THEORY

2-1. Nuclear Fission. - With the momentous discovery by the German scientists, O. Hahn and F. Strassmann, in 1938, of the phenomenon of nuclear fission in uranium, a turning point in the course of modern physics was reached. The effect was one in which the element uranium was converted or transmuted into different elements, mass was converted into energy according to the predictions of Albert Einstein, new elements of transuranic atomic numbers were synthesized, and a tremendous reservoir of hitherto unleashed power was uncovered. With the subsequent realization that the breaking up of a uranium atom was initiated under proper conditions by the impact of a neutron, and further that several neutrons were released at high speed among the fission products, it was realized that this vital reaction might be made to sustain itself as a chain reaction. In other words, the conversion of part of the mass of a nucleus into energy could be multiplied billions of times within a very small fraction of a second. The fission phenomenon was subsequently shown to be due to the Uranium-235 isotope, and scientists turned their attention to the study of methods for separating this isotope from the more abundant Uranium-238.

2-2. Concentration of Uranium-235. - The element uranium exists naturally in the form of various compounds all of which contain the metal as U-238 - 99.28 per cent, U-235 - 0.714 per cent, and U-234 - 0.006 per cent. This third component, present in such a small amount, will be disregarded in further discussions, and the concentration problem may be visualized as one of separating U-235 from U-238. The

goal of the Manhattan District was to make available for military use the atomic energy released as a product of the fission reaction. The scope of the K-25 Project includes the enhancement on a large scale of the isotopic concentration of U-235 in uranium by means of the process of Gaseous Diffusion.

a. Separation of Isotopes. - The task of separating isotopes is well known to be complicated by the very nature of the problem. Thus isotopes of an element are identical as far as atomic number, and therefore chemical properties, are concerned. The distinction is one of structure and weight of the nucleus. Attempts at separation must be based upon differences in atomic weight. Methods employed must be physical rather than chemical, and further, they must make use of a difference between isotopes which is very slight; that is, the atomic weights of elements ordinarily differ by only a small number of mass units. The problems are particularly difficult in the case of uranium, which is the heaviest of all atoms in the classical periodic table. Thus a difference of three mass units between the atom of U-235 and that of U-238 amounts to only 3 parts in 238 (using the more abundant isotope as a basis for calculation) or 1.3 per cent. Slight as this difference is, it is significant, and within the Manhattan District, the separation has been effected by means of Thermal Diffusion (Book VI), by the Electromagnetic Method (Book V), and by the Gaseous Diffusion Method, which is the object of the K-25 Project.

b. Gaseous Diffusion.- A more accurate designation would be "molecular effusion" since the method is based upon the effect noted by Thomas Graham in 1829 wherein molecules in the gaseous state

tend to flow or "effuse" through narrow apertures at rates which under given conditions of temperature and pressure, are inversely proportional to the square root of the density or molecular weight. Thus, if a mixture of gases is confined within a container possessing a small opening, the lighter molecules will tend to escape more rapidly than the heavier ones, and a means is available for separating molecules according to mass. It is important to note that the size of the aperture must be of the same order of magnitude as the distance travelled by individual molecules between collisions with one another. Larger openings would permit ordinary "viscous" flow of the fluid mass without any separative effect.

2-3. Application of Theory.

a. Process Material. - Elemental uranium is a dense, heavy metal. The process calls for a gaseous process material, and the first requirement is therefore to obtain a compound of uranium in such form that it will be susceptible to processing by this method. As will appear in more detailed discussion (Vol. 2), the material, uranium hexafluoride (UF_6), presented itself, not without a series of important disadvantages, but nevertheless as the only known uranium-containing substance which could be handled in the gaseous state. Since the atomic weight of fluorine is 19, the molecular weight of $U^{235}F_6$ is 349, and the molecular weight of $U^{238}F_6$ is 352. It is important and fortunate that the situation is not complicated by variation in the atomic weight of fluorine, i.e., fluorine possesses no isotopes of its own. Thus the difference of three mass units between the atoms of U-235 and U-238 results in a difference of three mass units between the molecules of $U^{235}F_6$ and $U^{238}F_6$. Having chosen UF_6 as the working substance, how-

designated by γ, was generally adopted throughout the Project for correlating barrier porosities. Further studies showed that the permeability of barrier is made up of two parts. One part (γ_o) is nearly independent of the gas used, and the test conditions of pressure and temperature. The second part is definitely a function of these variables. Thus, it was found that when observed permeability was plotted against "pressure sum" (fore pressure plus back pressure), a nearly straight line was obtained which could be represented by the equation:

$$\gamma = \gamma_o [1 + S(P_i + P_o)]$$

in which:

γ = permeability
Pi = fore pressure
Po = back pressure
γ_o = extrapolated value of permeability at zero pressure sum
S = the "slope factor"

The porosity properties of a barrier can be specified by giving values for γ_o and S.

Barrier Type	γ_{16}	S
WB TL WL	DELETED	

DOE b(3)

Permeability is dependent upon the operating pressure, increasing in magnitude as the difference between fore pressure and back pressure is increased. Permeability is also a function of barrier structure, increasing both with the number and size of the holes. A barrier of a certain permeability with a large number of fine apertures will show a greater separation factor than one with a smaller number of larger holes. It is necessary to specify both upper and lower limits for permeability, since if the permeability rises above the upper limit, or falls below the lower limit chosen for plant design, process pump efficiency decreases. Process pumps become unstable if their intake falls below a specified limit, and as permeability increases, either the horsepower of the process pumps must increase, or the total pressure of the plant must decrease.

b. Chemical Properties.

(1) Plugging Characteristics. - The barrier must be chemically inert to uranium hexafluoride, a very aggressive substance. Reaction of the barrier material with process gas can lead to serious reduction in permeability by growth of reaction products within the pores. Moreover, corrosion at other points in the process system can form solid products which may lodge in the apertures and produce the same result. Since six months was considered to be the minimum allowable life from the point of view of replacement and plant maintenance, a tolerable plugging rate for barrier was set at 0.16 per cent per day.

1. Total Uranium Received

Included in this graph are receipts of such items as billets, extruded rods, unbonded and bonded slugs and machined pieces. In computing the weight of uranium in rods in terms of equivalent metallic billets, a factor of 0.93 has been applied to the weight of rods. Similarly, a factor of 0.83 has been employed in converting from uranium slugs, bonded and unbonded, to rods, or an overall factor of 0.775 in deriving billets from slugs. In converting from machined pieces to billets, a factor of 0.78 has been used.

the group except Lt. Collins left Tokyo by air for the United States, arriving at Hamilton Field, California, at 3:00 p.m. on 15 October 1945, after stopovers at Tinian, Kwajalein and Hickam Field, Honolulu.

(References 4, 5, 6.)

6. Itinerary of the Hiroshima Group.

The group headed by Lt. Colonel H. L. Friedell was transferred from Tinian to Guam and thence to Zamboanga in the Philippines, where they awaited transportation by air to Japan. The group was delayed by a series of typhoons and did not enter Hiroshima until about 26 September 1945 (about ten days before the date of departure).

This group spent about one week in Hiroshima and then returned to Tokyo by train, after considerable hardship; there they joined the Nagasaki group and returned with them to the United States.

(Reference 5.)

7. Physical Damage in Hiroshima and Nagasaki.

a. Survey Methods. The surveys of physical damage were made in both cities by the Army Engineers and civilian physicists, who made observations, took photographs and collected specimens and statistics.

The scientists used various ingenious methods to calculate the peak pressures exerted by the atomic blasts at different points, from evidence which was still available. The peak pressures were calculated by Dr. W. G. Penney (British scientist from Los Alamos), from crushed empty vessels, such as oil drums or gasoline cans; from the bending of flag poles, or lightning conductors, away from the blast; and from overturned memorial stones. These pressures were checked against theoretical predictions and further checked against the readings obtained by the measuring instruments which were dropped by parachute at each atomic attack. From these pressure calculations, the

and for a long time after the explosion, as well as the uncertainty regarding the actual population before the bombing, contributed to the difficulties in obtaining reliable information.

b. Estimates of Total Casualties.

(1) The best available figures for the estimated total casualties in each city, as compiled by the Manhattan District, are as follows:

Total Casualties

	Hiroshima		Nagasaki	
	Number	Percent	Number	Percent
Pre-raid Population	255,000	100	195,000	100
Dead	66,000	26	39,000	20
Injured	69,000	27	25,000	13
Total Casualties	135,000	53	64,000	33

(The estimates of the Medical Division of the U. S. Strategic Bombing Survey are higher: In Hiroshima, 80,000 dead and 80,000-100,000 injured; in Nagasaki, 45,000 dead and 50,000-60,000 injured. Reference 13.)

It is generally believed that the energy of the Nagasaki explosion was greater than the energy of the Hiroshima explosion, yet the above figures show that the effects in terms of total casualties were considerably greater in Hiroshima. This was caused not only by the topography and the physical layout of the two cities, but also by unexpected chance circumstances: just previous to the bombing of Hiroshima plans were being made for the evacuation of unnecessary persons, and on the day of the bombing approximately 40,000 extra people had been brought into the center of the town for instructions on these evacuation plans; in Nagasaki, on the other hand, similar evacuation

plans had been carried out a week before the bombing, and the population in the bombed areas had been reduced. Also, many of the families of those working in the mills and plants lived outside of the bombed area. It may be noted that in Nagasaki particularly the numbers of the dead were determined by the numbers of bodies actually incinerated by the clean-up squads and did not include the great number burned in the buildings, whose skeletons were mixed up with the ashes and ruins; nor was there any good count of those refugees who died in the suburbs, particularly in the first few weeks. (References 1, 3.)

(2) The relation of total casualties to the distance from the center of explosion (the point referred to as "X"), in Nagasaki, is shown in the following estimates, based on the casualty figures first obtained by the Manhattan District (Reference 1):

Relation of Total Casualties to Distance from "X".

Distance from "X", feet	Killed	Injured	Missing	Total Casualties	Killed per Square Mile
0-1,640	7,505	960	1,127	9,592	24,700
1,640-3,300	3,688	1,478	1,799	6,965	4,040
3,300-4,900	8,678	17,137	3,597	29,412	5,710
4,900-6,550	221	11,958	28	12,207	125
6,550-9,850	112	9,460	17	9,589	20

(The summation of total casualties in this table, 67,765, was revised by later estimates to 64,000).

(3) There is no way of transposing these figures mathematically to percentages of mortality, because no data have been obtained to show the pre-raid population at the various distances from "X".

A calculation made by the British Mission to Japan, however, based on a preliminary analysis of the study of the Joint Medical Atomic Bomb Investigating Commission, gives the estimated percentages of mortality at other distances, as follows:

Percent Mortality at Various Distances

Distance from "X" in yards	Percent Mortality
500	93%
1,000	66
1,500	37
2,000	18
2,500	6
3,000	1
3,500	0

(From curve, "in Japan", on diagram headed "The More Important Effects of Atomic Bombs on People and Their Homes", in Report of the British Mission to Japan, "The Effects of the Atomic Bombs at Hiroshima and Nagasaki", 1946, page 21.)

Plotting these distances and percentages to suitable scales produces a smooth curve and it is probable that this curve would not be very seriously at variance with the curve which could be produced from the actual facts, if the necessary population figures were available and if proper allowance were made for the layout and topography of the cities and for the large element of chance which inevitably influences the results produced by all explosives. It is common knowledge that freakish results are sometimes the rule rather than the exception in high explosive detonations.

Because of the peculiar psychology of the Japanese who wanted to please the interrogator, one must view with suspicion a good deal of the information gathered by subsequent parties on the location of survivors at the time of the explosion, for the number of unscathed survivors from the center increased with time. Actually the shock of the experience frequently

caused an amnesia in survivors and very few near zero escaped lethal gamma ray exposure.

(4) It was probably inevitable that the great majority of total fatalities should have occurred immediately after the bombing. The causes of many of the deaths could not be definitely determined, and of course many persons near the center of explosion suffered fatal injuries from more than one of the bomb effects. The possible causes of the immediate deaths were, principally, in order of importance: burns, mechanical injury, and gamma radiation, but it seems unlikely that radiation alone would be immediately fatal. Early estimates of the Japanese, for what they may be worth, are shown in the following table (Reference 1):

Causes of Immediate Deaths

City	Cause of Death	Percent of Total
Hiroshima	Burns	60%
	Falling debris	30
	Other	10
Nagasaki	Burns	95%
	Falling debris	9
	Flying glass	7
	Other	7

It is obvious that the percentage figures for Nagasaki include duplications, because the percentages add up to 118, whereas there are no duplications in the figures for Hiroshima. This may account, to some extent, for the wide divergence of the results as estimated for each city, but it is probable that more important reasons for these differences are the variations to local conditions, and the human equation. Different estimators would certainly reach different results in interpreting the evidence for theoretical evaluations of this kind.

the Chief, Defense Atomic Support Agency, Washington 25, D. C. AEC and AEC contractor personnel should forward suggestions to the Director, Division of Classification, U. S. Atomic Energy Commission, Washington 25, D. C.

c. Those portions of this Guide that provide positive guidance may be used in day-to-day classification determinations. Requests for classification guidance should be forwarded through channels to the appropriate DOD or AEC agency described in 2b. above.

3. Basic Policy

a. The principle underlying declassification policy is to achieve a balance between two aims: (a) promoting the common defense and security by maintaining at a minimum the declassification of knowleuge concerning the non-peaceful applications of atomic energy and (b) promoting the scientific and peaceful applications of atomic energy to the maximum extent consistent with the common defense and security.

b. Weapons Information: Of all the types of classified atomic energy information, that which is of significance (requiring classification and safeguarding) to nuclear weapons is the most important from the point of view of the national security. Weapons information is inherently classified. In this field, retarding the progress of inimical nations is particularly important. Therefore, the declassification or downgrading of any information is justified only when it makes a contribution to our own progress which clearly outweighs the risk to the national defense and security of disclosing the information.

However, within the area of nuclear weapons information there is a wide range of sensitivity. Of special significance are the following:

Str Wedemeyer?

sively tested at Dahlgren beginning on December 3, 1943.

In September, 1943, the fast-implosion model was proposed by John Von Neumann as an alternative to the slow implosion. As it became clear that this model was a promising one, preliminary planning for converting it into a bomb was begun. A preliminary estimate of 59 inches diameter and 9000-pound weight was made by Von Neumann and Ramsey, and on this basis the Bureau of Standards bomb group was asked to design suitable fairing and stabilizing fins for such a bomb.

OK

In the Fall of 1943 it became apparent that plans for full-scale tests should be started. In view of the critical shortage of B-29's it was first proposed that a British Lancaster be used for the test work, even though a B-29 would almost certainly be used as the combat ship. The Air Force, however, wisely recommended that a B-29 be used for the test work as well, both to avoid non-standard maintenance and to accumulate experience in B-29 operations with such a bomb. In order that the aircraft modifications could begin, Parsons and Ramsey selected two external shapes and weights as representative of the current plans at Site Y (Project Y). One of these was 204 inches long with a maximum diameter of 23 inches and was a model for the current gun assembly. The other was 111 inches long and 59 inches in diameter, corresponding to a fast-implosion assembly. For security reasons, these were called by the Air Force representatives the "Thin Man" and "Fat Man", respectively; the Air Force officers tried to make their phone conversations sound as though they were modifying a plane to carry Roosevelt (the Thin Man) and Churchill

(the Fat Man). Models to these dimensions were ordered from Detroit. Modification of the first B-29 officially began November 29, 1943. Colonel R. C. Wilson was Army Air Forces Project Officer for all aspects of the program, Colonel D. L. Putt at Wright Field was in charge of the division under whose supervision the modification was done, and Captain R. L. Roark was Project Officer in charge of modification.

Tests with the modified aircraft and full-scale dummy bombs were begun at Muroc, California on March 3, 1944. Brode's fuzing group, Bainbridge's instrumentation group, and the delivery group participated in these tests. Coordination of the activities of the different groups in these and subsequent field tests was a responsibility of Ramsey's delivery group. The purpose of the tests was to check the suitability of the fuzing equipment, the stability and ballistic characteristics of the bombs, the facilities then available for field work, and the suitability of the aircraft to carry and drop the bombs. After four weeks of delay, due to torrential rain on the Mojave Desert and aircraft troubles, a series of tests was completed. The negative results of most of these tests thoroughly justified preliminary tests at such an early date. The fuzes proved to be unreliable and, on the basis of these results, an investigation of the possibility of adapting an AFS-13 fighter tail-warning radar to this use was begun. The Thin Man proved to be very stable in its flight, but the Fat Man -- with a tail that the Bureau of Standards bomb group thought would be extremely stable --, proved to wobble badly with its axis departing 20° from the line of flight. Although the B-29 release mechanism worked satis-

factorily for the Fat Man, it failed completely for the Thin Man. Four of the units were bad hang-ups with delays up to 10 seconds, and the final drop was 20 minutes premature while the plane was still climbing to altitude. The bomb in this case fell onto the bomb-bay door which was badly damaged, when the door had to be opened to jettison the bomb. With this accident, the first Muroc tests were brought to an abrupt and spectacular end.

Between the end of the first tests and June 1944, all groups worked to correct the faults demonstrated in the first tests.

DOE b(3)

Detailed designing of this shorter model was begun during this period under the supervision of E. M. McMillan and F. A. Birch. Because of the contrast in dimensions with the Thin Man, this model finally acquired the appropriate name of Little Boy. At the same time the detailed designing of the 1222 form of Fat Man assembly was begun.

DOE b(3)

Tests at Muroc were resumed in June, 1944. These tests confirmed previous results in that the first form of fuze being developed

[redacted]

at Michigan was not satisfactory. The first two APS-13's became available to Project Y during the test, and two haywire drop tests (genuine baling wire was actually used) were made with a field adaptation of this equipment to fuzing. The earlier of these provided the first completely satisfactory fuzing test; and, although the second failed, it was probable that the failure was in some of the hastily prepared auxiliary equipment. The Fat Man, its tail assembly modified from the original circular shroud to a square shroud 59 inches on a side, still proved unstable. As a desperate last resort, Captain David Semple, Project Bombardier, suggested a drop be made with internal 45° baffle plates welded into the inside of the shroud as a field modification. To everyone's surprise, this modification was successful, the bomb being completely stable in its flight and the ballistic coefficient being improved rather than decreased as anticipated. No release failures were experienced in the tests.

Adm Ashworth says this was Parsons suggestion. 7/11/78

From the end of these tests until October, 1944 when similar field tests were resumed, a strenuous program of design and procurement was under way at Site Y to obtain units that could be used as components of an actual atomic bomb rather than units that were merely ballistic models. Three basically different models were on hand at this time. One was the Little Boy model of the U^{235} gun assembly, another was the 1222 Fat Man model of implosion assembly, and the third was a model which evolved into the finally adopted 1561 Fat Man implosion assembly. The latter arose from a redesign for the purposes of simplifying the assembly problem (the assembly of 1222 required the insertion of more than 1500 bolts) and of improving

Figure 14

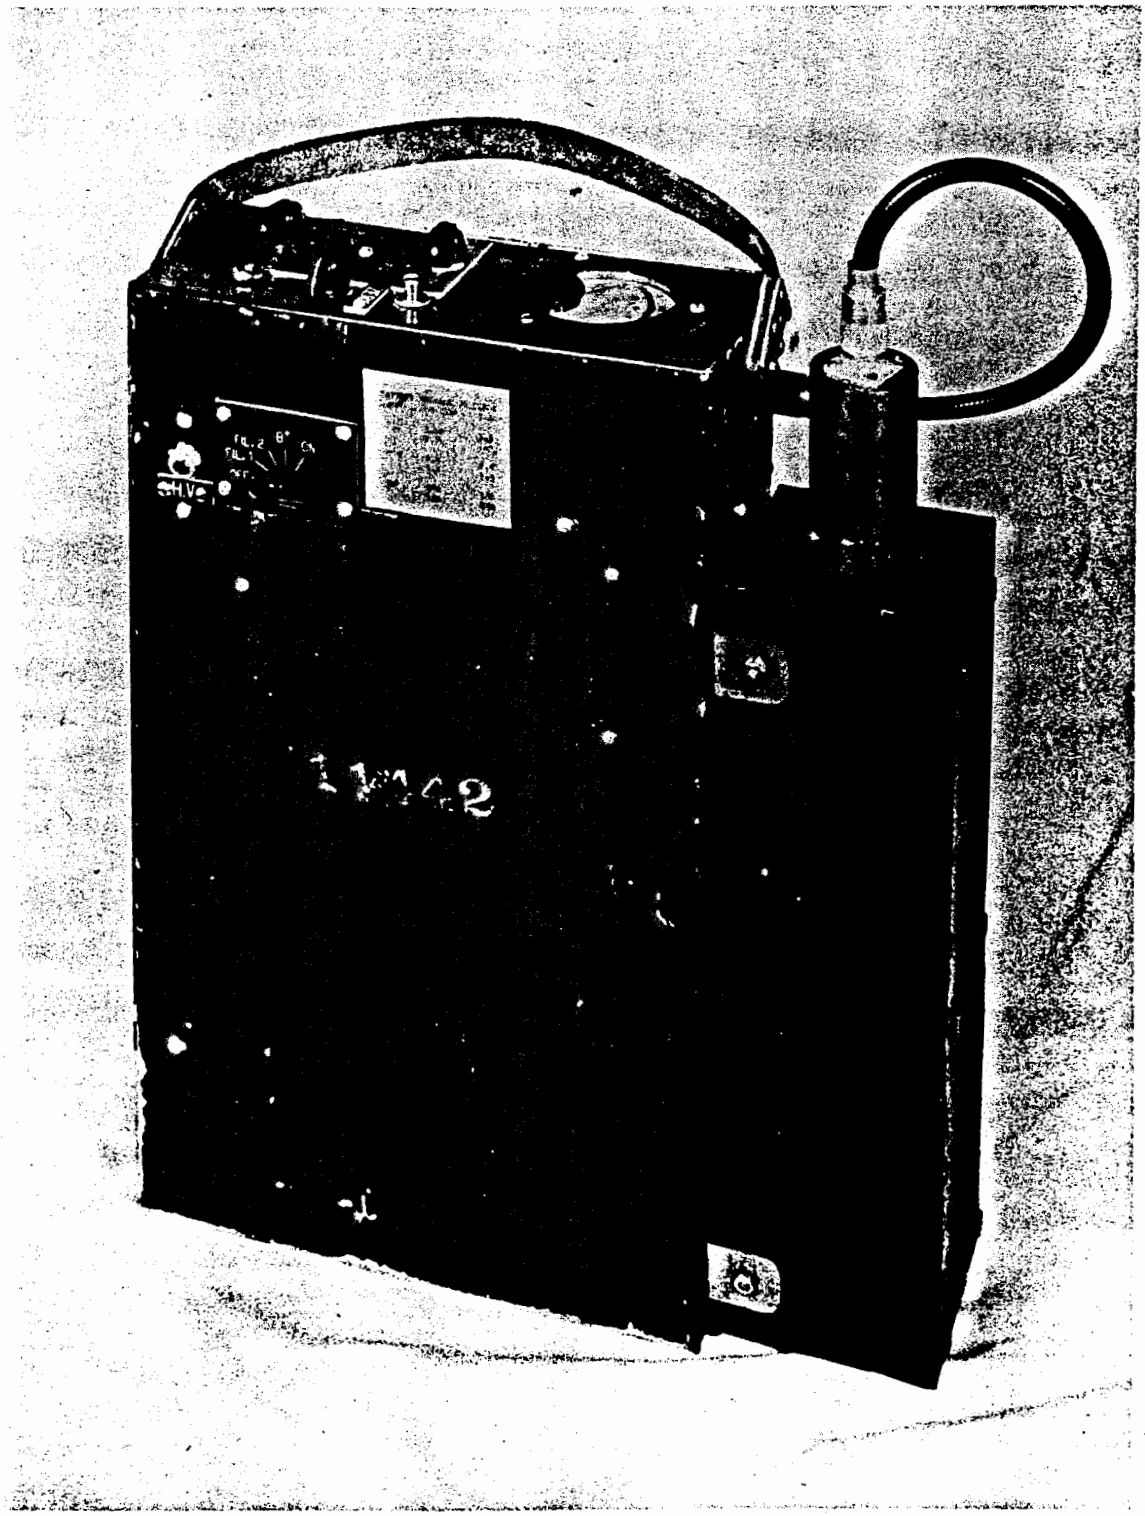

Figure 14

CHAPTER 3

MECHANICAL DESIGN OF MODEL 1561 FAT MAN

A. H. Machen

3.1 INTRODUCTION

This Chapter is concerned with the design of the case, the equipment supports, the lugs, and other external parts of the 1561 model Fat Man. The design of the pit containing the active material for this bomb is discussed in the preceding chapter of this Volume; and the design of the high-explosive components is discussed in Volume XI of the Los Alamos Technical Series.

Figure 1 is an artist's drawing of an early form of the Fat Man model. From that Figure, it can be seen that the model consisted essentially of a large sphere containing the explosives and active material, mounting provisions for auxiliary electronic equipment, an outer armor steel cover, lift lug, and a stabilizing tail assembly. This Chapter will discuss these components of the assembly. A collection of the mechanical drawings of the final form of the 1561 model Fat Man that was used in combat may be found in LA-392.

3.2 DESIGN OF THE SPHERE

Design of the sphere was started with the following specifications:

(1)

(2) A size within the limits of the bomb bay of a B-29

airplane with a fall angle of five degrees;

(3) Provision of detonation holes for more than one detonation pattern.

The first model was the 1222 (Figure 2). Its spherical case was divided by great circles into twelve equal pentagons bolted together by edge flanges; machining these pentagons to a close enough tolerance to permit bolting-up into a complete sphere turned out to be highly impractical.

DOE b(3)

This model was further complicated by a steel case consisting of twenty triangles secured to the sphere by some eleven hundred bolts screwed into holes radially drilled and tapped into the flanges of the pentagon. A steel lift-lug pad, designed to distribute the lug load out into the spherical case, was provided and secured to the sphere at the apex of the top five pentagons.

DOE b(3)

A complete departure from the 1222 pentagon structure was made in the 1291 model (Figure 3) using the same polar cap and belt-band design that was used in the final model. The 1291 model consisted of three spherical zone segments bolted together by 18 bolts screwing into tapped flanges to form a belt section of the sphere. The sphere was completed by two polar caps bolted to the tapped flanges of the belt section.

DOE b(3)

staked into holes drilled in the case for fast, easy mounting of the 110 wire harness clips necessary to hold the coaxial detonator cables (Figure 5).

3.3 MOUNTING OF ELECTRONIC INSTRUMENTS

The mounting of the instruments in the early stages of 1222 design presented few problems. For example, the firing circuit was a small box weighing a few pounds, whereas the final unit was a cast dural tub, weighing about 300 pounds. All of the instruments of this first unit were supported on a single tubular mount attached to the aft side of the sphere (Figure 6), and it was not until after the start of the 1560 model that any of the instruments were placed forward of the sphere. By this time, all the space within the ellipsoidal covers, fore and aft, was occupied by firing and fuzing circuits. The tubular mounting brackets were used fore and aft on the 1222, but discarded on the 1560. A dural cone was designed that would tie into the polar cap bolts, supporting the 300-pound firing circuit box in front and a panel of fuzing instruments aft without danger of vibration. Fast, accurate assembly was kept in mind throughout this design; although the bomb could be a hand-tailored job in most respects, speed was very important in the assembly of the hot model.

A mounting plate was provided for the firing-circuit charging equipment. This plate, mounted in the nose of the front ellipsoid, was accessible through the removable nose plate, and provided a means of battery installation after assembly of the bomb (Figure 7). All instrument plates required constant attention, since changes and rearranging of parts made new layouts necessary to check clearances

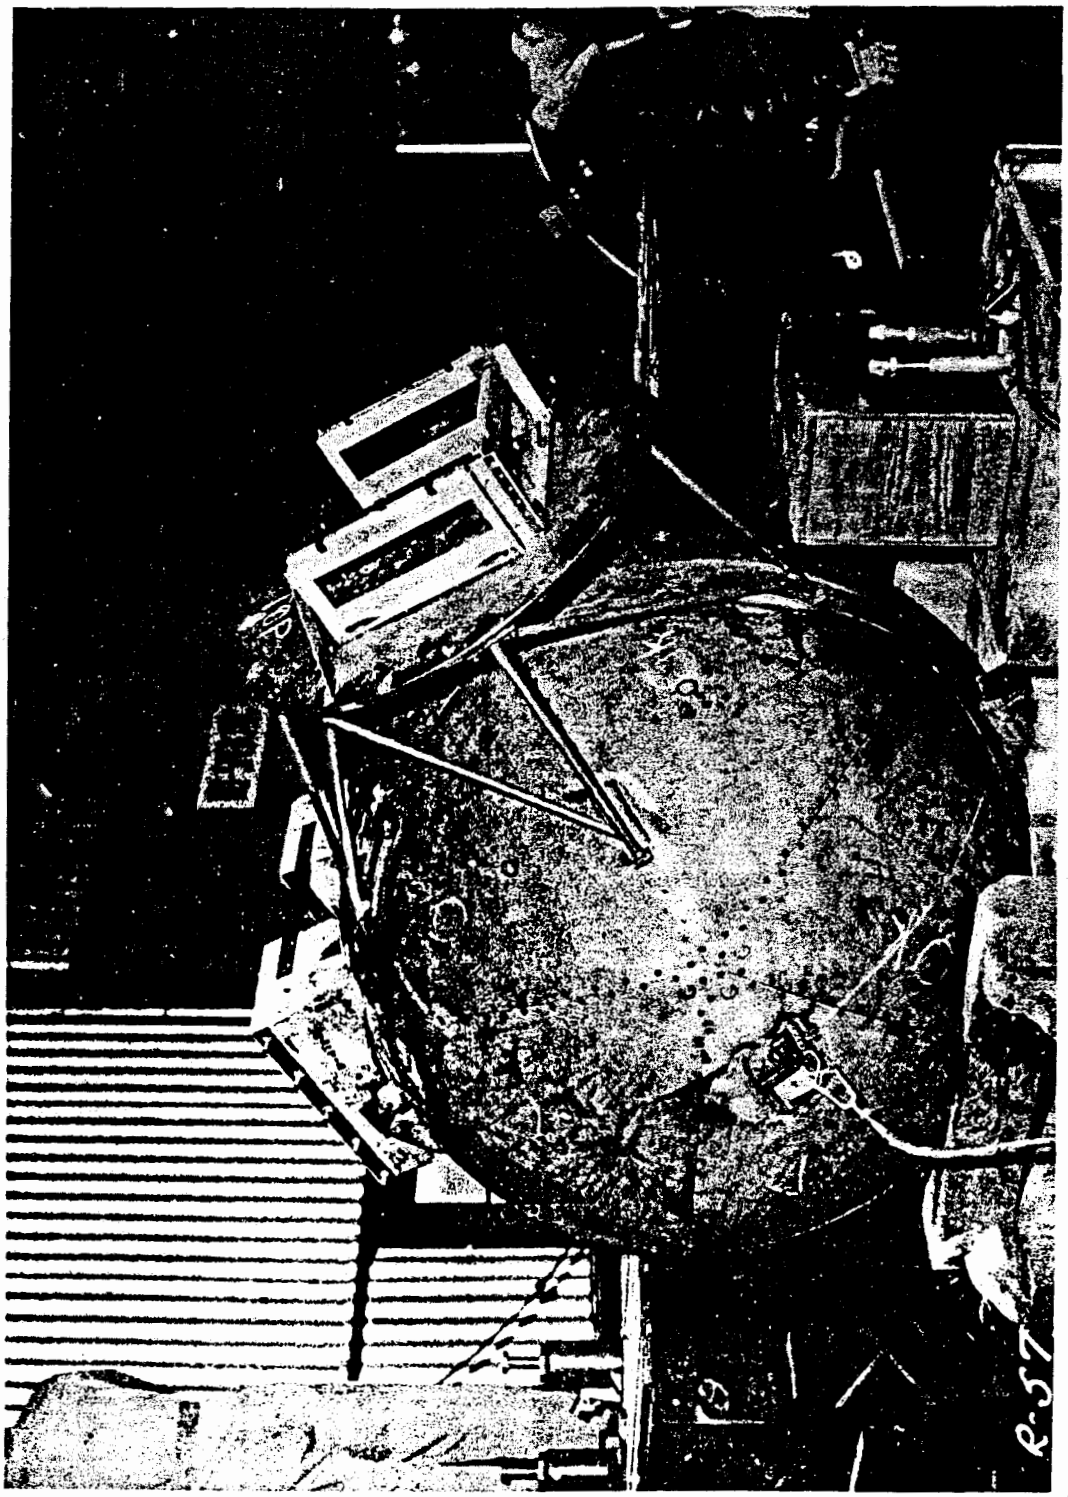

Figure 6

CHAPTER 5

ATOMIC-BOMB PROJECT AIRCRAFT

S. H. Dike

5.1 AIRCRAFT USED FOR ATOMIC-BOMB DELIVERY

The first bomb dropped in connection with this project was released from a TBF at Dahlgren Naval Proving Ground, Virginia, on August 13, 1943. This test, witnessed by N. F. Ramsey, was for ballistic data only. The first drop made in connection with fuze research was made from an SNB-1 (AT-11) at Dahlgren on December 3, 1943.

In the early days, several types of aircraft were considered for carrying the atomic bomb. The shape of the bomb then was very different from either of the two final types. The British Lancaster and our own B-29 were the two planes most seriously considered for the final delivery job. In the early summer of 1943, the B-29 was a new airplane; its performance was still more or less unknown and production rates were not definitely planned.

It was decided in November, 1943, to modify a B-29 at Wright Field for project use. Accordingly B-29 No. 42-6259 was procured. This was the 69th Wichita production airplane.

At that time, there were two distinct types of bombs which Project Y wished to drop. These were known as the "Fat Man" (Figure 1) and the "Thin Man" (Figure 2). The "Thin Man" became obsolete later in the program and evolved into the "Little Boy".

CHAPTER 6

HISTORY OF PROJECT A AT TINIAN

by

N. F. Ramsey

6.1 INTRODUCTION

The Project A organization at Tinian consisted of the following: Officer-in-Charge, Commodore W. S. Parsons USN; Scientific and Technical Deputy to Officer-in-Charge, N. F. Ramsey; Operations Officer and Military Alternate to Officer-in-Charge, Commander F. L. Ashworth, USN; Fat Man Assembly Team headed by Roger S. Warner Jr.; Little Boy Assembly Team headed by Commander Francis A. Birch, USNR; Fuzing Team headed by E. B. Doll; Electrical Detonator Team headed by Lt. Commander E. C. Stevenson, USNR; Pit Team headed by Phillip Morrison and C. P. Baker; Observation Team headed by Luis W. Alvarez and Bernard Waldman; Aircraft Ordnance Team headed by Sheldon H. Dike; and Special Consultants consisting of Robert Serber, W. G. Penney and Captain J. F. Nolan, AUS. The team leaders formed a Project Technical Committee under the chairmanship of Ramsey to coordinate technical matters and to recommend technical actions to Captain Parsons. The following persons were team members:

Agnew, Harold
Anderson, David L., Ensign
Bederson, Ben B., T/5
Bolstad, Milo M.
Brin, Raymond, T/Sgt.
Caleca, Vincent, T/Sgt.
Camac, Morton, T/Sgt.
Carlson, Edward G., T/Sgt.

Collins, Arthur, T/4
Dawson, Robert, T/Sgt.
Fortine, Frank J., T/Sgt.
Goodman, Walter, T/3
Harms, Donald C., T/3
Hopper, J. D., Lt.
Kupferberg, J., T/Sgt.
Johnston, Lawrence H.
Langer, Lawrence M.
Larkin, William J., T/Sgt.
Linschitz, Henry
Machen, Arthur B.
Mastick, Donald, Ensign
Matthews, Robert P., T/3
Miller, Victor A., Lt. (j.g.)
Motechko, L. L., T/3
Murphy, William L., T/Sgt.
Nooker, Eugene L., T/Sgt.
Olmstead, T. H.
O'Keefe, Bernard J., Ensign
Perlman, Ted
Prohs, Wesley R., Ensign
Reynolds, George , Ensign
Russ, Harlow W.
Schreiber, R. E.
Thorton, Gunnar, T/Sgt.
Tucker, J. L., Ensign
Zimmerli, Fred, T/4

Although not strictly members of Project A, the following were closely associated with the work of the Project: Rear Admiral W. R. Purnell, USN, representative of the Atomic Bomb Military Policy Committee; Brig. General T. F. Farrell, representative of Major General L. R. Groves; Colonel E. E. Kirkpatrick, alternate to General Farrell and the Officer in Charge of Construction; Colonel P. W. Tibbets, Commanding Officer of the 509th Composite Group; Lt. Colonel Peer de Silva, Commanding Officer of the First Technical Service Detachment, which served as administrative, security and housing organization for Project A; and Major Charles Begg, Commanding Officer of the First Ordnance Squadron, Special.

Although preliminary construction at Tinian began in April, 1945,

intensified technical activities were not started until July. The first half of July was occupied with establishing and installing all of the technical facilities needed for assembly and test work at Tinian. After completion of these technical preparations, a Little Boy unit was assembled and, with the dropping of unit L1 on July 23, the Tinian base became fully operational for Little Boy tests. In the first test, a dummy Little Boy was fired in the air by radar fuze. Here, as in subsequent Tinian tests, excellent results were obtained. The second Little Boy, Unit L2, was dropped on July 24, and a third, Unit L5, on July 25. The only remaining phase of the Little Boy mission, and included as part of the test, was a check of facilities at Iwo Jima for emergency reloading of the bomb into another aircraft. Since the Iwo Jima facilities were not ready until July 29, this test was postponed until then. On July 29 a completely successful test of the Iwo Jima facilities was completed. The plane landed with the L6 Unit at Tinian so that it could be used in the final rehearsal maneuvers. On July 31 the plane with the L6 took off accompanied by two observation planes. The planes flew to Iwo Jima where a rendezvous was made, and then returned to Tinian where the bomb was dropped and observed to function properly. After the release of the bomb all three aircraft rehearsed the turning maneuvers which would be used in combat. With the completion of this test, all tests preliminary to combat delivery of a Little Boy with active material were completed.

The first Fat Man test, unit F13, was made on August 1, 1945. This unit used cast plaster blocks, electronic fuzing, eight electric detonators, Raytheon detonating unit and informers and smoke puffs

on the operation of the detonators. The test showed that all essential components of the bomb functioned satisfactorily. A second inert Fat Man, F18, similar to F13, was prepared and loaded into a B-29 for drop on August 3. However, due to lack of information at Tinian of the results of the Wendover tests on the adequacy of the venting in the sealed Fat Man, the unit was unloaded and the barometric switches modified so that this information would be obtained on unit F18. In its modified form the F18 unit was dropped on August 5. All components functioned satisfactorily and the venting was adequate for the internal pressure to close a barometric switch set for 17,000 feet pressure altitude 17 seconds before impact. The only remaining preliminary Fat Man test was unit F33, a replica of the active unit, except for the lack of active material and the use of lower quality high explosive lens castings. The components for the F33 unit arrived at Tinian at 1230 on August 2 and preliminary assembly was begun the same day. Although the F33 unit was fully assembled by August 5, it was not dropped until August 8 due to absence of key crews and aircraft on the final Little Boy mission. A test was then conducted as a final rehearsal for the delivery of the first live Fat Man. Both the rehearsal operation and the detonation of the unit were completely satisfactory.

On July 26, the U^{235} projectile for the Little Boy was delivered by the cruiser INDIANAPOLIS. The U^{235} target insert arrived in three separate parts in three, otherwise empty, Air Transport Command C-54's during the evening of July 28 to 29. All three had arrived by 0200 July 29. Since the earliest date previously discussed for combat delivery of the Fat Man was August 5 (at one time the

official date was August 15). Parsons and Ramsey cabled General Groves for permission to drop the first active unit perhaps as early as August 1, with August 2 being more probable since poor weather was forecast for August 1.

Although the active Little Boy unit, No. L11, was completely ready in plenty of time for an August 2 delivery, the weather was unfavorable. The first, second, third, and fourth of August were spent in impatient waiting for good weather. Finally, on the morning of August 5 word was received that the weather should be good on August 6. At 1400 on August 5 General Lemay officially confirmed that the mission would take place on August 6.

The Little Boy was loaded onto its transporting trailer at 1400 on August 5 and, with an accompanying battery of photographers, was taken to the loading pit. The B-29 was backed over the pit at 1500 and the L11 unit loaded shortly thereafter. The aircraft was then taxied to its hard stand where final testing of the unit was completed. By 1800 all was ready. Between then and take-off, the aircraft was under continuous watch both by a military guard and by representatives of the key technical groups.

Final briefing was at 0000 of August 6. Following this, and an early breakfast, the crews assembled at their aircraft. There, amid brilliant floodlights, pictures were taken and retaken by still and motion picture photographers (as though for a Hollywood premiere). For the mission Colonel P. W. Tibbets was pilot of the B-29 (named the Enola Gay) which carried the bomb, Major Thomas Ferebee was bombardier, Captain W. S Parsons was bomb commander, and Lt. Morris Jepson was electronics test officer for the bomb. L. Alvarez,

Bernard Waldman, Harold Agnew and Larry Johnston rode in the accompanying observation aircraft.

The progress of the mission is best described in the log which Captain Parsons kept during the flight:

Captain Parsons' log:

August 6, 1945

0245	Take off
0300	Started final loading of gun
0315	Finished loading
0605	Headed for Empire from Iwo Jima
0730	Red plugs in (these plugs armed the bomb so it would detonate if released)
0741	Started climb Weather report received that weather over primary and tertiary targets was good but not over secondary target.
0838	Leveled off at 32,700 feet 30,750 IA on 31060' True (Nav Log)
0847	All Archies (electronic fuzes) tested to be O.K.
0904	Course west
0909	Target (Hiroshima) in sight
0915 1/2	Dropped bomb (originally scheduled time was 0915) Flash followed by two slaps on plane. Huge cloud.
1000	Still in sight of cloud which must be over 40,000 high
1003	Fighter reported
1041	Lost sight of cloud 363 miles from Hiroshima with the aircraft being 26,000 feet high. 25,960 IA

The crews of the strike and observation aircraft reported that 5 minutes after release a low 3 mile diameter dark grey cloud hung over the center of Hiroshima, out of the center of this a white column of smoke rose to a height of 35,000 feet with the top of the cloud being considerably enlarged.

Four hours after the strike, photo-reconnaissance planes found that most of the city of Hiroshima was still obscured by the cloud created by the explosion although fires could be seen around the edges. The following day excellent pictures were obtained showing the tremendous magnitude of the power of a single atomic bomb, which completely destroyed 60 percent of the city of Hiroshima.

The first Fat Man with active material, unit F31, was originally scheduled for dropping on August 11 local time (at one time the schedule called for August 20). However, by August 7 it became apparent that the schedule could be advanced to August 10. When Parsons and Ramsey proposed this change to Tibbets, he expressed regret that the schedule could not be advanced two days instead of only one since good weather was forecast for August 9 and the five succeeding days were expected to be bad. It was finally agreed that Project A would try to be ready for August 9 provided all concerned understood that the advancement of the date by two full days introduced a large measure of uncertainty into the probability of meeting such a drastically revised schedule. However, all went well with the assembly and by 2200 of August 8 the unit was loaded and fully checked.

The strike plane and two observing planes took off at 0347 local time on August 9. Major C. W. Sweeney was pilot of the strike ship,

Captain K. K. Beahan was bombardier, Commander F. L. Ashworth was bomb Commander, and Lt. Philip Barnes was electronics test Officer. This mission was as eventful as the Hiroshima mission was operationally routine.

Due to bad weather between Tinian and Iwo Jima, a preliminary rendezvous was not planned for three aircraft at Iwo Jima, and instead, the briefed route to the Japanese Empire was from Tinian direct to Yakoshima or Kyushu. The briefed cruising altitude was 17,000 feet. Commander Ashworth's log for the trip is as follows:

Commander Ashworth's log:

0347	Take off
0400	Changed green plugs to red prior to pressurizing
0500	Charged detonator condensers to test leakage. Satisfactory.
0900	Arrived rendezvous point at Yakoshima and circled awaiting accompanying aircraft.
0920	One B-29 sighted and joined in formation
0950	Departed from Yakoshima proceeding to primary target Kokura having failed to rendezvous with second B-29. The weather reports received by radio indicated good weather at Kokura (3/10 low clouds, no intermediate or high clouds, and forecast of improving conditions). The weather reports for Nagasaki were good but increasing cloudiness was forecast. For this reason the primary target was selected.

1044 Arrived initial point and started run on target. Target was obscured by heavy ground haze and smoke. Two additional runs were made hoping that the target might be picked up after closer observation. However, at no time was the aiming point seen. It was then decided to proceed to Nagasaki; approximately 45 minutes spent in the primary target area.

1150 Arrived in Nagasaki target area. Approach to target was entirely by radar. At 1158 the bomb was dropped after a twenty second visual bombing run. The bomb functioned normally in all respects.

1205 Departed for Okinawa after having circled smoke column. Lack of available gasoline caused by an inoperative bomb tank booster pump forced decision to land at Okinawa before returning to Tinian.

1351 Landed at Yontan Field, Okinawa

1706 Departed Okinawa for Tinian

2245 Landed at Tinian

Due to bad weather, good photo-reconnaissance pictures were not obtained until almost a week after the Nagasaki mission. These showed that the bomb detonated somewhat north of the Mitsubishi Steel and Arm Works. All other factories and buildings on the Urakami River from the Nakajima Gawa River through the Mitsubishi Urakami Ordnance Plant were destroyed. The distance from the northernmost factory that was destroyed to the southern boundary of

final disposition of Project A property.

6.2 CONCLUSION

Project A, after a long period of preparation in the United States, had a very short but highly intense and successful period of activity overseas. As in all urgently expedited development projects for which there are no precedents, many mistakes were made in Project A. With the benefit of the experience accumulated by Project A it would subsequently be possible to replan its activities to accomplish its objectives both with greater economy and with improved designs. However, despite the novelty of the weapon and the lack of precedent for most of its problems, Project A did successfully accomplish all of its major objectives and did so on or ahead of schedule.

The object of Project A was to assure the successful combat use of an atomic bomb at the earliest possible date after a field test of an atomic explosion and after the availability of the necessary nuclear material. This object was very effectively accomplished. The first combat bomb was ready for use against the enemy within seventeen days after the first experimental nuclear explosion at Alamogordo and almost all of the intervening time was spent in accumulating additional active material for making an additional bomb. The first atomic bomb was prepared for combat use against the enemy on August 2 within four days of the time of the delivery of all the active material needed for that bomb. Actual combat use was delayed until August 6 only by bad weather over Japan. The second atomic bomb was used in combat three days after the first, despite its being a com-

pletely different model and one much more difficult to assemble. The success of the combat use of the atomic bomb is best summarized by the fact that Japan began surrender negotiations four days after the use of the first atomic bomb.

OFFICE MEMORANDUM

[redacted] Los Alamos, New Mexico 87545

Distribution DATE: August 2, 1979

This declassified document shows that no beryllium is used in weapons W25, B28, W31, B33, B53, W53 or B61.

A R. D. Baker, ADW

JECT THE LASL POSITION ON FUTURE AVAILABILITY OF BERYLLIUM AND BERYLLIUM OXIDE (U)

SOL ADNSP

STOP 100

The past nine months or so have presented a somewhat perturbing problem for us with respect to the use of beryllium and beryllium oxide in our weapon designs. The variety of opinions and views expressed may have enough of us confused to warrant an explanation of what I believe to be our current position.

The Occupational Safety and Health Administration (OSHA) of the United States Department of Labor (DOL) published, on October 17, 1975, in 40 Federal Register 48814, a "Proposed Occupational Safety and Health Standard for Exposure to Beryllium", which drastically reduced the amount of beryllium products permitted in the air in the workplaces throughout the beryllium industry. This proposed standard was amended twice and was then submitted to the public for comments.

Neither the Department of Energy (DOE) nor the Department of Defense (DOD) was represented at the public hearings on the proposed standard, which were held in Washington in August and September of 1977. The primary beryllium industry was represented, and the difficulties of meeting the proposed standard were pointed out somewhat ineffectively. Briefly, the industry claimed they would be unable to continue production of beryllium (Be) metal and, perhaps, beryllium oxide (BeO). This point was later brought out more emphatically in the press and other media.

In January 1978, the Albuquerque Operations Office (ALO) of the Office of Military Application (MA) of DOE formed a Beryllium Task Group to define the impact of the proposed standard on the Be industry, and to evaluate options available to DOE to minimize the effects of the proposed

CONFIDENTIAL

standard. Both KBI and BWI repeatedly informed the DOE/ALO Beryllium Task Group that they cannot meet the proposed new OSHA standard, regardless of how much time, effort, and money they spend; this appears to be questionable. However, even if the industry believed they could meet or closely approach the standard, the small volume of Be metal business does not warrant their investing the necessary amounts of money in new equipment to attempt to meet it. Hence, any such activities would probably require government funding. We now understand that KBI is going to get out of the Be metal business, leaving BWI as the sole source (and in the driver's seat as they pointed out to OMA).

Further he suggests that the government should support research and development programs to find new, nonhazardous, or less-hazardous, processing techniques to produce Be and BeO from the beryllium hydroxide ($Be(OH)_2$) currently produced from the ores by BWI at their Delta, Utah mill. Instituting such techniques in the industry as soon as possible clearly would be a major step toward meeting the proposed standard in the primary beryllium industry, or toward improving the workplace environment even if the standard is not promulgated.

In view of the foregoing, it was deemed worthwhile to state the LASL position on the future availability and uses of Be and BeO. That position follows:

It does not appear that preserving the availability of either beryllium metal (Be) or beryllium oxide (BeO) is mandatory to the Department of Energy (DOE) for the long term, although such preservation may be desirable if it can be achieved by reasonable expenditures of both effort and money. Preserving this availability may well be mandatory, for the short term, to complete production of such current weapons and systems as do utilize these materials, where redesign and testing are impractical.

LASL presently has six weapon types in stockpile (W25, B28, W31, B33, B53, W53) and two entering production (B61-3, B61-4) that contain neither Be nor BeO. We had offered to provide a redesigned W80 without these

materials, pointing out that a complete modification of the production schedule would be required if this option were to to be exercised. We believe that a variation on the W76 could also be provided without these materials. Changes of this nature would require full-scale testing and additional development and production funding. We have informed DOE of such other penalties as might possibly be incurred by eliminating Be and BeO, e.g., possible lower yields, possible greater use of Special Nuclear Materials (SNM), possible greater weight, and probable additional nuclear tests.

Because the Be and BeO availability is uncertain and may remain so for months or even years of hearings and of litigation, we believe that it is extremely important that the nuclear design laboratories design future weapons to use either a minimum of, or no Be and BeO. The DOE/ALO Beryllium Task Group was informed that this is the position of the British Ministry of Defense (MOD). Also, the U. S. Air Force-sponsored Joint Aeronautical Materials Activity Committee (JAMAC) has officially notified Space and Missile Systems Organization (SAMSO) of the Air Force that: "... If beryllium substitutes are available or contemplated, it is strongly urged that their implementation be sought as soon as possible. Unless absolutely necessary, beryllium usage should be avoided in all new systems."

Consistent with the above outlined position, we are working with the Integrated Contractors and within our own materials development organization to perfect and test substitute and alternate materials for the Be and BeO applications in all of our contemplated weapons systems.

We also believe that such beryllium as is determined to be "absolutely necessary" for optimal weapon performance should be ingot-sheet beryllium wherever feasible. The ingot-sheet facility at Rocky Flats could be reconstituted and expanded as necessary, and the design laboratories should attempt to use this material in preference to powder-metallurgy beryllium. There is a substantial quantity of beryllium scrap presently on hand in the DOE complex which could be recycled through Rocky Flats.

JANUARY 15, 1945

Further assemblies of UH_{10} using U and WC tampers have been made by Group G-1. Criticality has been reached now in BeO, U, and WC and it is found that the observed results are considerably higher than those calculated. The results which for the case of U and WC must be decreased slightly for the effect of the extraneous material on the assembly are as follows: BeO predicted 2.1 kg 25, observed 3.2; U predicted 3.8, observed 6.8; WC predicted 5.1, observed 7.5. A further observation on BeO gave a 5.5 kg of 25 as critical mass when the core was surrounded by Cd. The disagreement between experimental and theoretical results indicates that our understanding of the hydride is far from complete.

In the course of these critical mass experiments, some difficulty was encountered due to changing experimental conditions when additional material was added. Introduction of detecting chambers near the core caused asymmetries which made the effect of added material depend in a rather pronounced way upon its position. Some experience was also obtained with extrapolations to the critical mass using external Geiger counters and internal fission chamber and external long counters. It was found that a fairly good prediction could be made when a long counter was used externally. It seems to be important to eliminate as much extraneous material as possible from the internal assembly. It is, of course, difficult to make measurements with an external detector, and for this

Early 1945	Initial consideration of weapon.
8/2/45	Z Division of the Los Alamos Laboratory organized - Mk 4 development started.
9/27/45	Z-Division representatives started move to Sandia Base.
9/28/45	Issuance of Z-Division progress reports begun.
10/4/45	Mk 4 schedule defined.
12/14/45	Initial practice drop made at the Los Lunas Bombing Range.
7/46	Operation Crossroads at Bikini Atoll - Mk 4 development interrupted.
8/1/46	Atomic Energy Act passed.
2/47	Z Division consolidated at Sandia Base.
4/4/47	First half-scale Mk 4 drops conducted at Salton Sea Test Base.
3/2/48	Sandia Research and Development Board organized.
4/1/48	Z Division becomes Sandia Branch, Los Alamos Scientific Laboratory.
Mid-1948	Operation Sandstone at the Eniwetok Atoll - Mk 4 development delayed.
1/15/49	Mk 4 Preliminary Evaluation Report issued.
3/19/49	Mk 4 weapon enters stockpile.

Chapter I - The Design Task

The Mk 4 weapon was the first atomic bomb to be designed as a practical piece of ordnance as contrasted to a laboratory device that would function properly only when assembled and used by highly trained personnel under closely controlled conditions. The initial approach to this bomb was made early in 1945, shortly after the wartime ordnance designs were frozen. At this time, the implosion-type weapon (which had been initially called the 1561 after its Los Alamos drawing number) had been code-named the Fat Man in recognition of its outer shape, which possessed a distinct midriff bulge. Various designs of the Fat Man were subsequently assigned Mark nomenclature, but there is some question as to the precise definition of either the Mk I or the Mk II designs. The version of the Fat Man that was manufactured and stockpiled after the end of the War (to the basic wartime design) was called the Mk III.[1]

There were several reasons why it was necessary to redesign the Mk III. In addition to the desire to create a practical piece of ordnance--one that could be used in combat by a military team of average training and capabilities--it was hoped to develop better manufacturing and assembly techniques and to clean up marginal ballistic and vibration characteristics, in the interests of improving bombing accuracy. The weapon that eventually evolved from these redesign efforts was for a time called the Mk IV Fat Man, but toward the end of the program the Roman numeral was replaced by the Arabic number 4, and herein we will generally refer to the weapon as the Mk 4.

Initially, consideration was given to design and manufacture of various ballistic or external shapes, investigation of internal pressures within the high-explosive sphere, redesign of detonators for easy installation,

and the proper number of high-explosive lenses for efficient implosion. These studies, at first carried out in different parts of the Los Alamos Laboratory, were consolidated in one organization August 2, 1945, when the Z Division of the Laboratory was created to carry on activities of ordnance design and delivery of atomic bombs. Jerrold Zacharias, who had been active in the radar group of the Massachusetts Institute of Technology Radiation Laboratory, was selected to head this new organization, the Z nomenclature stemming from the first letter of his last name.

The broad area of responsibility of the new Division was indicated in a memorandum dated August 6, 1945, from Dr. Zacharias to J. Robert Oppenheimer, Director of the Los Alamos Laboratory. In part, the memorandum read:

> "With the organization of Z Division in such a fluid state, it is tempting to put nothing on paper. The Division is likely to become larger and to take on so many duties of so many different divisions that a more vertical organization than is usual in Project Y [Los Alamos] will have to be sought."

Dr. Zacharias then proposed an organizational breakdown of the Division, with work assignments as follows:

Z-1, Experimental Systems Engineering, to perform airborne testing, ballistics, aerodynamics, radar, and informer or telemetering work.

Z-2, Assembly Factory and Procurement, to procure, assemble, and ship weapons.

Z-3, Electrical Engineering, to design firing circuits and detonators.

Z-4, Mechanical Engineering for Production, to be concerned with general engineering changes, and--most pertinent to this history--the "coordination of development of streamlined gadget" (i.e., the Mk 4).

Z-5, Electronic Engineering, to handle fuze development.

Chapter II - Early Development

It now became necessary to provide adequate space and facilities for the work of the Z Division. The first step in this direction was taken in the fall of 1945, when the Engineering Division of Los Alamos was requested to design a testing laboratory. This laboratory would simulate on the ground the conditions which bombs and components experienced in flight. This testing laboratory was subsequently built and proved of material assistance in the development of the new weapon.

Meanwhile, a proper work location for the assembly group, Z-2, was being discussed. This organization, which was largely staffed with military and Civil Service personnel, could be administratively separated from the rest of the Division, and required an area convenient to air and rail transportation. A logical spot was the former Oxnard Field, the original Albuquerque Airport (now called Sandia Base), which already was the property of the Manhattan Engineer District, having been obtained in July 1945 for the never-consummated objective of providing space for temporary storage of atomic-bomb materiel during World War II. A meeting was held at Sandia August 29, 1945, at which time it was decided to transfer Z-2 to Sandia Base. It was also decided to remove the W-47 Flight Test Group from Wendover Field, Utah, and bring some of these personnel to Sandia Base.[4] After further discussion, it was decided that weapons production and test activities would be concentrated at Sandia and design work at Los Alamos.[5]

The first Z-Division representatives moved from Los Alamos to Sandia Base September 27, 1945, and on the following day Dr. Zacharias inaugurated the practice of issuing monthly progress reports.[6] The initial report of the Mechanical Engineering Group, Z-4, noted that work on the Fat Man was directed toward making this bomb a more reliable and serviceable weapon--more of a re-engineering task than a radical redesign of the entire gadget.

("Gadget" was a common term in those days for an atomic device.) The report pointed out that the Mk III had to be assembled component by component, while it was hoped that the new bomb could be put together in fairly large subassemblies. In line with this objective, a start had been made in consolidating some of the electrical items into a "cartridge" that could be inserted into the weapon as a unit (in the same manner that a cartridge was inserted in the chamber of a rifle).

A conference between military and Z-Division personnel had meanwhile been held at Wright Field, Ohio, September 21, 1945, to review aircraft capable of carrying the proposed bomb. The B-36 long-range bomber was in the last phases of design and was nearing the flight-test stage, and several jet-propelled medium bombers were being developed. However, the B-36 had a relatively low top speed, and the jet bombers (at that time) were restricted in range, so it was concluded that any immediate redesign of the Fat Man must, of necessity, keep the B-29 in mind as the delivery vehicle.[7]

A Mk 4 planning meeting was held October 4, 1945, at which an optimistic schedule was laid out. The coefficient of expansion of the high-explosive sphere was to be determined by November 1, 1945. The external shape of the bomb and the elements of the firing circuitry were to be settled by December 1, and the sphere assembly and mounting were to be designed by December 15. Drawings of the tail, the cartridge, and the electrical equipment were to be prepared by January 1, 1946. Handling equipment was to be available by February 1; full-scale drops were to be started March 15; a pit and sphere assembly was to be completed by May 15; and the entire bomb was to be ready for stockpile production, with all problems solved, by July 1, 1946. (b)(3)

It is obvious ... that the

estimated date of July 1 for the completed bomb is contingent on the progress made with the pit."[6] However, it was understood that, should the nuclear design be produced, the weapons hardware group was to be ready with the rest of the bomb, and the Z Division swung into high gear.

During design of the wartime Fat Man, there had not been enough time to make a thorough analysis of component functions and their relationships to the overall weapon system. A study was thus started, covering the circuit elements of the bomb and the part played by such factors as simultaneity of switch operation in overall efficiency. Ballistic problems, further described in Chapter III, also were examined. To meet this need, a field-test range was secured, arrangements made for wind-tunnel work, and special telemetry apparatus started into design.

Improvements were made to various elements of the firing system, notably the X-unit, which created the high-voltage surge of current that fired the weapon detonators. The wartime implosion bomb had been equipped with an X-unit whose capacitors were charged to approximately 5600 volts before the bomb was released from the carrying airplane. This not only created a hazard to the bomber crew, but made it necessary to pressurize the X-unit to prevent internal arcing at bomb release altitudes. A safer and simpler X-unit was designed, which was charged after the bomb had fallen to its fuzing altitude, a safe distance from the strike aircraft.

Detonators were modified for easier installation, and much attention was paid to the design of segment molds and the lenses for most efficient implosion of the high-explosive sphere. Extensive tests were made of face pressures between high-explosive segments, and studies were conducted of improved systems of detonator cabling. The protruding Mk III (Yagi) antennas were redesigned to be recessed into the flattened nose of the

bomb, thus simplifying weapon handling. So-called "Dipsy-Doodle" flight tests were conducted to determine the effects of signal interruption on the fuzing and firing system, and minor improvements were made to radar units and to the clock box circuits.[6]

The entire Division compiled lists of needed personnel and prepared plans for anticipated space at Sandia and Los Alamos. Many Division members were military representatives of the Special Engineer Detachment of the Manhattan Engineer District that had been formed to assist Los Alamos scientific personnel during the war, and efforts were made to interest these people in transferring to the Z Division in a civilian capacity.

This acceleration of effort continued for several months, only to be slowed down (in the design area) by many circumstances. One of these was Operation Crossroads, the first postwar full-scale test of atomic bombs. This operation took place at Bikini in July 1946, and many people from the Z Division were assigned in the early months of the year to help with the work. A second factor was loss of supervisory personnel. As an example, Dr. Zacharias returned to the Massachusetts Institute of Technology on September 28, 1945 (to be succeeded by Roger S. Warner, Jr., previously in charge of Z-2B, "Production Schedules and Manuals").[6] This was the first of many such moves, as in the next 15 months, 8 out of 10 Z-Division supervisors were to leave and be similarly replaced. A third item was the loss of trained military personnel as postwar demobilization got under way in early 1946 and career officers were returned to prewar commands. Finally, the lack of specific directives for new bomb design and production, and the general dearth of needed facilities impaired the progress of the overall work.

When the Crossroads contingent returned to the Division in the late summer of 1946, work on the Mk 4 was resumed, although at a somewhat slower pace. The Crossroads test had included an atomic device detonated under water, and the success of this explosion against target ships resulted in a demand for a penetrating weapon. The work on this latter device resulted in manpower being diverted from the Mk 4 program.

The passage of the Atomic Energy Act, August 1, 1946, resulted in cancellation by the Military of plans for Sandia buildings and facilities. The newly created Atomic Energy Commission could not immediately act to counter this cancellation, and securing needed space for the Mk 4 effort was delayed. Supply problems were aggravated as a result of the physical separation of parts of the Division from Los Alamos, with the Z-Division Progress Report of October 1946 noting that daily operations were "continually hampered by an inadequate supply of the common every-day types of electrical equipment ... such things as ordinary rosin solder, hook-up wire, etc."[6]

The need for this new weapon was, however, becoming more apparent, with the Division Leader reporting on November 29, 1946: "As we reach the end of the 1561 FM stockpiling program ... we are finding more and more subassemblies which are marginal .... In certain cases where we have taken steps to bolster one weakness, another develops, and so on ad nauseam until we reach the stage where by physical handling and reworking the component is worn out before it reaches the stockpile .... Because of the low confidence I have in the 1561 gadget, I request the Tech Board to permit me to carry through with the Mk IV test program under forced draft."[8]

Consequently, by early 1947, work was again moving forward and progress could be noted.[9] A full-size Mk 4 prototype shape was built and used in the design of handling equipment. The Z-4 group was moved from Los Alamos to Sandia Base, thus consolidating the entire Division at one location.

Mr. Warner became the AEC's first Director of Engineering and was replaced as head of the Z Division by Robert W. Henderson of Z-4. The Armed Forces Special Weapons Project was created to handle military functions relating to atomic energy, with an office being established on Sandia Base to provide liaison with the Z Division.

A date of March 15, 1948, was agreed to at a meeting of Z-Division supervisors on April 16, 1947, for a "proven Mk IV bomb ready to be procured in quantity by Road." (Road was a general code term for production and stockpiling activities, as the fact that the Division was producing atomic weapons was highly classified.) The meeting report also noted: "A tremendous responsibility has been given to Z Division to have this bomb by the above deadline because either the Mark IV is ready by that date or all work must cease and a new project along different lines must begin." (Official recognition was thus taken of approaching new weapons programs.) All groups were requested to determine their manpower needs and to make a realistic estimate of any additional personnel required, "realizing that even after the people have been found, a 45-day delay for clearance will follow."[10]

New employees subsequently were added to the Division. The cartridge design was completed and started into production. A thorough study was made of the proper location of detonator cabling. The sphere design was completed, and the assembly of the sphere to the outer case was checked out. Investigation was made of barometric switch operation, including the proper location of external ports in the outer case to provide pressure sensing as the bomb fell toward the target. It became necessary to seal the outer case to control this pressure sensing, and different sealing methods were proposed and tested. Handling equipment and storage containers were designed and built.

specifications, was issued January 15, 1949. A crash program produced test and handling equipment for military training and for possible emergency use.[20] As a result of this intensive effort, the first Mk 4 Bomb entered stockpile March 19, 1949.[21]

Field; and to confer with aerodynamicists and ballistics experts. They were informed that the best tail was a design using four equally spaced airfoils, and that these airfoils had to extend some distance out from the body of the bomb since, at high velocities, the air flow broke away from the bomb contour at approximately the maximum diameter of the bomb. It was felt unwise to permit the velocity of the bomb to exceed Mach 1 (the speed of sound), due to buildup of vibration, and it was suggested that a tail shroud be used to retard the rate of fall of the bomb if this velocity was approached in full-scale drops. The use of a blunt rather than a round nose was recommended in an effort to further retard the rate of fall.

A wind-tunnel test program was outlined, to be conducted at Aberdeen. Body shapes without tails would be initially investigated, and the best shapes fitted with simple fins and tested further. If these designs were not completely stable, a circular tail shroud would be added. These wind-tunnel tests would be made at speeds expected to be encountered in actual drops, and stability of the bomb shapes at higher or supersonic speeds would be checked by firing 20-millimeter-diameter models from a gun. It was felt that little could be done to improve the body of the bomb, due to the dimensional limitations imposed by high-explosive sphere and bomb bay, and that efforts should be concentrated on tail modifications.[22]

It had been decided to start full-scale test drops as soon as possible, and an aerial survey of World War II practice ranges in the vicinity of Albuquerque was made September 19, 1945, by members of Z-1. As a result, Range S-1 (which was renamed the Los Lunas Range) was selected for use. This range was located west of the town of Los Lunas and approximately 25 miles southwest of Albuquerque.[23]

In preparation for the work at Los Lunas, recording and communications gear was installed in trailers which could be based at Albuquerque and

less yaw in flight than the standard fin. Fairly consistent performance was also obtained using a thin fin (with a plan area decreased approximately 25 percent) and a circular shroud. Neither of these two types, however, gave completely satisfactory ballistic performance.[27]

Members of the Armed Forces Special Weapons Project suggested that a group of aerodynamicists might be able to suggest improvements in ballistic characteristics, inasmuch as a great deal had recently been learned concerning actions of bodies passing through the transonic region, which had been pierced by manned aircraft only a few months previously. Consequently, representatives of Northrop, Rand, Douglas, North American, Boeing, Wright-Patterson Air Force Base, Inyokern, and Aberdeen formed an advisory panel which initially met May 26 and 27, 1948. The panel suggested that thin fins with flat sides and wedge cross sections would perform better than fins with curved sides and airfoil cross sections. It was also proposed that the planform of the fin be enlarged and drag introduced by the use of plates or spoilers to hold the velocity of the bomb below the transonic range. Arrangements were made to use the Cooperative Wind Tunnel at the California Institute of Technology, which had a greater velocity range than the Aberdeen tunnel.[28]

The flat-sided wedge fins were subsequently tested at the Cooperative Wind Tunnel and exhibited good stability.[22] Consistently good results were obtained from drop tests and, in mid-September 1948, the large-plan wedge fin was tentatively selected for use.[29,30] Detailed results of tests at the Cooperative Wind Tunnel became available October 1, 1948, and confirmed the results noted above. Perforated tail plates were tested on two bombs; one with a square plate and the other circular. The first gave improved control over pitch and yaw, while the second resulted in decreased control--hardly a conclusive test.

Since there was now a limited amount of time and drop tests that could be made, it was decided to concentrate on trials of a large-plan wedge, a thin-fin shroud wedge, a dorsal wedge, and a large plan with a sloping leading edge. All these, it was felt, would have about the same ballistic characteristics. A closer examination of wind-tunnel data subsequently narrowed the choice to a large-plan wedge or a thin-fin shroud wedge. It was then found that the reliability of the thin-fin shroud declined in high-speed, high-altitude drops, whereas the large-plan wedge did not, and the latter design became the obvious choice.

Aberdeen wartime experience with certain experimental bombs had indicated that a "flap" placed at the rear of a bomb shroud (which presented a greater angle of attack to the approaching air than the fin) would help to stabilize bomb flight, and large-plan wedge and thin-fin shroud tails were prepared with this modification. The first to be dropped was the large-plan wedge. One drop showed such excellent flight characteristics--with pitch and yaw of only about 2-1/2 degrees and a ballistic velocity coefficient only slightly lower than that of the thin-fin shroud--that it was deemed advisable to concentrate on further drops of this type, rather than expending time and energy on the thin-fin shroud, which was difficult to fabricate.[22] Accordingly, the large-plan wedge design was frozen for Road production in December 1948.

(b)(1), (b)(3)

More intensive testing in mid-1950 revealed that bomb instability could occur when the Mk 4 was released at altitudes of 26,000 to 31,000 feet, and it was recommended that releases be made above or below this range.[32] It was theorized that this instability was caused by the development of a large shock wave near the fins and the use of circumferential spoiler bands to create smaller shock waves at the mid-point of the bomb and prevent formation of this one large shock wave, was suggested.[33] Tests subsequently made in the Wright Field wind tunnel showed that the Mk 4 shape with five of these spoiler bands possessed good stability.[34] These wind-tunnel tests were the last performed on the Mk 4 weapon, as it was felt more logical to apply the spoiler bands to the approaching Mk 6 Bomb rather than to retrofit them to the Mk 4.[35] As a result, all ballistic testing on the Mk 4 Bomb came to an end.

case. The center "belly band" section was split at the top so that it could be spread apart with assembly tools and slipped over the sphere flanges for positioning over the center section of the sphere. Tension bolts pulled the split-band together at the top. A large rubber gasket sealed the surfaces where the steel case met the aluminum sphere case. The forward case supported the antenna nose plate, which could be removed for access to the sphere. The inflight insertion gear was supported by the forward case. The four fins, which were of aluminum sheet-metal construction, were bolted to the rear case.

(b)(3)

The cartridge structure supported the fuzing components, was cylindrical in shape, and used riveted aluminum sheet-metal construction. The X-unit was bolted to the forward end of this assembly, and the entire unit was

fastened to the bomb sphere case by bolts through the X-unit flange. Shelves and mounting plates were provided in the cartridge structure for installation of fuzing components.

The fuzing and firing system contained the same general components used in the Mk III Mods 1 and 2, but were mounted in a single cartridge structure. The X-unit used the same basic electrical design as that of the Mk III, but was redesigned to reduce size and weight, and to adapt it to the cartridge structure.

The four radar antennas had cavity-backed slot designs and were mounted on a nose plate at the front of the bomb. Being flush with the outer surface of the weapon, these were superior from the aerodynamic and handling standpoints to the Yagi-type antenna used on the Little Boy and Mk III Bombs.

The clock timers and batteries were provided with heated, insulated covers to protect against freezing during flight to the target. These heaters were powered from the aircraft electrical system through a cable connection at the upper surface of the rear case which was separated when the bomb dropped away from the aircraft. This same pullout cable was used during flight to monitor the electrical components in the bomb.

The "Archie" radars were modified APS-13 "Tail Warning Charlie" radars developed during World War II. They were adapted to the bomb fuzing application by using a different antenna system and modifying the range gate. (b)(3)

The early radars required alteration by soldering iron to change the range setting, but later modifications provided plug-in gate lines.

(b)(3)

(b)(1), (b)(3)

The following aircraft were equipped to deliver the Mk 4. For the Air Force; B-29, B-36D, B-36F, B-47B, B-50A, and B-50D. For the Navy; AJ1 and AJ2. Since the Mk 4 was originally designed for carriage by B-29 and similar land-based aircraft, no provision had been made for resisting catapult loads. With the development of Navy aircraft capable of taking off with the bomb from the deck of an aircraft carrier, some difficulty at the sway-brace locations was encountered. This was overcome by redesigning the sway braces in the aircraft bomb bay so as to distribute the load over a sufficient area to prevent damage to the outer case of the Mk 4.

The Mk 4 Mod 0 Bomb entered stockpile March 1949. It was not equipped for inflight nuclear insertion. It included the Type C pit and had an inflatable rubber gasket to seal the ballistic case. Baro ports were located at the nose of the bomb, and the entire interior of the bomb case was used as a "plenum chamber" to provide static pressure to the baroswitches.

The "Mod-Alt" change system was not in use at this time, and major changes were processed under a "block" change system. All weapons in a given "block" of units incorporated the same changes. In May 1950 the Mk-Mod-Alt weapon designation system was instituted, and the weapon was divided into three major assemblies, bomb, fuze, and capsule.[42] The bomb capable of inflight nuclear insertion became the Mk 4 Mod 1

(previously identified as the Block 7 weapon). It also included a solid rubber gasket for sealing the ballistic case. Since it had a Type C pit, the complete bomb nomenclature was Mk 4 Mod 1-C.

The Mk 4 Mod 2-C Bomb incorporated a baro manifold, which was a circular copper tubing assembly installed in the rear ballistic case.[43] Static pressure was provided from intake ports in the rear cover plate through flexible hose leading to the manifold and additional flexible hose connected the manifold to the baroswitches. The accuracy of the baro system was improved by this change, since it no longer depended on a sealed ballistic case for a static pressure source.

The Mk 4 Mod 2-D Bomb incorporated a Type D pit with a higher yield.[44] Special handling equipment was required for insertion of this capsule into the pit, and included a loading tool and a capsule alignment tool or loading trough. By the end of 1951, all Mk 4's had been retrofitted to the Type D pit.[45]

The Mk 4 Mod 3 Bomb incorporated a lightweight magnesium antenna nose plate for easy manual handling. This permitted simplification of the inflight nuclear insertion gear and speeded the operation. Since this change was incorporated on bombs having either the Type C or D pit, it was identified as the Mod 3-C or Mod 3-D.

The "cartridge" became, under the new system, the Mk 4 Mod 1 Fuze. This included the AR-10A "Archie" radars (four required), BS-4 or BS-5 Baroswitches (six required), M-127 "clock" timers (eight required), Mk 4 X-unit, and lead-acid ER-12-10 batteries. The components were mounted on an aluminum structure for convenient installation (b)(3)

interval before supplying power to the firing set. This time interval allowed the airplane to get beyond radar fuzing range, preventing premature detonation by radars ranging off the aircraft. Closing of the arming switches by the clocks allowed current from the 30-volt battery packs to flow through the X-unit choke and the closed firing switch. This current flow caused a magnetic field to be built up in the choke.

At a predetermined altitude, well above the desired burst height, baroswitches closed, allowing the radars to start transmitting and receiving. At the preset burst height, the ranging of any two of the four radars off the target operated a relay network which opened the firing switch in the X-unit. The rapid opening of this firing switch caused a collapse of the magnetic field in the choke, transferring electrical energy to a condenser. When the voltage in the condenser built up to approximately 4000 volts, the spark-gap switch spontaneously broke down, allowing current to flow through the gap and the detonator circuits.

Bridge wires in the detonators were vaporized by the high-voltage pulse. This detonated the explosive material in the detonators, which in turn ignited the high-explosive charges of the sphere, creating a spherically convergent detonation wave which compressed the nuclear components to supercriticality.

(b)(1), (b)(3)

Chapter V - Mk 4 Improvement

After the Mk 4 entered stockpile, design improvements continued despite the fact that much of the engineering staff was transferred to work on other weapons. A list of desirable modifications was compiled, based on a joint military-Sandia survey, and, after thorough review, was formally issued May 18, 1949, under the title "Desired Military and Technical Characteristics of FM Type Atomic Weapons."[48]

Five areas were listed, including weapon battery, ballistics, inflight nuclear insertion and extraction, lightweight case, and improved fuzing system. Battery improvement, due to the state of the art, was deferred for later consideration; the ballistics story has been developed in Chapter III.

The inflight nuclear insertion and extraction project was already well under way, as studies had started in early 1948, (b)(3)

Facilities for supporting the antenna nose plate and sphere access door while the nuclear capsule was being guided into position were also provided. This support device was temporarily bolted to the nose of the bomb while it was in the bomb bay of the aircraft proceeding to target, and was manually operated.[18] A later production version eliminated the support arms for the nose plate and access door, which by that time had been much reduced in weight.

This topic was mentioned in the September 30, 1948, meeting of the Sandia Research and Development Board, with Sandia pointing out that the change would necessitate a major change in material sources, tooling, and bomb handling equipment, and that a thorough stress analysis would be required.

Subsequently, considerable correspondence on the subject developed between the Division of Military Application, Military Liaison Committee, AEC, and Sandia, with efforts being made to determine whether or not there was a real need for the heavy case for either flak protection or storage.[53,54,55,56] On December 24, 1948, Sandia informed AEC that a development program for reduction of Mk 4 Bomb weight had been established at Project Roger (the Army's Rock Island Arsenal, which was handling certain weapons production work) and its subcontractor, the American Car and Foundry Company. The purpose of this program was to evaluate and recommend weight reductions based on an aluminum outer case produced by the same tools used for forming the steel casing.[57]

Meanwhile, various pressures were exerted both for and against the design of a lightweight case,[58,59,60] with the matter being decided February 17, 1949, when the Division of Military Application directed Sandia to subcontract the design of an aluminum case.[61] On March 16, Northrop Aircraft, Inc., was invited to design a riveted case,[62] and in May the American Car and Foundry Company was asked to design a welded case.

Ballistic testing of both the riveted and welded cases was conducted in December 1949, and static and dynamic tests were run at Wright Field.[63] These proved that both cases were satisfactory, and, inasmuch as cost and weight comparisons were roughly equivalent, it was decided to procure both types.[64,65,66,67] Production of the riveted design was turned over to Project Royal (the AEC manufacturing facility at Kansas City), and the

(b)(1), (b)(3)

Meanwhile, it was becoming evident that the lightweight case and the improved fuze could be put into production simultaneously, and in July 1950 a high-priority or "crash" program called 4-N was established.(b)(3)

Shortly thereafter, however, it was decided to treat the modified Mk 4 as an entirely new weapon, and the program evolved into the Mk 6.

Design attention was also given to improving the pressure-operated or barometric switch which "armed" or placed the radar in operational condition. The original approach had been to consider the interior of the bomb as a plenum or pressure chamber and to measure the pressure as the bomb fell through the air toward the target. Vent holes to the external atmosphere were located in the nose of the bomb, and it became necessary to provide an airtight seal between the sections of the bomb case.

It was at first thought that an inflatable rubber tube would serve for this seal,[74] but it was found impossible to maintain air pressure in this tube. In addition, the relatively large volume of the plenum chamber made it difficult to secure rapid responses to changes in external air density, and it was decided to substitute a small-volume manifold constructed from a length of tubing bent into a circular shape and installed under the contour of the bomb skin near the tail. Because of the possibility of the nose ports becoming plugged with ice,[75] they were relocated in the tail plate.[76]

UNCLASSIFIED

Implosion-Type Bomb -- A weapon based on the principle discovered by Professor Charles E. Munroe, Washington, D. C. Written up by him in Scribner's Magazine and the American Journal of Science in 1888 and in Popular Science Monthly in 1900. Rediscovered by Egon Neuman of Germany, who secured German and English patents in 1910-11. The Munroe principle notes that an increased explosive effect is created when an unconfined cylinder of high explosive is hollowed out. In 1920 the Journal of the Society of Chemical Industry (London) stated that "no practical use has apparently been made of this discovery." Suggested by S. H. Neddermeyer at Los Alamos as a means for producing the extremely high pressures required on the capsule of an atomic bomb. Not much attention was paid to the suggestion until it received the backing of John von Neumann and George Kistiakowsky. The same principle was used in the Pacific area in World War II as a means of destroying Japanese pillboxes, and for increasing the penetrating effect of rockets.

Kiloton Yield -- A means of measuring the effect of a nuclear explosion by comparing it with the effect of an explosion of TNT. One-kiloton yield is equivalent to the effect of 1000 tons of high explosive.

Kirtland Field -- An Air Force Base located in Albuquerque, New Mexico, and using part of the facilities of the Municipal Airport (Sunport). Kirtland Field was built in 1939 with the help of federal funds. Named for Colonel Roy F. Kirtland, one of the earliest Army aviators.

(b)(3)

UNCLASSIFIED

Manhattan Engineer District -- A district of the Army Corps of Engineers established in August 1942 under the command of General Leslie R. Groves to develop weapons using atomic energy.

Military Liaison Committee -- A committee established by the Atomic Energy Act of 1946 to advise and consult with the AEC and on behalf of the Department of Defense, on all atomic-energy matters relating to military applications of atomic weapons. Chairman can be any active or retired officer of the Armed Forces. Includes a representative or representatives from each Department of the Armed Forces.

Operation Crossroads -- See Crossroads.

Operation Greenhouse -- See Greenhouse.

Operation Sandstone -- See Sandstone.

Oxnard Field -- Constructed in 1929 as the airport for the City of Albuquerque by Frank G. Speakman. Named Oxnard Field in 1931 for James G. Oxnard, who financed its expansion and who was its owner until May 1942, when the area was taken over by the Government for an Air Depot Training Station.
(b)(3)

Radars -- See Archies. Named for RAdio Detecting And Ranging.

Salton Sea Test Base -- Located on the site of a Naval Auxiliary Air Station on the shores of Salton Sea, California. Acquired in June 1946 for ballistic tests of the Z Division.

Sandia Base -- Located east of the City of Albuquerque and adjoining Kirtland Field. Encompasses the area formerly occupied by Oxnard Field, plus additional land extending south to the Isleta Indian Reservation and east to the Manzano Mountains. Operated under the tripartite control of the Armed Forces Special Weapons Project.

Sandia Laboratory -- An outgrowth of the Los Alamos Laboratory's Z Division. Originally established as Sandia Branch of LASL; in November 1949 it became an independent entity, Sandia Corporation, with a contract with the AEC and under the managerial direction of the Western Electric Company.

Sandia Research and Development Board -- A joint Sandia Laboratory-military board formed at Sandia Base to provide local guidance on weapons design.

Sandstone -- Full-scale test operation held in the Pacific in April 1948.

Tactical and Technical Liaison Committee -- A committee of Air Force officers established to provide liaison between the atomic project and the Air Force prior to admittance of the Air Force as a member of the Armed Forces Special Weapons Project.

Telemetry -- The science of radio transmission of information to a ground station from an object traveling in space.

Wendover Field -- Located in Utah, west of Salt Lake City. A training location for the Army Air Forces work with wartime atomic bombs.

W-47 Flight Test Group -- The Army Air Forces group stationed at Wendover Field during World War II. Part of this group was transferred to Kirtland Field after the war and helped in the bomb drops at Los Lunas.

Yagi -- A radar antenna developed by a Japanese scientist.

X-Unit -- ~~A high-voltage transformer~~ A device used to provide high voltage to the weapon detonators.

Z Division -- A Los Alamos Laboratory division established in July 1945 to handle development work on atomic bombs. Part of the Z Division was moved to Sandia Base at the close of the war, and became the nucleus of Sandia Laboratory. Named for Jerrold Zacharias, first leader of the Division.

6-1-51	Mk 5 Mod 0 released for production and stockpiling.
11-52	Mk 5 Mod 1 stockpiled.
6-54	Mk 5 Mod 2 stockpiled.
1-55	Mk 5 Mod 3 stockpiled.

HISTORY OF THE MK 5 BOMB

The feasibility of creating a small implosion bomb was one of the weapon concepts studied by the Los Alamos Scientific Laboratory after the end of World War II. The over-all size of the wartime Fat Man device (which was to be as large as possible) had been established by the dimensions of the B-29 bomb bay and the existing state of implosion theory, and the resulting weapon was a bomb with reasonably high nuclear efficiency, but which was difficult to handle due to its bulk and weight (60-inch diameter; 128-inch length; 10,900-pound weight). Consequently, calculations were made of compressions produced by small-diameter high-explosive spheres, and different arrangements of nuclear material were studied.

This small implosion design was of interest to the Military, and the Military Liaison Committee informed the Atomic Energy Commission October 31, 1947, that current implosion bombs did not lend themselves to wide or flexible employment, and that a weapon both lighter and smaller than the Mk 4 (then in design) would be of considerable military importance.[1] The Atomic Energy Commission, in replying to this letter on December 10, 1947, pledged support of a vigorous program to develop a small bomb.[2]

Meanwhile the Division of Military Application wrote to Santa Fe Operations Office November 25, 1947, noting that any reduction in bomb weight would result in an increased range of the carrying aircraft and pointed out that: "Reduced dimensions might open up an entire new field of flexibility in the employment which could be a decisive influence in the military capability of getting the bombs home in war." However, it was noted that the Los Alamos effort on Operation Sandstone (to be held in the Pacific during the summer of 1948 to test new nuclear designs) might delay starting work on the new weapon.[3]

During 1948, it became apparent that determination of size, shape and weight for the lighter and smaller weapon required an understanding of military aircraft, delivery plans and problems. A conference was consequently held at Los Alamos September 2 and 3, 1948, which was attended by representatives of the Military, AEC weapon laboratories, and cleared members of the aircraft industry. It was decided that a bomb with a diameter of 40 to 48 inches and weighing between 5000 and 6000 pounds would cause significant improvement in aircraft performance and increase the probability of successful weapon delivery. It was felt that the length of the weapon should be retained at 128 inches.[4]

(b)(1), (b)(3)

During the foregoing study period, the project had been known as the Small Weapon Program and was directed by the Los Alamos Committee for Weapon Development. It was subsequently transferred, October 11, 1948, to the W (Weapon Development) Division of Los Alamos with the request that this Division undertake an "experimental, calculational, and fabrication program aimed at the production of a specific model of a complete small weapon for test early in 1951."[6]

(b)(1), (b)(3)

The work of the W Division almost immediately involved the Sandia Branch of the Los Alamos Scientific Laboratory and, it was suggested that a Steering Committee be established to direct development work on the weapon.[7] This new group initially met November 3, 1948, and the Chairman noted that much confusion had previously arisen due to various terms used to identify a given weapon, and suggested that a standard weapon name as well as a designation for the Steering Committee be established.[8] Mk IV nomenclature had already been assigned, so it was logical to use the next number, Mk V, for this device. The Committee felt, however, that development models of the weapon should be specifically identified, and it was decided to use the letter "X" as a prefix to show the experimental nature of the design. It was also decided to add the letter "T" to indicate--in the phraseology of the Committee's minutes--"the word 'tentative' or 'tiny' (or something)." Thus the weapon became known as TX-V (and, soon thereafter, the TX-5) and the Committee as the TX-5 Steering Committee. The adoption of this system set the pattern for many subsequent atomic devices.[9]

(b)(1), (b)(3)

(b)(1), (b)(3)

The possibilities of contact or even subsurface burst requirements were briefly considered, but it was felt that the basic design of an implosion weapon made anything but air burst impossible.

(b)(1), (b)(3)

Computer time was scheduled, and it was hoped to have compression figures in about 3 months.[10] (Subsequently, due to the pressure of other computer programs, it was decided to interpolate, using other computational results.) The Steering Committee established a schedule calling for preliminary design by January 1, 1950, and complete design July 1, 1950. (b)(3)

The contents of a December 10, 1948, letter from the AEC General Advisory Committee were discussed in the January 7, 1949, meeting of the TX-5 Steering Committee. This letter stated that reduction of size and weight of atomic weapons was vitally important to national defense and that the AEC wholeheartedly supported the aims of the Steering Committee in this regard. The Advisory Committee hoped that the new small weapon could be ready for production soon after proof-firing, and suggested that a substantial portion of the implosion stockpile in early 1950 be made up of the new bomb. The program was accordingly accelerated.[12]

Problems of nuclear safing had meanwhile been studied. The Sandia Research and Development Board (later renamed Sandia Weapons Development Board and, still later, Special Weapons Development Board) was a group including representatives from Sandia and the Armed Forces Special Weapons Project, the military organization formed to handle military problems connected with the atomic bomb. The Board held an initial meeting March 2, 1948, and suggested that design attention be paid to the possibility of extracting

the nuclear capsule of an atomic bomb while it was being carried to the target. This action would prevent nuclear detonations caused by a landing accident, should the mission be aborted or the plane return to base with weapon unexpended.[13]

The Tactical and Technical Liaison Committee, established by the Air Force to provide atomic liaison, had suggested, March 26, 1948, that both extraction and insertion in flight would increase aircraft and airport safety, and reduce nuclear contamination caused by accidents during takeoffs or landings.[14] (b)(3)

(b)(1), (b)(3)

(b)(3)

The next step was to design some type of capsule handling device, and this became known as an inflight insertion mechanism. The device initially was manually operated, but this operation was awkward due to lack of room in the bomb bay, and the fact that the aircraft had to fly at low altitudes during insertion or extraction. (The bomb bay was not pressurized, and personnel operating the equipment would have been handicapped if required to wear oxygen masks.) An automatic and remotely controlled mechanism was accordingly designed.

Consideration was given to the necessity for duplicate bridge wires in each detonator. (b)(1), (b)(3)

The use of single bridge wires was then proposed, with two X-units connected in parallel to each bridge wire. This raised the question as to whether one X-unit would fire back through the other, rather than across the bridge wires, and it was eventually decided to provide one highly reliable X-unit and to use single bridge wires.

Initial Sandia mention of the new weapon was made in a progress report of February 18, 1949, wherein it was noted that SLE-7 had been organized as the FM Mk V Division.[18] This Division, in starting design work, was confronted with the general shortage of office and engineering space and facilities at Sandia, caused by the concurrent startup or expansion of other design projects.

Selection of aircraft to carry the TX-5 was discussed in the Steering Committee meeting April 8, 1949. The Air Force program was currently slanted toward use of heavy, long-range bombardment aircraft. Medium-size Navy bombers were still under design, and would not be in production for at least 2 years. Consequently, there was some feeling that current schedules might produce a new bomb before a suitable bomber became available.[19]

As a result of the above meeting, a TX-5 Ad Hoc Panel was appointed by the Military Lisison Committee May 12, 1949.[20] (b)(1), (b)(3)

It was agreed that as small a diameter as practicable should be selected, since it would be relatively

"The TX-5 project is one of the weapon developments in which the interest of the Atomic Energy Commission reflects a general concern that within the next few years the problem of successful delivery of atomic weapons may come to overshadow the problem of increasing the destructive potential of the weapons themselves. The Commission recognizes the primary responsibility of the using forces to set forth desired technical characteristics of weapons, as these characteristics bear on the delivery problem. The Commission remains anxious, however, that its best technical effort be contributed to a solution of this problem in all of its variants which impinge in the area of the Commission's responsibility. The Commission will therefore continue to keep you fully informed of prospective reductions in weapon size and weight, hoping that full advantage will be taken of these forecasts to ease the problems of development of future carriers, a field in which the development cycle is of course substantially longer than the usual cycle of development of the associated weapons."[22]

The Military Liaison Committee wrote to the Division of Military Application February 9, 1950, noting their belief that large-implosion-bomb performance could be considerably improved through use of nuclear design improvements produced by the TX-5 work, and stating that the smaller bomb should be reserved for use in guided missiles. The Committee proposed that a decision on TX-5 production be made after the 1951 tests, and stated that it appeared inadvisable at this time to freeze design on a production TX-5 or to plan for any substantial stockpiling.[23] The Division of Military Application stated, in a reply dated March 30, 1950, that the TX-5 nuclear design improvements might obviate any need for larger bombs, but agreed that higher priority would be assigned to use of the TX-5 with future guided missiles.[24]

The cumulative effect of the above correspondence might have redirected the TX-5 program, if the international situation had not intervened. The increasing pressures of the cold war and eventual outbreak of the Korean conflict caused an acceleration of national defense plans and programs, and resulted in a May 10, 1950, visit to Los Alamos by the Director of the Division of Military Application. This visit was discussed in the May 26, 1950, meeting of the TX-5 Steering Committee, in which it was noted that it would be necessary to "pick up a few months or even a year" in TX-5 production.[25] Subsequently, a teletype was received July 11, 1950, from Washington AEC which, in part, stated: "Anticipating a Military requirement not yet firm you are directed to formulate a plan using all facilities at your disposal to deliver to War Reserve at the earliest possible date service models of TX-5."[26]

The schedule that Sandia subsequently prepared established a target date of January 1, 1952, for Mk 5 production. Quantity requirements were authorized in a Military Liaison Committee directive of September 14, 1950, and these figures were revised upward December 18. The Atomic Energy Commission urged all possible speed and noted that:

> "Certain procedures may be warranted at this time that would otherwise not be undertaken until the weapon characteristics were more completely defined. There is an obligation on us all to economize in both effort and money by identifying promptly the areas of uncertainty and pressing for their resolution. There is an equal obligation, however, to take action as necessary to maintain the best possible schedule, even at the risk of occasionally involving ourselves in unproductive ventures."[27]

Figure 2. Comparison of Shape of Mks III and 4

and the proper number of high-explosive lenses for efficient implosion. These studies, at first carried out in different parts of the Los Alamos Laboratory, were consolidated in one organization August 2, 1945, when the Z Division of the Laboratory was created to carry on activities of ordnance design and delivery of atomic bombs. Jerrold Zacharias, who had been active in the radar group of the Massachusetts Institute of Technology Radiation Laboratory, was selected to head this new organization, the Z nomenclature stemming from the first letter of his last name.

The broad area of responsibility of the new Division was indicated in a memorandum dated August 6, 1945, from Dr. Zacharias to J. Robert Oppenheimer, Director of the Los Alamos Laboratory. In part, the memorandum read:

> "With the organization of Z Division in such a fluid state, it is tempting to put nothing on paper. The Division is likely to become larger and to take on so many duties of so many different divisions that a more vertical organization than is usual in Project Y [Los Alamos] will have to be sought."

Dr. Zacharias then proposed an organizational breakdown of the Division, with work assignments as follows:

Z-1, Experimental Systems Engineering, to perform airborne testing, ballistics, aerodynamics, radar, and informer or telemetering work.

Z-2, Assembly Factory and Procurement, to procure, assemble, and ship weapons.

Z-3, Electrical Engineering, to design firing circuits and detonators.

Z-4, Mechanical Engineering for Production, to be concerned with general engineering changes, and--most pertinent to this history--the "coordination of development of streamlined gadget" (i.e., the Mk 4).

Z-5, Electronic Engineering, to handle fuze development.

Dr. Zacharias predicted that some of these groups would move to Sandia, but that the engineering people would probably remain at Los Alamos.[2]

On August 8, 1945, the day before the first--and also last--Fat Man weapon ever to be used in combat was detonated over the Japanese city of Nagasaki, a memorandum was released which outlined the Fat Man design problems in considerable detail, pointing out that it was necessary "to simplify and render more reproducible assembly of FM, to improve ballistics of FM, to incorporate simplification and developments of the individual components." Mandatory requirements were to maintain the ability to monitor the weapon battery and electrical system while the weapon was being carried to the target and to keep the weapon small enough to fit into the B-29 bomb bay. Desirable objectives were to provide rapid bomb assembly, permit testing and inspection without disturbing component parts, allow shipment of a practically complete weapon (less detonators and nuclear material), provide armor to protect the bomb against shrapnel, and maintain dry air within the weapon.[3] Thus, the design task was defined and the stage set for development work.

Chapter II - Early Development

It now became necessary to provide adequate space and facilities for the work of the Z Division. The first step in this direction was taken in the fall of 1945, when the Engineering Division of Los Alamos was requested to design a testing laboratory. This laboratory would simulate on the ground the conditions which bombs and components experienced in flight. This testing laboratory was subsequently built and proved of material assistance in the development of the new weapon.

Meanwhile, a proper work location for the assembly group, Z-2, was being discussed. This organization, which was largely staffed with military and Civil Service personnel, could be administratively separated from the rest of the Division, and required an area convenient to air and rail transportation. A logical spot was the former Oxnard Field, the original Albuquerque Airport (now called Sandia Base), which already was the property of the Manhattan Engineer District, having been obtained in July 1945 for the never-consummated objective of providing space for temporary storage of atomic-bomb materiel during World War II. A meeting was held at Sandia August 29, 1945, at which time it was decided to transfer Z-2 to Sandia Base. It was also decided to remove the W-47 Flight Test Group from Wendover Field, Utah, and bring some of these personnel to Sandia Base.[4] After further discussion, it was decided that weapons production and test activities would be concentrated at Sandia and design work at Los Alamos.[5]

The first Z-Division representatives moved from Los Alamos to Sandia Base September 27, 1945, and on the following day Dr. Zacharias inaugurated the practice of issuing monthly progress reports.[6] The initial report of the Mechanical Engineering Group, Z-4, noted that work on the Fat Man was directed toward making this bomb a more reliable and serviceable weapon--more of a re-engineering task than a radical redesign of the entire gadget.

("Gadget" was a common term in those days for an atomic device.) The report pointed out that the Mk III had to be assembled component by component, while it was hoped that the new bomb could be put together in fairly large subassemblies. In line with this objective, a start had been made in consolidating some of the electrical items into a "cartridge" that could be inserted into the weapon as a unit (in the same manner that a cartridge was inserted in the chamber of a rifle).

A conference between military and Z-Division personnel had meanwhile been held at Wright Field, Ohio, September 21, 1945, to review aircraft capable of carrying the proposed bomb. The B-36 long-range bomber was in the last phases of design and was nearing the flight-test stage, and several jet-propelled medium bombers were being developed. However, the B-36 had a relatively low top speed, and the jet bombers (at that time) were restricted in range, so it was concluded that any immediate redesign of the Fat Man must, of necessity, keep the B-29 in mind as the delivery vehicle.[7]

A Mk 4 planning meeting was held October 4, 1945, at which an optimistic schedule was laid out. The coefficient of expansion of the high-explosive sphere was to be determined by November 1, 1945. The external shape of the bomb and the elements of the firing circuitry were to be settled by December 1, and the sphere assembly and mounting were to be designed by December 15. Drawings of the tail, the cartridge, and the electrical equipment were to be prepared by January 1, 1946. Handling equipment was to be available by February 1; full-scale drops were to be started March 15; a pit and sphere assembly was to be completed by May 15; and the entire bomb was to be ready for stockpile production, with all problems solved, by July 1, 1946. (b)(3)

It is obvious ... that the

estimated date of July 1 for the completed bomb is contingent on the progress made with the pit."[6] However, it was understood that, should the nuclear design be produced, the weapons hardware group was to be ready with the rest of the bomb, and the Z Division swung into high gear.

During design of the wartime Fat Man, there had not been enough time to make a thorough analysis of component functions and their relationships to the overall weapon system. A study was thus started, covering the circuit elements of the bomb and the part played by such factors as simultaneity of switch operation in overall efficiency. Ballistic problems, further described in Chapter III, also were examined. To meet this need, a field-test range was secured, arrangements made for wind-tunnel work, and special telemetry apparatus started into design.

Improvements were made to various elements of the firing system, notably the X-unit, which created the high-voltage surge of current that fired the weapon detonators. The wartime implosion bomb had been equipped with an X-unit whose capacitors were charged to approximately 5600 volts before the bomb was released from the carrying airplane. This not only created a hazard to the bomber crew, but made it necessary to pressurize the X-unit to prevent internal arcing at bomb release altitudes. A safer and simpler X-unit was designed, which was charged after the bomb had fallen to its fuzing altitude, a safe distance from the strike aircraft.

Detonators were modified for easier installation, and much attention was paid to the design of segment molds and the lenses for most efficient implosion of the high-explosive sphere. Extensive tests were made of face pressures between high-explosive segments, and studies were conducted of improved systems of detonator cabling. The protruding Mk III (Yagi) antennas were redesigned to be recessed into the flattened nose of the

The above effort was compounded by the necessity to provide parallel designs for mockup or dummy units. Detonators, for example, were built with inert charges so that they could safely be used in trial sphere assemblies using, of course, dummy high-explosive segments. Various operational units had to be simulated by dummy weights so that these could be attached to assemblies being given shake-table tests.

The Mk 4 work was later delayed by another full-scale test, Operation Sandstone, which was held at Eniwetok in mid-1948. Mr. Henderson headed up the engineering phase of the operation, and Z-Division personnel were assigned to various Sandstone functions. However, as the year 1947 drew to a close, the following accomplishments related to the Mk 4 weapon could be reported to Congress in reply to a request for the status of nuclear ordnance:

1. Selection of an outer case with improved ballistics;
2. Progress on a new fin design;
3. Development of a new antenna system;
4. Development of a cartridge-type assembly to contain bomb fuzing components;
5. Development of new handling equipment;
6. Preliminary studies of a new radar and electromechanical fuze;
7. Establishment of a mechanical test laboratory; and
8. Extensive work in the field of telemetry.[11]

For some time there had been proposals to separate the Z Division from the rest of the Los Alamos Scientific Laboratory. Los Alamos interests were basically that of an experimental nuclear and scientific laboratory, while the Z-Division work was rapidly assuming the aspects of ordnance design and production. This trend brought about the appointment on

In the meantime, at Kirtland Field, members of the Tactical and Technical Liaison Committee, established by the Air Force in connection with the atomic bomb, were also studying this subject. On March 26, 1948, the Committee recommended to Air Force Headquarters that both insertion and extraction of nuclear components be provided, pointing out that such design would increase both aircraft and airport safety. The practicality of this insertion and extraction operation had meanwhile been demonstrated by members of the Z Division working inside a parked B-29 at Kirtland Field.[14] This subject was further discussed in the Sandia Research and Development Board meeting of July 20, 1948, in which it was noted that the problem of extraction was of concern, but that it was necessary to freeze the design to permit production to proceed. Accordingly, action on the problem was temporarily deferred.[15]

Meanwhile, international tensions were increasing. The Communists had seized Czechoslovakia and were being belligerent in Berlin, where the Western powers occupied part of the city as an island in the midst of Soviet-held territory. As a result, the Military Liaison Committee urged that production and stockpiling of the Mk 4 be expedited.[16] The Sandia Research and Development Board discussed assignment of priorities for various atomic programs and, in a meeting May 6, 1948, urged the acceleration of the Mk 4 by every means possible.[17] Working at high speed and under overtime schedules, Sandia released portions of the Mk 4 design as they were completed, and by mid-November 1948 the entire weapon was in production.[18]

It was felt that the Mk 4 could be stockpiled by April 1, 1949.[19] The Preliminary Evaluation Report for the weapon, which provided an engineering examination of the bomb and gaged its success in meeting

specifications, was issued January 15, 1949. A crash program produced test and handling equipment for military training and for possible emergency use.[20] As a result of this intensive effort, the first Mk 4 Bomb entered stockpile March 19, 1949.[21]

Chapter III - The Ballistics Problem

The problem of Mk 4 ballistics received early attention. The Mk III weapon had a diameter of 5 feet to accommodate its large explosive sphere, and a proportionally short length (~~11 feet~~ 10 feet 7 inches) to enable the weapon to fit into the B-29 bomb bay. A 5-foot-square box tail was initially used, and this design was only marginally aerodynamically stable after the tail structure had been internally stiffened and braced. The ballistics group at Los Alamos suggested that the center of gravity be moved as far forward as possible and that the body and tail be streamlined to the utmost. A tail design to provide lift rather than drag as a stabilizing force was advocated, as well as a structural design to minimize vibration and flutter, the location of internal components for best static and dynamic balance, and the elimination of external projections that might cause turbulence or parasitic drag. The report noted that the Mk III had a low ballistic coefficient, that this figure should be increased to improve stability, but that the stubby shape of the bomb would militate against any large increase.

A meeting of Los Alamos and W-47 representatives was held August 25, 1945, to provide an answer to the ballistics problem. Some attendees felt that if the bomb could be lengthened, a relatively high ballistic coefficient might be attained. (b)(1), (b)(3)

This was found to be impractical, due to the large diameter of the Mk 4 and the lack of sufficient clearance under the fuselage of the B-29. As one result of the meeting, it was decided to seek external ballistics advice.[22]

Two days later, Z-Division representatives left for the East Coast to visit the Bureau of Standards, the Aberdeen Ballistics Laboratory, and Langley

Field; and to confer with aerodynamicists and ballistics experts. They were informed that the best tail was a design using four equally spaced airfoils, and that these airfoils had to extend some distance out from the body of the bomb since, at high velocities, the air flow broke away from the bomb contour at approximately the maximum diameter of the bomb. It was felt unwise to permit the velocity of the bomb to exceed Mach 1 (the speed of sound), due to buildup of vibration, and it was suggested that a tail shroud be used to retard the rate of fall of the bomb if this velocity was approached in full-scale drops. The use of a blunt rather than a round nose was recommended in an effort to further retard the rate of fall.

A wind-tunnel test program was outlined, to be conducted at Aberdeen. Body shapes without tails would be initially investigated, and the best shapes fitted with simple fins and tested further. If these designs were not completely stable, a circular tail shroud would be added. These wind-tunnel tests would be made at speeds expected to be encountered in actual drops, and stability of the bomb shapes at higher or supersonic speeds would be checked by firing 20-millimeter-diameter models from a gun. It was felt that little could be done to improve the body of the bomb, due to the dimensional limitations imposed by high-explosive sphere and bomb bay, and that efforts should be concentrated on tail modifications.[22]

It had been decided to start full-scale test drops as soon as possible, and an aerial survey of World War II practice ranges in the vicinity of Albuquerque was made September 19, 1945, by members of Z-1. As a result, Range S-1 (which was renamed the Los Lunas Range) was selected for use. This range was located west of the town of Los Lunas and approximately 25 miles southwest of Albuquerque.[23]

In preparation for the work at Los Lunas, recording and communications gear was installed in trailers which could be based at Albuquerque and

trajectory (and thus a high bomb velocity), and to test bomb operation in a denser atmosphere. The range had been obtained for the Z Division in March 1946, and initially used for Mk III tests. Subsequently, much preparatory work was done at Salton Sea, with Askania stations being established, targets prepared, field communication wire strung along the ground, and radio transmitting and receiving equipment installed.[9]

A half-scale Mk 4 shape was dropped at Salton Sea April 4, 1947. The test demonstrated that the approaching B-29 bombers were hard to see, and this fact, coupled with inaccurate bombing, complicated tracking and camera work. The B-29's developed mechanical trouble as the high-altitude work continued, and electrical problems were created as the wild life around Salton Sea acquired a taste for the insulation of the ground-laid wires. Test operations were temporarily halted while new B-29's were secured, wiring strung on poles, and a new target array installed.[25]

By the fall of 1947, it was felt that if the roll of the bomb in flight could be controlled, many erratic ballistic actions could be eliminated. One way of controlling roll was to provide a tail that would spin freely, and this was tried. It involved difficult manufacturing problems and was therefore not thoroughly pursued. Another proposal was to use the shroud that had been initially proposed as a means of providing drag. This shroud would add considerable weight to the tail, thus adversely shifting the center of gravity aft, and designs were tested for a lightweight tail cone to counter this added weight.[26]

By early March 1948, drop tests were indicating improved ballistic characteristics. Releases to supply performance data on fin shape indicated that a large-plan fin (with an area increased approximately 25 percent above the plan area of the standard fin) would produce

less yaw in flight than the standard fin. Fairly consistent performance was also obtained using a thin fin (with a plan area decreased approximately 25 percent) and a circular shroud. Neither of these two types, however, gave completely satisfactory ballistic performance.[27]

Members of the Armed Forces Special Weapons Project suggested that a group of aerodynamicists might be able to suggest improvements in ballistic characteristics, inasmuch as a great deal had recently been learned concerning actions of bodies passing through the transonic region, which had been pierced by manned aircraft only a few months previously. Consequently, representatives of Northrop, Rand, Douglas, North American, Boeing, Wright-Patterson Air Force Base, Inyokern, and Aberdeen formed an advisory panel which initially met May 26 and 27, 1948. The panel suggested that thin fins with flat sides and wedge cross sections would perform better than fins with curved sides and airfoil cross sections. It was also proposed that the planform of the fin be enlarged and drag introduced by the use of plates or spoilers to hold the velocity of the bomb below the transonic range. Arrangements were made to use the Cooperative Wind Tunnel at the California Institute of Technology, which had a greater velocity range than the Aberdeen tunnel.[28]

The flat-sided wedge fins were subsequently tested at the Cooperative Wind Tunnel and exhibited good stability.[22] Consistently good results were obtained from drop tests and, in mid-September 1948, the large-plan wedge fin was tentatively selected for use.[29,30] Detailed results of tests at the Cooperative Wind Tunnel became available October 1, 1948, and confirmed the results noted above. Perforated tail plates were tested on two bombs; one with a square plate and the other circular. The first gave improved control over pitch and yaw, while the second resulted in decreased control--hardly a conclusive test.

Since there was now a limited amount of time and drop tests that could be made, it was decided to concentrate on trials of a large-plan wedge, a thin-fin shroud wedge, a dorsal wedge, and a large plan with a sloping leading edge. All these, it was felt, would have about the same ballistic characteristics. A closer examination of wind-tunnel data subsequently narrowed the choice to a large-plan wedge or a thin-fin shroud wedge. It was then found that the reliability of the thin-fin shroud declined in high-speed, high-altitude drops, whereas the large-plan wedge did not, and the latter design became the obvious choice.

Aberdeen wartime experience with certain experimental bombs had indicated that a "flap" placed at the rear of a bomb shroud (which presented a greater angle of attack to the approaching air than the fin) would help to stabilize bomb flight, and large-plan wedge and thin-fin shroud tails were prepared with this modification. The first to be dropped was the large-plan wedge. One drop showed such excellent flight characteristics--with pitch and yaw of only about 2-1/2 degrees and a ballistic velocity coefficient only slightly lower than that of the thin-fin shroud--that it was deemed advisable to concentrate on further drops of this type, rather than expending time and energy on the thin-fin shroud, which was difficult to fabricate.[22] Accordingly, the large-plan wedge design was frozen for Road production in December 1948.

(b)(1), (b)(3)

Chapter IV - Mk 4 Bomb Description

Since the Mk III Bomb was the immediate predecessor of the Mk 4, a brief review of its major design features is of interest. (b)(3)

The Mod 1 retained the Type A pit, but incorporated an improved fuzing and firing system including the Mk III Mod 2 X-unit (an inductance type), ER-12-10 batteries, and 1E20 detonators. (b)(3)

The original Mk 4 Mod 0 Bomb was similar in many respects to the Mk III Mod 2 (see Figure 2). (b)(3)

The Mk 4 was a free-fall, air-burst, implosion-type bomb 60 inches in diameter and 128 inches long, and weighing 10,900 pounds.[37] (b)(1), (b)(3)

These yields compared to the wartime "Little Boy" and "Fat Man" bombs of 18 and 23 kilotons, respectively.[40] (b)(3)

The external ballistic case was made of mild steel, 3/8 inch thick, and was built in three sections for ease of assembly.[37] The front and rear sections bolted directly onto the fore and aft flanges of the sphere

case. The center "belly band" section was split at the top so that it could be spread apart with assembly tools and slipped over the sphere flanges for positioning over the center section of the sphere. Tension bolts pulled the split-band together at the top. A large rubber gasket sealed the surfaces where the steel case met the aluminum sphere case. The forward case supported the antenna nose plate, which could be removed for access to the sphere. The inflight insertion gear was supported by the forward case. The four fins, which were of aluminum sheet-metal construction, were bolted to the rear case.

(b)(3)

The cartridge structure supported the fuzing components, was cylindrical in shape, and used riveted aluminum sheet-metal construction. The X-unit was bolted to the forward end of this assembly, and the entire unit was

(b)(1), (b)(3)

The following aircraft were equipped to deliver the Mk 4. For the Air Force; B-29, B-36D, B-36F, B-47B, B-50A, and B-50D. For the Navy; AJ1 and AJ2. Since the Mk 4 was originally designed for carriage by B-29 and similar land-based aircraft, no provision had been made for resisting catapult loads. With the development of Navy aircraft capable of taking off with the bomb from the deck of an aircraft carrier, some difficulty at the sway-brace locations was encountered. This was overcome by redesigning the sway braces in the aircraft bomb bay so as to distribute the load over a sufficient area to prevent damage to the outer case of the Mk 4.

The Mk 4 Mod 0 Bomb entered stockpile March 1949. It was not equipped for inflight nuclear insertion. It included the Type C pit and had an inflatable rubber gasket to seal the ballistic case. Baro ports were located at the nose of the bomb, and the entire interior of the bomb case was used as a "plenum chamber" to provide static pressure to the baroswitches.

The "Mod-Alt" change system was not in use at this time, and major changes were processed under a "block" change system. All weapons in a given "block" of units incorporated the same changes. In May 1950 the Mk-Mod-Alt weapon designation system was instituted, and the weapon was divided into three major assemblies, bomb, fuze, and capsule.[42] The bomb capable of inflight nuclear insertion became the Mk 4 Mod 1

(previously identified as the Block 7 weapon). It also included a solid rubber gasket for sealing the ballistic case. Since it had a Type C pit, the complete bomb nomenclature was Mk 4 Mod 1-C.

The Mk 4 Mod 2-C Bomb incorporated a baro manifold, which was a circular copper tubing assembly installed in the rear ballistic case.[43] Static pressure was provided from intake ports in the rear cover plate through flexible hose leading to the manifold and additional flexible hose connected the manifold to the baroswitches. The accuracy of the baro system was improved by this change, since it no longer depended on a sealed ballistic case for a static pressure source.

The Mk 4 Mod 2-D Bomb incorporated a Type D pit with a higher yield.[44] Special handling equipment was required for insertion of this capsule into the pit, and included a loading tool and a capsule alignment tool or loading trough. By the end of 1951, all Mk 4's had been retrofitted to the Type D pit.[45]

The Mk 4 Mod 3 Bomb incorporated a lightweight magnesium antenna nose plate for easy manual handling. This permitted simplification of the inflight nuclear insertion gear and speeded the operation. Since this change was incorporated on bombs having either the Type C or D pit, it was identified as the Mod 3-C or Mod 3-D.

The "cartridge" became, under the new system, the Mk 4 Mod 1 Fuze. This included the AR-10A "Archie" radars (four required), BS-4 or BS-5 Baroswitches (six required), M-127 "clock" timers (eight required), Mk 4 X-unit, and lead-acid ER-12-10 batteries. The components were mounted on an aluminum structure for convenient installation (b)(3)

interval before supplying power to the firing set. This time interval allowed the airplane to get beyond radar fuzing range, preventing premature detonation by radars ranging off the aircraft. Closing of the arming switches by the clocks allowed current from the 30-volt battery packs to flow through the X-unit choke and the closed firing switch. This current flow caused a magnetic field to be built up in the choke.

At a predetermined altitude, well above the desired burst height, baroswitches closed, allowing the radars to start transmitting and receiving. At the preset burst height, the ranging of any two of the four radars off the target operated a relay network which opened the firing switch in the X-unit. The rapid opening of this firing switch caused a collapse of the magnetic field in the choke, transferring electrical energy to a condenser. When the voltage in the condenser built up to approximately 4000 volts, the spark-gap switch spontaneously broke down, allowing current to flow through the gap and the detonator circuits.

Bridge wires in the detonators were vaporized by the high-voltage pulse. This detonated the explosive material in the detonators, which in turn ignited the high-explosive charges of the sphere, creating a spherically convergent detonation wave which compressed the nuclear components to supercriticality.

(b)(1), (b)(3)

Chapter V - Mk 4 Improvement

After the Mk 4 entered stockpile, design improvements continued despite the fact that much of the engineering staff was transferred to work on other weapons. A list of desirable modifications was compiled, based on a joint military-Sandia survey, and, after thorough review, was formally issued May 18, 1949, under the title "Desired Military and Technical Characteristics of FM Type Atomic Weapons."[48]

Five areas were listed, including weapon battery, ballistics, inflight nuclear insertion and extraction, lightweight case, and improved fuzing system. Battery improvement, due to the state of the art, was deferred for later consideration; the ballistics story has been developed in Chapter III.

The inflight nuclear insertion and extraction project was already well under way, as studies had started in early 1948, (b)(3)

Facilities for supporting the antenna nose plate and sphere access door while the nuclear capsule was being guided into position were also provided. This support device was temporarily bolted to the nose of the bomb while it was in the bomb bay of the aircraft proceeding to target, and was manually operated.[18] A later production version eliminated the support arms for the nose plate and access door, which by that time had been much reduced in weight.

(b)(3)

It was originally felt that the Mk 4 should be protected against flak by an outer case of 1/4-inch-thick armor plate. Those attending the August 25, 1945, meeting that discussed general bomb features had felt that this protection was unnecessary,[22] and as a result the weapon was constructed with a case of 3/8 inch-thick mild steel. The Bureau of Ordnance later noted that aluminum offered somewhat better protection than steel, when equal weights of materials were used, and as a result some reduced-scale aluminum cases of 3/4-inch thickness were designed, built, and drop tested in 1947. However, the fact that strong steel cases were normally used in bomb construction led the Mk 4 designers back to this material.

The Air Force was of course vitally interested in anything that would reduce the weight of the bombs they carried, in order to increase the range and altitude of the carrying aircraft, and this subject was discussed in various meetings at Kirtland Field and the Los Alamos Scientific Laboratory during the fall of 1948.[51] Sandia Laboratory forwarded a memorandum to the Division of Military Application on September 29, 1948, stating that it should be possible to reduce the weight of the Mk 4 by using aircraft-type design in the front and rear case sections, but that this work would delay the Mk 4 stockpile delivery date.[52] It was suggested that some preliminary design be undertaken by aircraft engineers cleared as members of the aerodynamics panel.

This topic was mentioned in the September 30, 1948, meeting of the Sandia Research and Development Board, with Sandia pointing out that the change would necessitate a major change in material sources, tooling, and bomb handling equipment, and that a thorough stress analysis would be required.

Subsequently, considerable correspondence on the subject developed between the Division of Military Application, Military Liaison Committee, AEC, and Sandia, with efforts being made to determine whether or not there was a real need for the heavy case for either flak protection or storage.[53,54,55,56] On December 24, 1948, Sandia informed AEC that a development program for reduction of Mk 4 Bomb weight had been established at Project Roger (the Army's Rock Island Arsenal, which was handling certain weapons production work) and its subcontractor, the American Car and Foundry Company. The purpose of this program was to evaluate and recommend weight reductions based on an aluminum outer case produced by the same tools used for forming the steel casing.[57]

Meanwhile, various pressures were exerted both for and against the design of a lightweight case,[58,59,60] with the matter being decided February 17, 1949, when the Division of Military Application directed Sandia to subcontract the design of an aluminum case.[61] On March 16, Northrop Aircraft, Inc., was invited to design a riveted case,[62] and in May the American Car and Foundry Company was asked to design a welded case.

Ballistic testing of both the riveted and welded cases was conducted in December 1949, and static and dynamic tests were run at Wright Field.[63] These proved that both cases were satisfactory, and, inasmuch as cost and weight comparisons were roughly equivalent, it was decided to procure both types.[64,65,66,67] Production of the riveted design was turned over to Project Royal (the AEC manufacturing facility at Kansas City), and the

UNCLASSIFIED

American Car and Foundry Company started to fabricate the welded case. A memorandum from Sandia to the AEC April 5, 1950, noted the desirability of minimum weights for all bomb components, and stated that Sandia was investigating the possibility of also reducing the weight of the inner sphere case.[68] However, about this time, the entire weight-reduction program was transferred from the Mk 4 to the Mk 6 design.

(b)(1), (b)(3)

Design and production problems were encountered with the Abee and, for a time in late 1949 and early 1950, consideration was given to a simple barometric fuze. However, the Los Alamos requirement that the bomb detonate at a relatively precise distance above the target inevitably brought the designers back to consideration of a radar fuze.

Meanwhile, some short-range improvements were made to the Archie.[69] Various range (height of burst) modifications had been provided by the use of separate delay lines that were soldered into the instrument for each range. This made it difficult to alter the height of burst rapidly when targets were changed,[70] and in the fall of 1949, a modified Archie (AR-10A) with plug-in delay lines was introduced, eliminating the soldering task. A still more powerful radar (to be called Albert) was proposed, and work proceeded intermittently on this design.

At a meeting of the Sandia Research and Development Board, on September 19, 1949, an addition of a "Black Box" to the radar system was considered.

UNCLASSIFIED

(D). Comparative Description of Bombs

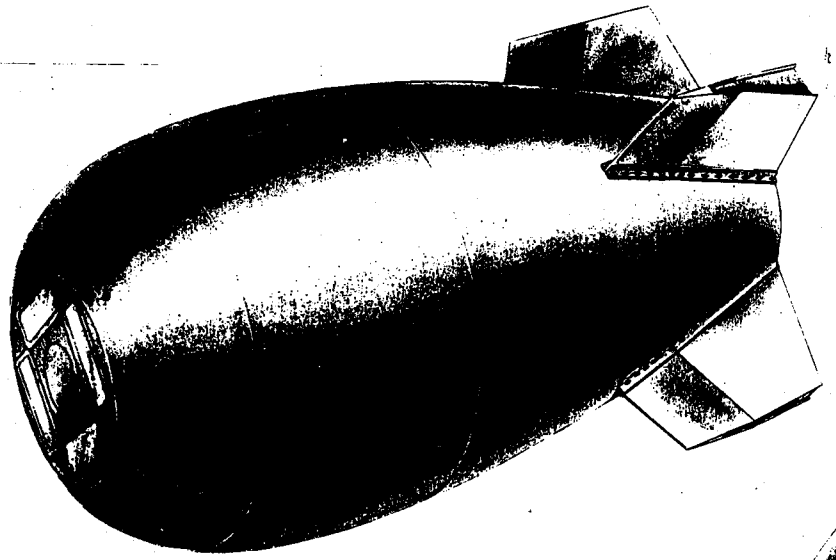

Figure 1 shows the Mk IV and Mk III FM bombs assembled. It will be noted that in external appearance the Mk IV is much cleaner in design. The ellipsoid and tail fittings, the antennas, and the bomb lug have been eliminated as protuberances. The lug is recessed, and the antennas are flush-mounted in the noseplate. The complex box tail of the Mk III has been replaced by four airfoil-type fins.

Figures 2 through 6 illustrate the weapons and their components, and Figure 7 compares the breakdown of major components of the two weapons. The difference that is most readily apparent is the placement and mounting of the electronic fuzing and firing equipment into one easily removable cartridge rather than on cones placed on opposite sides of the sphere. A study of these pictures will identify the corresponding components of the two weapons.

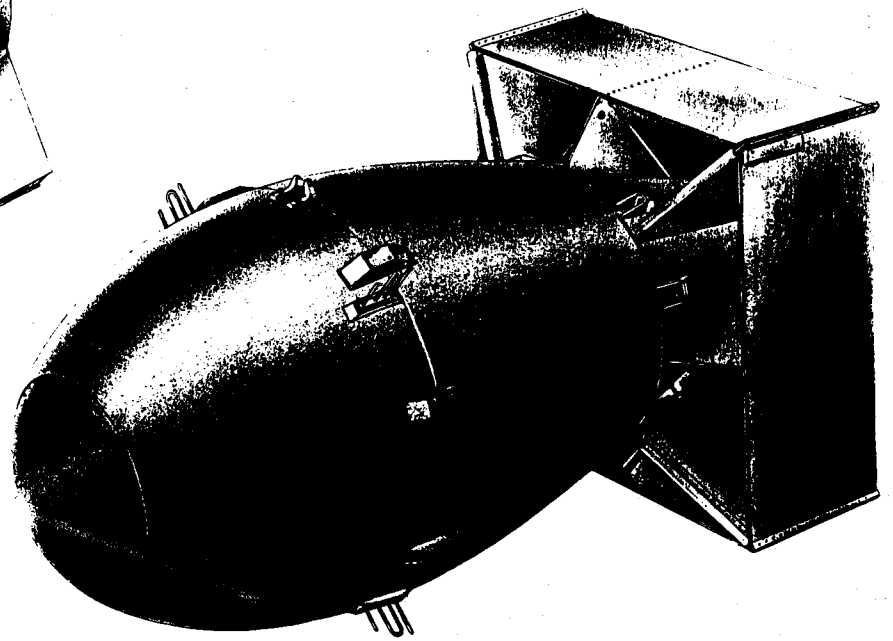

Figure 8 illustrates and compares the field assembly breakdown of the weapons. In this figure the split-band is removed from the Mk IV for installation of the detonators. The comparison clearly illustrates the greater simplicity in field assembly of the Mk IV.

Figure 9 illustrates and compares the field assembly breakdown of the weapons when the detonators are installed in the Mk IV at the rear base. It can be seen that further simplification is achieved if the detonators are installed before the bomb goes forward.

(J). Nuclear Components

(II). MK IV MOD 0 FM BOMB

(A). OVER-ALL DESIGN OF BOMB

(1). Functional Use and Design Requirements

The Mk IV Mod 0 FM is an implosion-type atomic bomb based upon the same fundamental principles of nuclear fission as those of the Mk III FM. It incorporates an improved fuzing and firing circuitry over that in the Mk III Mod 0 weapon and the same basic circuitry as that in the Mk III Mod I weapon. The bomb was re-engineered to provide for greater ruggedness, greater dependability, easier field techniques, and better ballistic performance than either of the Mk III versions.

In addition to the detailed discussion of these various factors presented in later sections of this chapter, the following general requirements, which apply to the entire bomb, are discussed in this section.

(a). The bomb must withstand expected flight and handling loads.

(b). The bomb must withstand atmospheric conditions as required for storage and operation.

(c). The external dimensions of the bomb must be kept within the box dimensions of the Mk III FM and must be such that the bomb will fit into a B-29 bomb bay.

(2). Discussion, Tests, and Calculations

(a). Flight Handling Loads. -- Calculations and tests indicate that the bomb will withstand the following load factors shown in the memorandum "Minutes of Meeting to Establish Load Factors for '41'," (Ref SLE-3-1477): 1,2

Airplane Flight Loads (S.F. = 1.5)

	Limit	Ultimate
Vertical	4.67 down	7.0 down
	2.0 up	3.0 up
Longitudinal	4.0 aft	6.0 aft
	5.33 fwd	8.0 fwd
Lateral	2.0	3.0

Free Flight Loads

A resultant static fin load equal to the weight of the bomb and located 1/3 of the fin height from the base of the fin.

Ground Handling

	Limit	Ultimate
Vertical	+4	+6
	-2	-3 (based on trailer weight)
Longitudinal	6	9
Lateral	2	3

The bomb is designed to withstand normal handling load factors while being assembled or while being transported by any practicable surface or air means. An empirical standard of vibration testing of 10 to 55 cps constant amplitude at 10 g maximum acceleration for 45 minutes in each of three

mutually perpendicular planes has been adopted for certain components. Although complete knowledge of transport vibration is not available at this time, some data have been received.

Additional information is being obtained and a study is in progress to determine the application of this information to design.[3,4] Present calculations and experience show that the bomb has adequate factors of safety to withstand all but the most exceptional transport loads. Vibrations recorded during drop tests indicate that all components have adequate factors of safety for free flight conditions.[5] Actual drop tests with HE have not been made.

There has been considerable experience in the use of assembled test bombs without any failures caused by normal handling.

A Mk IV Mod 0 FM unit loaded with dummy charges and electrically functional was subjected to abnormal handling when the trailer on which the unit was being towed broke down. An electrical check and inspection of the unit was made after the accident. Aside from fin damage and minor scratches on the outside of the case, no failures were found.[6]

(b). Environmental Limitations. -- The original engineering concepts of atomic bombs required that each unit be handled under specific, carefully controlled conditions in both storage and use. The growth of storage and tactical philosophies has created the desire to provide for the storage and use of atomic weapons under highly adverse atmospheric conditions. The Mk IV FM partly fulfills this long-range development ideal. A chart showing the recommended limiting environment for components is shown on pages 27-29.

(1). Long-Term Storage (Nonoperational). -- It is estimated that the components of the unit in long-term dead storage can withstand temperatures ranging from -40°F to 149°F with the exception of the HE assembly (long-term high temperature of 95°F to 100°F maximum, and slow rate of temperature change). For long-term storage most of the components should not be exposed to relative humidities greater than 40 per cent; all components are therefore packaged to provide protection against moisture. All components except the nuclear material, batteries, detonators, and

cartridge are stored in the bomb case. The assembled bomb case, which is stored in a crate, breathes through one desiccator port. A desiccant is placed inside the case for protection against moisture. All other components are packaged under Method II A (dry-air technique). By this method the item is packaged in a moisture-proof barrier along with a sufficient amount of desiccant.

(2). Exposure During Assembly. -- The relative humidity in the assembly area should not be greater than 50 per cent at 80°F.

(3). Exposure of Completely Assembled Bomb. -- It is estimated that the assembled bomb can be exposed to temperatures as low as -40°F for at least as long as the life of the desiccators (approximately two weeks) provided the battery temperature is increased to above 0°F before use. It is also estimated that the bomb, less its nuclear components, can be exposed to 120°F for two weeks. With nuclear components, the bomb can be exposed to temperatures up to 120°F for three days and up to 105°F for two weeks.

Leakage tests indicate that the outer case sealing will protect the assembled bomb from exposure to relative humidities up to 100 per cent for moderately long periods providing the desiccators are replaced when necessary (every two weeks).

(4). Operational - General. -- Drop tests of the Mk IV Mod 0 FM as well as laboratory component tests have indicated that the bomb will operate satisfactorily at temperatures ranging from -40°F (with heaters functioning in the clock bank and battery box) to 120°F, at pressures ranging from atmospheric to 7 psi, and at relative humidities of 80 to 90 per cent.

The temperatures of the internal components at detonation is not definitely known; it is expected, however, because of the short time of fall, that the temperatures will be very close to those at the time of release. Tests indicate that the temperature inside the bomb bay with a Mk III Mod 0 bomb in it will stabilize at about 25°F to 28°F above free air temperature (Ref SMD-575, Preliminary Investigation of B-29 Bomb Bay Temperatures). Tests on a Mk III Mod 0 bomb indicate that it takes at least four hours for the temperature of the internal components to reach -40°F when the temperature of the air to which the bomb is exposed is rapidly changed from 70°F to -65°F (Ref SMD-435, Low Temperature Tests of a Nagasaki-type Bomb). These tests also indicate that it takes at least eight hours for the temperatures of the internal components to change from 70°F to -65°F when the air temperature is -65°F. On the basis of the results of these tests, it is believed that the temperature of internal components will not be below -40°F when free air temperature at altitude is -65°F or above.

(c). Dimensional Limitations. -- The over-all dimensions on the bomb were limited to the box dimensions (60 x 60 x 128 inches) of the Mk III FM, and were to be such that the bomb would fit in a B-29 bomb bay. Tolerances on drawings allow the external diameter of the bomb to exceed 60 inches by 0.16 inch. The bomb fits into the bomb bays of the B-29, B-50, AJ-1, and B-36 airplanes. The distances between the fin guide rails in the B-29 bomb bay dictated, for clearance purposes, a 59-inch box dimension for the fins.

The total weight of the bomb is 10,900 ±240 pounds, and the cg is 43-7/16 ± 1/4 inches from the nose; the transverse moment of inertia is approximately 9,400,000 in.^{2} lbs and the polar moment of inertia is approximately 4,400,00 in.^{2} lbs. Component weights of one unit are tabulated on page 30.

(d). Other Limitations. -- The unit, less its nuclear material, after being tested and assembled, can be dispersed for a period of two weeks without rechecking. Two weeks is the estimated life of the desiccators. The batteries will maintain proper charge for a period of three weeks.

There are four airplanes which can accommodate the bomb at present, the B-29, B-50, AJ-1, and B-36. Satisfactory ballistic drop-tests have also been made from the B-47, but as yet it is not wired for making the electrical checks required in flight.

The best predictable results can be obtained in all drops that are made from an altitude of 32,000 feet at normal B-29 release velocity (310 mph true air speed). However, satisfactory drops can be made at altitudes up to at least 40,000 feet and at release velocities up to 0.8 Mach number.

Drop data indicate a trend in the increase of baro-switch pressure of approximately 440 feet altitude per 100-mph true air speed increase in release velocity. For normal B-29 drops this effect is so small as to make it impracticable to correct the baro-switch setting. However, if release velocities vary over a wide range, corrections should be made.

No definite effect of variation in release altitude from 32,000 to 40,000 feet has been noted from tests conducted to date. There is an indication that lower release altitudes may cause baro switches to close at higher than normal altitudes. Insufficient data exist at this time to establish definitely the effect of variation in release altitudes upon baro-switch closure. Baro-switch closure can, however, be most closely predicated at drops from 32,000 feet. Consideration should therefore be given to making drops at or near this altitude whenever radar jamming is expected.

Weather limitations during drops are not accurately known; however, it might be expected that all-weather use of this weapon can be made only at the possible expense of performance.

Atmospheric turbulence, with rare exceptions, will affect the ballistic accuracy of the bomb by only 100 to 200 feet. If unpredicted ballistic winds, such as might be encountered in a cumulus cloud, reach 100 mph or more, the impact point may vary as much as 1000 feet.

Present indications are that a fairly large reduction in blast efficiency may result from detonation in rain or fog. The probability of the Archies' ranging on clouds is very low.

The effects of icing during a drop are not definitely known. The ballistic performance, antenna operation, and baro-switch operation may be affected to a certain degree by accretion of ice upon the unit. However, on the basis of existing limited knowledge, it is believed that the probability of detrimental effect of icing is low unless severe icing conditions are encountered.

(e). Dependence upon Personnel Performance. -- The simplicity of the design of the Mk IV Mod 0 FM and the reduction of necessary assembling and testing in the field greatly lessen the probability of human error; therefore the quality of personnel in the field need not be as good as that required for the Mk III without sacrificing reliability. However, because of the importance of proper functioning of this weapon, all operations should be performed by thoroughly trained personnel.

Component Weight Breakdown of Mk IV Mod 0 FM

Item	Weight (lbs)
Completely Assembled Unit	10,866

(B). OUTER CASE

(1). Functional Use and Design Requirements

The outer case of the bomb serves to provide

(a). An adequate structural member on which the tail fins and antennas can be mounted;

(b). A housing for protecting the internal components against damage from handling, weather, and low-velocity fragment damage; and

(c). A suitable ballistic contour.

In addition to performing those functions, the case has the following design requirements to meet:

(a). Accessibility must be provided to the detonators on the sphere with a minimum of disassembly in the field.

(b). Easy removal of the electronic cartridge containing the fuzing and firing equipment must be provided.

(c). Accessibility must be provided for insertion or extraction of the nuclear material by handling a minimum number of relatively small and lightweight components.

(d). The vibration transmitted from the case to the internal electrical components must be kept to a minimum.

(e). All case openings must be sealed with internal gaskets.

(2). Discussion, Tests, and Calculations

To provide sufficient strength for mounting the tail fins and the antennas as well as for supplying the necessary handling, weather, and fragment protection for the components, the major portion of the outer case is made of 3/8-inch mild steel. Since the front and rear of the bomb are protected by the strike aircraft structure, they do not require as much fragment protection; hence the tail cone of the rear case is 1/4-inch mild steel; the antenna noseplate is cast aluminum alloy; and the rear cover plate is 1/2-inch aluminum alloy.

Strength tests and calculations[1,2] indicate that the mechanical strength of the outer case is adequate (Ref SMD-489, Stress Test on 1/4-inch and 1/8-inch Mk IV Cone). No case damage during the normal handling and flight of 106 units has been noted. (43 of these were the later models with 1/4-inch tail cones.) One bomb with dummy internal weights was accidentally dropped from a B-29 bomb bay onto a concrete runway. The only resulting damage to the case was flattening of the split band and failure of the bolts attaching the rear case to the dummy weights. After the dent was removed from the split band, all components of the case were reusable.

A suitable ballistic contour has been achieved for the bomb as discussed under Section D, page 40 . A clean outer contour is maintained by using cavity-type antennas in the nose, a recessed lug, and flush-mounted safing plugs and pull-out plugs.

Case vibrations induced by the fins must be transmitted through the damping mass of the sphere before reaching the cartridge, which is cantilevered from the rear of the sphere. Tests which have been conducted indicate that the magnitude of vibration to which any electrical component of the cartridge will be subjected is probably less than one half that in the outer case at the base of the fins.[5]

Gasket-type sealing is provided for all openings in the outer case; thus the case serves as a container for the protection of internal components against moisture. Experience gained from long-term storage will determine whether the sealing is sufficient to allow long-term, high-humidity storage without the use of an external sealed container. Leakage tests that have been conducted to date indicate that adequate sealing exists for all operational purposes. However, inasmuch as considerable difficulty was experienced in initial procurement and quality control of inflated-type split-band gaskets, work is in progress to improve this gasket.

(E). ELECTRONIC CARTRIDGE

(1). Functional Use and Design Requirements

The cartridge was designed to contain all of the fuzing and firing components (Figs. 13 and 14) excepting those which must necessarily have connections directly at the skin of the bomb for external access and/or proper function. The specific items excluded are the antennas for the Archie sets, the receptacles for the safety plugs, and the receptacles for the pull-out plugs. In order to make plug-in connection to the detonator circuits possible, the distribution and cable compensation system was split from the rest of the X-Unit at the gap output in such a manner as to make connection by spring fingers when the cartridge is fastened into place. The distribution and cable compensation system is fastened to the sphere assembly, and the X-Unit is located on the front of the cartridge.

Vibration has been minimized by mounting the entire cartridge structure on the sphere assembly to damp out the vibration from the outer case. This practically dictated that the shape of the cartridge be cylindrical for greatest strength and most effective mounting.

The entire cartridge is easily removable for testing or replacement. The placement of parts on the cartridge permits all routine field tests to be made without removal of any of the components from the main structure. Components such as Archies and baro switches which frequently have to be modified or adjusted in the field under different tactical conditions, are easily removable without major disassembly.

Relatively few connections need to be made to complete the electrical hookup after the cartridge has been fastened into place, and these are easily and quickly accomplished. They include the four antenna cables for the Archies, the two safing-plug cables, the two pull-out cables, and the pull-out wire harness. No manifold pressure connections for the baro switches are required for this bomb, since the baro switches operate from the internal pressure of the bomb.

(2). Tests, Calculations, and Discussion

Preliminary vibration tests on a completely assembled cartridge indicated that it was not sufficiently rigid structurally. Components mounted on the free end of the cantilever experienced accelerations of several times the input to the shake table.

The cartridge case was redesigned, and the Archies were mounted for vibration isolation.[10]

Tests on the final cartridge[11] showed that the cartridge structure will withstand constant amplitude vibration from 10 to 55 cps with an acceleration of 10 g at 55 cps; the magnification ratio of the cartridge structure has been decreased considerably, and the Archie assembly has been effectively isolated from vibration.

Calculations indicate that the cartridge case and attachments of the individual components will withstand a 10-g vibratory load factor.[1]

The maximum vibration recorded for a component of the cartridge during drop tests was 1.73 g at 240 cps.[5] The amplitude of vibration for most of the drops was so small that actual values could not be obtained.

(3). Comparison With Mk III Mod 0 and Mod 1

Item	Mk IV	Mk III
Mounting of Components	All electrical components except the Archie antennas and firing distribution system are mounted on a plug-in cartridge case. The entire cartridge case is mounted on a sphere to damp out the vibration from the outer case and is easily removable for testing.	Mod 0: Firing set is mounted on the forward cone which is attached to the sphere. The auxiliary equipment for the firing set mounts on the flat plate (A-plate) attached to the forward ellipsoid. Fuzing equipment is mounted on the flat plate (C-plate) which is attached to the rear cone. The rear cone is attached to the sphere. All components except those on the A-plate are mounted on the sphere to damp out vibration from the outer case. Mod 1: Same type of mounting as Mod 0, except that the A-plate does not exist in this model.

Item	Mk IV	Mk III
High-Voltage to Detonator	Connections to detonator are made by bayonet-type pressure connectors. All detonator cables terminate in a distributor flange mounted on the sphere. The distributor flange is the receptacle into which the fuzing and firing cartridge fits after assembly to the bomb. The detonator circuits are automatically completed to the X-Unit by spring fingers when the cartridge is inserted. NOTE: This makes it possible for the first time to have detonator wiring done before installation of the firing set, and allows the fuzing and firing set to be removed from the bomb without a major disassembly.	Mod 0: Connection to detonator made by crimping coaxial cable to detonator lead. All detonator cables terminate at the X-Unit in spark-plug connectors; all calbes must be attached to the X-Unit before any of them can be attached to the detonators. Mod 1: Connection to the detonator is same as Mk IV. All detonator cables terminate at the X-Unit load rings in a preformed, removable harness which must be attached to the X-Unit before assembly. The X-Unit must be installed before the detonator connections can be made.

SECRET

[redacted]

b(3)
DoE

The mechanical specifications for this set require ability to operate under defined conditions of vibration, temperature, pressure, and humidity. The vibration specifications require vibration cycling from 10 to 55 cycles per second in one minute, with a total displacement of 0.06 inch for 45 minutes along each of the three major axes. The temperature specifications require operability of the set over the range from -22°F to +149°F. The pressure specifications require operation of the set in a normal manner at pressures as low as 7.0 psi (approximately 19,000 feet altitude). The humidity specifications require operability at humidities from 80 to 90 per cent RH at 79°F, approximately.

The X-Unit is armed by a network of clock-operated switches set to operate approximately 15 seconds after the pull-out of the arming wires. These arming wires are pulled as the bomb drops away from the plane.

b(3)
DoE

[redacted] This assembly differs from the Clock-Bank Assembly used in the Mk III Mod 1 only in the orientation of the connectors.

The Clock Assembly, housed in a Fiberglas laminate shell which serves as a heat insulator, is recessed into a central compartment of the Junction Box. The mechanism is maintained at proper operating temperature by two thermostatically controlled heater strips which are connected to the plane's power source through the FTB. Each heater strip and thermostat forms an independent heating device which cuts in at 80°F and out at 100°F.

5(3)
DOE

[redacted]

(b). Fuzing System

The fuzing system uses the same general components as were used in the Mk III Mod 1 bomb, but these components are remounted to conform with the cartridge design concepts. The fuzing system in the Mk IV Mod 0 bomb includes four Archies, six baro switches, two relay networks, and one (slot) antenna noseplate. The Archie is the same modified tail-warning radar set, the APS-13, used as the basic fuze in previous atomic bombs. The relay networks are so arranged that any two Archie output signals will operate both relay networks. Each relay network is in itself capable of firing both channels of the X-Unit.

In order to protect the Archie sets from damage due to shock and vibration, they are placed on vibration isolation mounts in the Cartridge structure.

The antenna system consists of four cavity-backed slot antennas mounted symmetrically on the front noseplate. The flush-mounting slot antenna is superior from an aerodynamic and handling standpoint to the Yagi-type antenna used on previous bombs. Electrically, the slot antenna has the desirable characteristics of broad band, low-voltage standing wave ratio (1.5 or less in the normal operating range),

suitable radiation pattern, and gain comparable to the former Yagi antenna. The noseplate assembly weighs 62 pounds. A design is now under development that will reduce this weight to approximately 15 pounds.

The baro switches are the same (BS-4 and BS-5) as those used in previous bombs and have the same function.

In the Mk IV Mod 0 weapon the pressure that actuates the baro switches is obtained by a flow of air into the interior of the bomb through six 3/8-inch ports near the nose. Since the bomb case serves as a manifold, no hose connections to the baro switches are necessary. The pressure drop across the ports produces nearly ambient pressure inside the bomb

(c). Junction Box

Excepting the antenna cables, all fuzing and firing system interconnections are made through the Junction Box. The use of the Junction Box makes it possible to disconnect any of the major subassemblies for replacement or modification without a major disassembly of the cartridge. The Junction Box contains the Archie integrating capacitors, the relay networks, the power fuses, and the pull-out switches. The pull-out switches are so mounted that pull-out wires can be inserted without removal of the Junction Box cover.

(d). Power Supply

The power supply for the Mk IV Mod 0 bomb consists of two independent banks of 30-volt lead-acid batteries contained in one heated enclosure. It is identical to that used in the Mk III Mod 1 bomb. The batteries, designated ER-12-10, are markedly superior to the NT-6 batteries used in the Mk III Mod 0 bomb. They have a longer shelf life in a charged condition, greater mechanical ruggedness, and require simpler preparation and installation procedures during weapon assembly operations.

(e). Safety Features

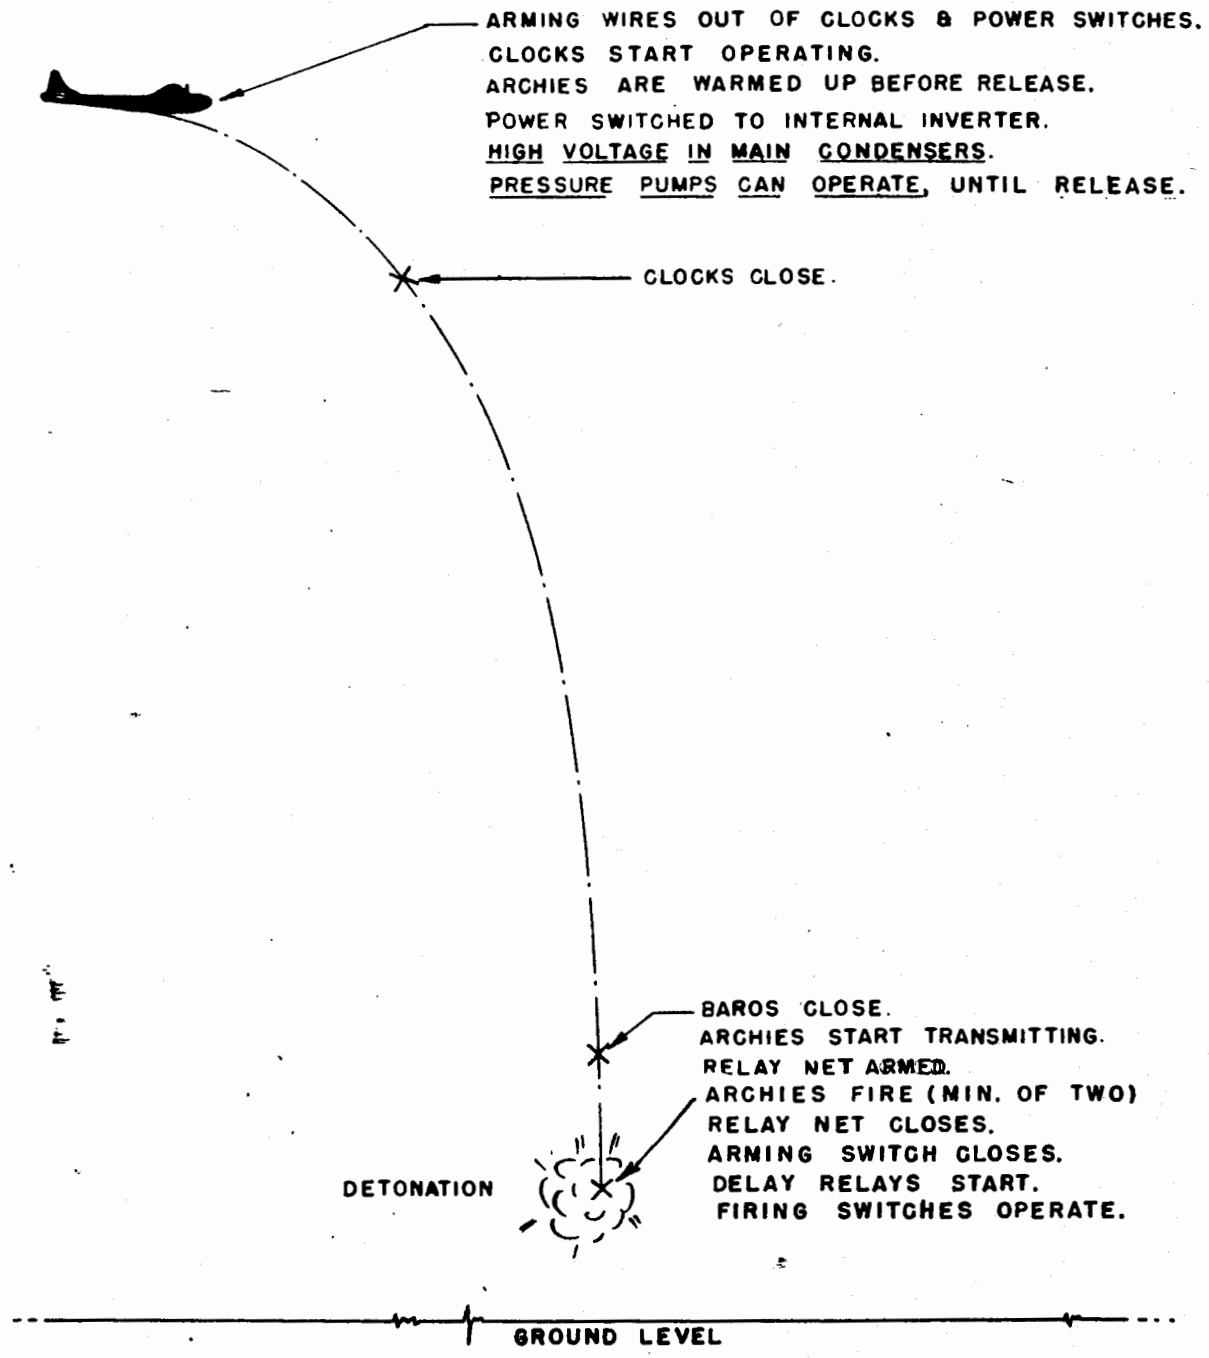
Adequate safety features are included in the design of the electrical system to prevent premature detonation under all predictable circumstances from the time of assembly until the baro switches close (normally a few seconds before detonation altitude).

Protection from the time of assembly until the firing plugs are inserted is afforded by safing plugs in the nose of the bomb. These safing plugs open the power lines to the firing set, and, in addition, short-circuit the input lines to the firing set. Protection during the remainder of the time the bomb is in the plane is afforded by a bank of clock-operated switches which provide an open circuit to the firing set, and by pull-out switches which provide open circuits from the relay network outputs to the firing switches.

Protection from time of release until the bomb is out of fuze range of the strike aircraft is afforded by the X-Unit arming clocks and barometric switches.

In the event of premature baro-switch closure, the arming clocks will prevent the X-Unit from firing should the radar fuze range on the plane. Normally, the baro switches prevent the radar fuze from operating during this period.

Protection against premature detonation after operation of the clock switches is afforded solely by the baro switches. They minimize chances of premature fuze operation due to malfunction of equipment and radar countermeasures.

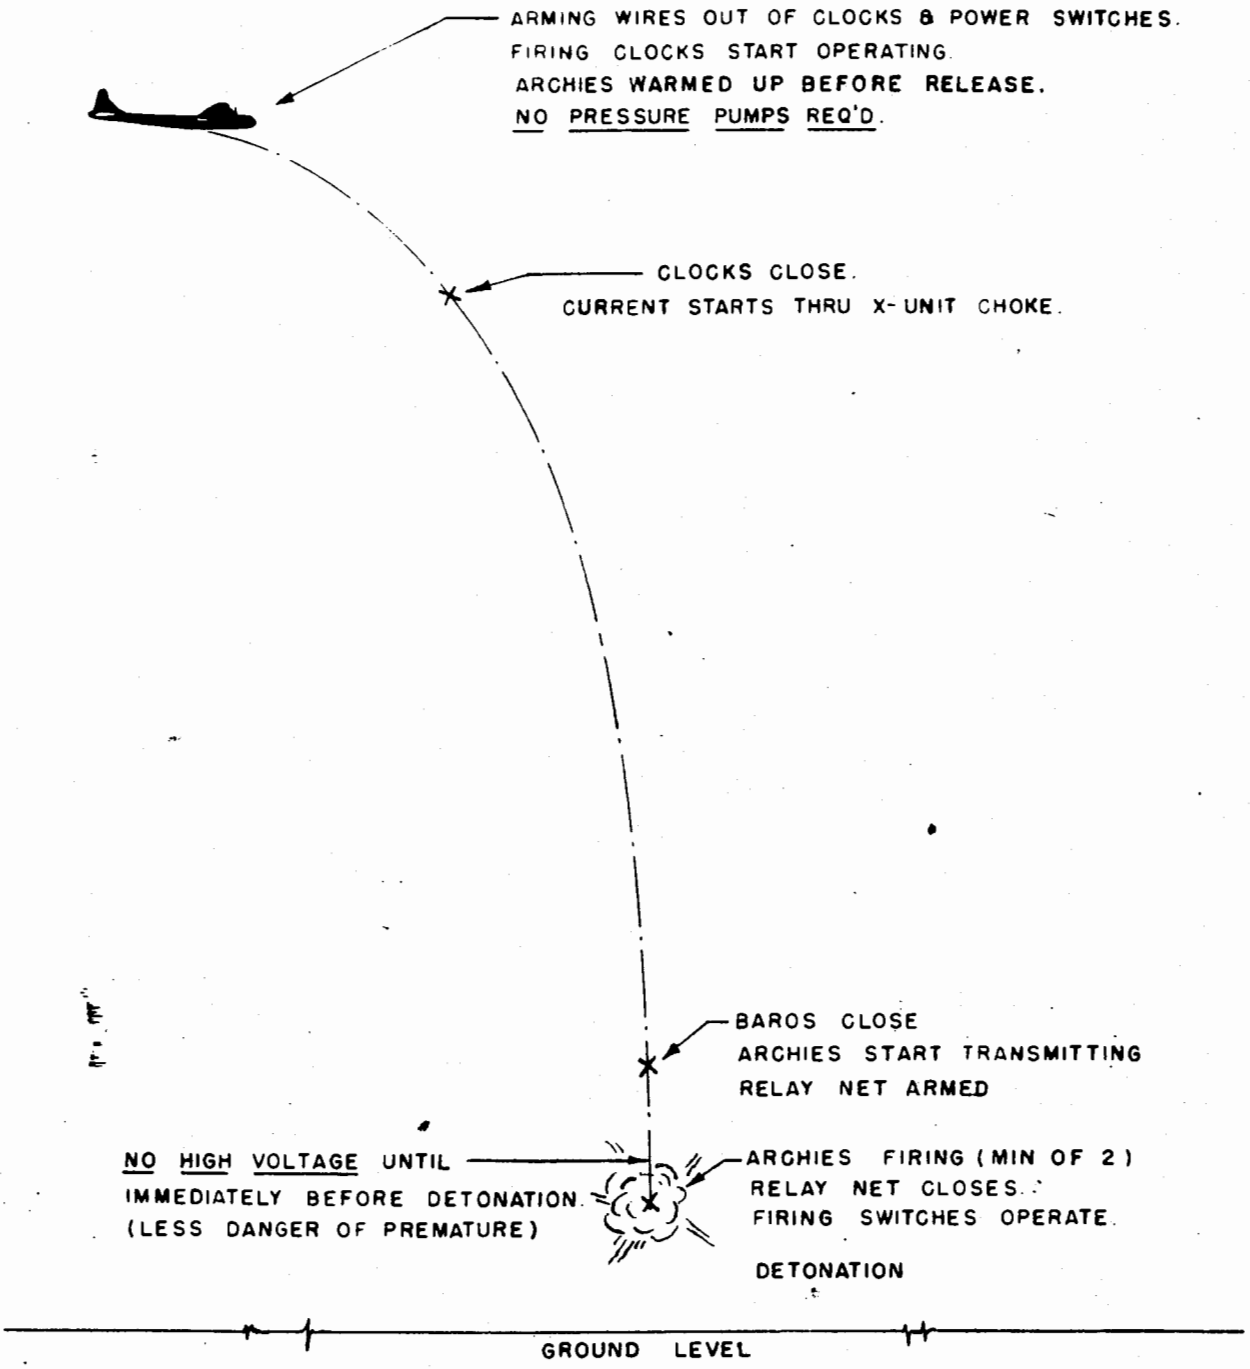


(f). Comparison of Drop Sequence of the Mk III Mod 0 and the Mk IV

Operating phenomena after release are provided in Figures 17 and 18. There is no significant difference in this respect between the Mk III Mod 1 and the Mk IV.

(2). Tests, Calculations, and Discussion

(a). Firing System



The X-Unit Mk IV Mod 5 has successfully operated under all conditions of temperature, pressure, vibration, and humidity mentioned above on page 58[12,13].

WITH THE MK. II X-UNIT
(MK. III MOD. 0 ATOMIC BOMB)

FIGURE NO. 17

UNCLASSIFIED

DROP SEQUENCE FOR THE MK IV, MOD 0 ATOMIC BOMB

UNCLASSIFIED

FIGURE NO. 18

Several pulse transformers were tested thousands of times with 1.5 watt-seconds of energy; 1.2 watt-seconds is typical of X-Unit usage. No failures resulted.[14]

Firing Switch Vibration Tests. -- The firing switch, in its enclosure, was vibrated at 10 g from 30 to 200 cps.[15] Trouble with contact chatter was encountered at higher frequencies, but operation was normal at accelerations well above those met with in drop tests.

X-Unit Condenser. -- Condensers have passed a 17-kilovolt high-potential test at temperatures as low as -70°F.[16]

[redacted]

These results have been verified at Los Alamos by GMX-7 through an explosive mixture similar to that used in the 1E20 detonator (Ref GMX-7-30, Mk IV Mod 5 X-Unit Firing Tests, August 16, 1949).

Clocks. -- The modified M-111A2 fuze is capable of withstanding a vibration of 10 g at 10 to 55 cps in three planes for 45 minutes. Operation was not affected by exposure to 120°F, 98 to 100 per cent RH for 48 hours, with subsequent lowering of temperature in decrements of 5° per minute to 25°F. The main weakness of this clock is that it is neither rewindable nor resettable without special procedures, including the taking of X-ray pictures. This, coupled with a total life of approximately five operations, prohibits field testing and makes operational testing by the Road Department impracticable. This timing device is not suited to long-term storage because (a) it must be stored in wound condition, which may result in a weakening of the untempered main spring; (b) the lubricant becomes viscous during long-term storage; and (c) not all parts are corrosion resistant.

(b). Fuzing System

Archie Tests. -- Normally-mounted Archies were vibrated in a cartridge for 45 minutes in the two most severe planes. Maximum acceleration at the base of the cartridge was 10 g at 55 cps. No mechanical failures occurred, and the Archies were electrically operable at the conclusion of the tests.[11]

(3). Comparison With Mk III Mod 0 and Mod 1 FM

Item	Mk IV	Mk III
(a). X-Unit Note: Mk IV X-Unit is essentially a re-packaged version of the X-Unit used in the Mk III Mod 1 bomb. The clock enclosure and the battery box have been removed from the X-Unit and located elsewhere on the cartridge.	Charges a condenser from 30-v d-c source to high voltage by means of a resonant charging circuit.	Charges condenser to high voltage from 30-v d-c source by means of 400-cycle inverter, step-up transformer and rectifier.
	Energy to fire detonators stored in magnetic field prior to operation of firing switch.	Energy to fire detonators is stored in condenser bank charged to high voltage before operation of firing switch.
The unit has been designed to save weight and bulk. The wiring of the unit has been considerably simplified.	The X-Unit is armed by two banks of clock-actuated switches, started by pull-out wires, one bank per circuit, two per X-Unit.	Iris-type arming switch is actuated by relay net. 12-v d-c winding is operated at 30-v d-c for rapid action and positive hold-down. Two switches are provided per circuit, four switches per X-Unit.
The remarks in the "Mk III" column pertaining to the X-Unit refer only to the Mk II X-Unit that is used in the Mk III Mod 0 FM unless specifically mentioned otherwise.	The firing switch is a high-speed switch operated by the impact of a rotor. This provides nearly instantaneous opening of the switch to cause the sharp voltage rise that is desired in the firing condensers. It is operated by Archies after gate formation. Delay Relay is not required. No interlock is required because the arming switch must be closed before any power is available to the choke, which is the only source of high potential. Consequently, if the firing switch did operate prematurely for any reason (highly improbable), no firing would result as long as the arming switch was not first actuated.	Firing switches, two per X-Unit, one per each circuit, are operated by Delay Relays which are started by Archie relay net. The Relays prevent too early a closure. An interlock (electrical) prevents the closure of firing switch before arming.

SECRET
UNCLASSIFIED

Item	Mk IV	Mk III
(a). X-Unit	The Mk IV gaps have a radioactively stabilized breakdown voltage; hence are more uniform in characteristics than those in the Mk II X-Unit. These stabilized gaps are used as voltage sensitive switches to fire detonators automatically when sufficient voltage exists. [redacted] b(3) DoE	The Mk II X-Unit gaps do not require special stabilization of the breakdown voltage, since their breakdown is normally forced by a trigger pulse applied simultaneously to a special electrode in each gap when a firing switch operates. [redacted] This, plus a bias stabilization system for the trigger electrodes, insures that no gap will break down without a normal firing switch operation. b(3) DoE
	Premature gap breakdown is not possible as previously explained under firing switch above. The high potential needed for firing the detonators is not present until the firing switch is operated by the final Archie signal. Firing condensers are shorted and grounded until the firing switch opens.	Premature gap breakdown is unlikely as indicated in the preceding paragraph. Measures have been taken to insure that even an improbable premature gap failure will not fire the detonators. An arming switch for each gap opens the circuit to the detonators, and also grounds the input to the detonator cables. In addition an electrical interlock between the arming and firing switches prevents triggering of the gaps prematurely.

[redacted]

UNCLASSIFIED

UNCLASSIFIED

Item	Mk IV	Mk III
(a). X-Unit	Because high voltages are not present at high altitudes, no pressurization of the X-Unit is required to prevent flash-overs. The whole system provides safety through simple circuitry.	The Mk II X-Unit case must be pressurized in the bomb bay and during the drop to prevent flash-over of high voltage at high altitude. Unit has high voltage present both in the airplane and during the drop.
	Only moving parts are the magnetically operated firing switches (2).	Moving parts are the magnetically operated arming switches (4) and firing switches (2).
	Open framework construction.	Unit sealed and pressurized.
	Very simple circuitry, containing only essential operating elements.	Circuitry quite involved.
	Weight of X-Unit 335 lbs approximately.	Mod 0 FM - 300 lbs approximately Mod 1 FM - 700 lbs approximately (with full batteries).
(b). Archies	Either X-Unit spark-gap switch fires all detonators.	Each spark-gap switch fires only half of the detonators.
	Archies are antivibration mounted.	Archies are not antivibration mounted.
(c). Barometric Switches	Same as used in Mk III.	BS-4 and BS-5.
(d). Barometric Switch Pressure System	Baros are open to the interior of the weapon. Pressure for operation of the baros is obtained by a flow of air through six port openings and desiccators located approximately 1/2" aft of the flat nose of the weapon.	Baros are connected to an annular manifold which is in turn connected to eight holes located about 30 inches aft of the maximum diameter of the bomb.

SECRET UNCLASSIFIED
SECRET UNCLASSIFIED

Item	Mk IV	Mk III
(e). Junction Box	Archie outputs are connected to two hermetically sealed relay networks. Each relay net output is connected to one firing switch.	Archie outputs are connected to a single relay network with a common output. This common output is connected to both firing switches.
	Pull-out switches can be armed with pull-out wires without removing the Junction Box cover.	The Junction Box cover must be removed to allow arming of the pull-out switches with pull-out wires.
(f). Pull-out Wires	A single pull-out wire seal assembly, fastened by three screws, is used to pass the ten pull-out wires through the rear case.	Five pull-out wire assemblies, each fastened with four screws, are used to pass the ten pull-out wires through the ellipsoids.
(g). Pull-out Cables	2 required for monitoring of electrical equipment during flight.	Mod 0 FM - 6 required. Mod 1 FM - 3 required.
(h). Archie Antennas	Uses 4 slot-type antennas flush-mounted on a single flat plate which serves as the noseplate for the weapon.	Uses 4 Yagi-type antennas that are mounted on and protrude from the ellipsoids. To prevent mechanical damage to the antennas and for security reasons, it is desirable to mount them after the weapon is loaded into airplane.
(i). X-Unit Clock Bank	Same as Mk III, but mounted in Junction Box assembly.	Mod 0 - None used. Mod 1 - 8 M-127 flare fuze clocks placed in one heated enclosure, 4 clocks per bank, 2 banks. Mounted in X-Unit assembly.

(J). NUCLEAR COMPONENTS

(1). Functional Use and Design Requirements

The purpose of the nuclear components is to release rapidly a large quantity of energy through the fissioning of a core of U-235 and/or Pu. The energy is released as a result of the rapid rise of the neutron population in a highly compressed supercritical system of fissionable material surrounded by a neutron reflector or tamper. Since the

[redacted]

energy release which causes the active material and tamper to expand and thus become a subcritical system.

The basic design which determines the size and arrangement of the various nuclear components is the product of a large number of calculations and experiments which consider, among other things, the hydrodynamics of the imploding system, the neutron properties of the active material and the tamper, and the nuclear safety problems associated with handling the fissionable material.

The engineering design must primarily consider (1) maintenance of symmetry in the assembled nuclear system with a minimum of cavities, protuberances or other perturbations; (2) fabrication problems associated with the rather uncommon materials used: and (3) requirements for ease of insertion and removal of the nuclear capsule.

(2). Tests, Calculations, and Discussion

[redacted]

(III). BOMB ASSEMBLY AND TEST EQUIPMENT

(A). Functional Use, Design Requirements, and Discussion

The equipment required for handling, assembling, and testing the Mk IV Mod 0 FM is divided into Types 1, 1A, 2, 3, and 4 in such a manner that all necessary bomb operations can be efficiently performed. Types 1 and 1A, 2, 3, and 4 have been given contracting names, ie, "kits," "lots," "groups," and "sets," respectively.

(1). Type 1 - Field Equipment - Kits. -- Type 1 equipment is divided into kits which contain the tools and equipment required by assembly teams for field assembly and field testing of the bomb and minor maintenance of test equipment. These kits are the following:

(a). Cartridge Test Kit - 40A

The Cartridge Test Kit contains all test equipment, tools and auxiliary equipment required for the complete testing of the fuzing and firing components of the bomb. The major items in this kit are a Flight Test Box, Delta Timer, Peak-Reading Voltmeter, Archie Test Panel, Baro Switch Tester, Junction Box Tester, Flight Circuit Tester, High Potential Tester, Unit Tester, Meter Calibrator, and Cartridge Dolly.

(a). Lot 40 I

The contents of this lot have not yet been definitely determined, but it will contain items such as a dispersal cradle for supporting the bomb prior to loading into the strike aircraft, and a Flight Test Box which is installed in the strike aircraft for flight check of the bomb.

(b). Lot 40 T

[redacted] b(3) DOE

(4). Type 3 - Base Equipment - Groups. -- Type 3 equipment is divided into groups which contain tools and equipment required at bases for major disassembly, long-term surveillance, and major maintenance. Base equipment will not be used for field assemblies. The various groups are the following: Group K: Canning; Group R: Nuclear; Group U: Instrument Repair; Group V: Electrical; and Group N: Mechanical.

(5). Type 4 - AFSWP Support - Sets. -- Type 4 equipment is divided into sets which contain items of support equipment for the military field organization such as material for shelter, power, disaster cleanup, and expendable stock. It will be the responsibility of the using forces to determine and procure most of the items in these sets. The various sets are the following: Set J: Expendable Stock; Set L: Heavy Tool; Set W: Disaster; Set X: Salvage; Set Y: Building; and Set Z: Power.

(B). Comparison with Mk III Mod 0 Bomb

The following list shows the comparative number of items required for assembly and testing. Owing to changes in kit philosophy the number of items may change, but their relationship will remain approximately the same.

	Mk IV		Mk III Mod 0	
	Total Items	Special Items	Total Items	Special Items

Miscellaneous Equipment				
(a). Expendable Set J (b). Heavy Tool Set L (c). Disaster Set W (d). Salvage Set X (e). Building Set Y (f). Power Set Z	Little change from the kits already established for the Mk III will be required.			

(IV). SUMMARY

The Mk IV Mod 0 FM is an implosion-type atomic bomb based upon the same basic nuclear fission principles as the Mk III FM. It incorporates an improved fuzing and firing circuitry over that in the Mk III Mod 0 weapon and the same basic circuitry as that in the Mk III Mod 1 weapon. The bomb is re-engineered to provide for greater ruggedness, greater dependability, easier field techniques, and better ballistic performance than either of the Mk III versions.

The ballistic design is the result of over 100 full-scale and half-scale drop tests, including 29 drops of the final design in addition to wind tunnel and range-fired 20-mm model tests which showed good correlation to the drop tests. Values of pitch and yaw for B-29 conditions are less than 6 degrees maximum included angle, and dispersions due to the bomb itself are less than one fourth of those of the Mk III FM.

The basic elements of the fuzing system (baro switches, Archies, and clocks) have not been changed at this time, but details of the Junction Box, including the relays and pull-out switches, have been redesigned and improved. The mounting of all components has been improved to minimize the possibility of damage or malfunction. The firing set (X-Unit) has been completely re-engineered for compactness and ruggedness. All electronic equipment has been tested in the laboratory and these tests have been supplemented by 30 functional drop tests.

The field assembly and electrical checking operations that will be required on the bomb have been minimized:

[redacted] b(3) DOE

(V). CONCLUSIONS AND RECOMMENDATIONS

It is concluded that the Mk IV Mod 0 FM implosion-type atomic bomb is an improvement over its predecessors, the Mk III Mod 0 FM and the Mk III Mod 1 FM, in the following respects:

(1). It requires less time, fewer men, and less auxiliary equipment in the field to prepare the bomb for delivery.

(2). It adapts itself to safer delivery tactics inasmuch as (a) the nuclear material may be inserted after the strike aircraft is airborne, and (b) high voltage is not present in the firing circuit until the firing switch is actuated (this is also true of the Mk III Mod 1 FM).

(3). It contains many improved components specifically designed or arranged to operate and withstand storage under stringent environmental conditions.

(4). It has improved ballistic stability and accuracy.

On the basis of these conclusions it is recommended

(1). That this weapon be produced and stockpiled as a part of the national defense program;

(2). That it replace the Mk III weapons now in stockpile;

(3). That laboratory and field investigations of all components be continued in an effort to establish more firmly the reliability and safety factors as well as the limiting environmental conditions of operability; and

(4). That a continued program of component development be pursued for the purpose of incorporating desirable modifications into stockpile weapons in the interest of military effectiveness.

(VI). FUTURE PROGRAMS FOR THE MK IV FM

The report thus far has dealt with the description and evaluation of the Mk IV Mod 0 FM weapon as it is going into stockpile. Inasmuch as progress in the field of weapon design is made a step at a time, it is planned to continue a development program on this weapon to incorporate new component improvements and features now thought to be desirable. These fall into two main groups, each of which may require a Mod change of the bomb.

(A). Lightweight Outer Case

[redacted] b(3) DOE

be possible. ~~This change~~ in case design will sacrifice all protection of the unit from low-velocity fragments, but the weight saving will materially reduce take-off hazards and permit an increase in aircraft range or speed. It will probably bring about fairly radical changes in handling techniques and equipment. This design program is now under way.

(B). New Electronic Cartridge

The second program encompasses the redesign of the electronic cartridge to provide a more reliable fuzing system. Several radar fuze devices and a new baro switch are under development at the present time. (It is planned to incorporate selected ones of these individual components into a new cartridge.)

One feature of this new cartridge will be in-flight setting of the fuzing system (specifically, of baro switches and radar units).

New clock timers and new baro switches are being developed to replace these present items in the Mk IV Mod 0 should it be judged economically and tactically desirable when the development is complete. Work is in progress to develop a lightweight and quickly detachable antenna nose-plate and sphere trap door to facilitate in-flight nuclear insertion. A new plug-in type of delay line has been developed for Archie. This modification will reduce the possibility of multiple gating, allow easier range modifications, and provide a higher maximum range setting. It is planned to replace the present Archies with the new unit, pending laboratory and drop tests.

Three other programs are being carried forward as essential improvements to the Mk IV Mod 0 to be included when the need for them is firmly established:

(1). Improvements to the present baro system.

(2). Improvements of the present split-band gasket.

(3). Solutions to the problem of the sticking of the HE trap-door charges.

SECRET

With the approach of World War II, both the German and Russian rocket programs became enveloped in secrecy. The next reliable information was received by the West when the Nazi V-1's (and later the V-2's) began to bombard London. This effort was not small. Dr. Walter R. Dornberger, who was in charge of the V-2 program and retained meticulous records of the activity, disclosed after the war that 5085 V-2's were build and 3578 launched.[1] After the end of the European phase of World War II, many German rocketry experts were captured by the Russians, forcibly removed to Soviet territory along with the tools and equipment of their trade, and their lore and experience added to that of the Soviets.

The United States had used small solid-propellant rockets in the Pacific phase of the war, with ship-launched rockets being employed as "softening-up" devices prior to Marine landings on Japanese-held islands, and hand-held Bazookas being used in the attack of enemy strongpoints. No heavy boosters or liquid-motor rockets had been developed, however, and the field of use of these devices was felt to be small.

Postwar experimentation at the White Sands Proving Ground in New Mexico with a captured German V-2 brought the United States to the realization that this liquid-motor device, capable of a velocity of 3600 miles per hour and a range of 100 miles, was worth developing. The Air Force established the Rand (research and development) Project under the aegis of Douglas Aircraft Company in early 1946, and the first study produced by this group described a satellite vehicle using liquid fuel and multistage rockets. Dr. Theodore von Karman, one of the organizers of the Rand Project, subsequently surveyed the state of the art in Europe and came to the conclusion that the best method of increasing the range of the V-2 was to provide a set of wings for the missile. The United States elected to follow this course, which led to consideration of pilotless bombers flying at relatively low altitudes, and development of air-breathing missiles rather than pure rockets, which were self-contained and could operate outside the atmosphere.

The success of the Germans in developing the V-missiles and the later appearance of the atomic bomb led observers to believe that a quick "marriage" of the two would follow and inaugurate an era of "pushbutton warfare." Such estimates failed to evaluate properly the complexities attendant on the development of each device and the relatively primitive state of each.[2] Lacking were such factors as reliable guidance systems, competent propulsion systems, shock-resistant warheads, and the high-quality, or "clean-room," type of manufacturing facilities yet to be developed. However, early military characteristics for an air-to-ground missile had been proposed by the Army Air Force October 19, 1945, envisioning a warhead 60 inches in diameter, 130 inches long, and 11,000 pounds in weight (in obvious reference to the Fat Man bomb), although missiles capable of carrying a warhead of this size and weight would not be available for several years.

In March 1946 the Army Air Force directed the Air Materiel Command to develop an experimental missile, and this project was given a code name of MASTIFF.[3] At the time, little information regarding MASTIFF was made available to those working on the atomic bomb, but in one of his last actions, December 12, 1946, as head of the Manhattan Engineer District and prior to AEC assumption of control, Brig. Gen. Leslie R. Groves informed the Los Alamos Scientific Laboratory concerning the project, and stated that it envisaged installation of an atomic warhead in an air-to-ground guided missile.

This information was referred to the Z Division on January 10, 1947, with a request that preliminary analysis be made, but that any sizable amount of development work be deferred until later in the year when the work load was expected to taper off.[4] Subsequently, little was done on the project in either AEC or military circles beyond a general study that contemplated use of a plane-launched drone which would glide 300 miles to a target at a speed of 300 miles per hour. However, a drone with this speed was felt to be highly vulnerable to antiaircraft fire, and the existing scarcity of nuclear material, together with the inaccuracy of drone control systems, caused apprehension that an atomic weapon might be used to bomb some unoccupied field. In mid-1947, missile development for the MASTIFF project

was assigned to Bell Aircraft Company, and was rescheduled as a long-range project to be preceded by SHRIKE, a 100-mile-range supersonic missile on which Bell had been intermittently engaged since 1945.

Subsequently, budget cuts in the 1946-1949 period reduced military participation in missile work. A 3-year period of recuperation, starting in 1950 and caused by the Korean War, partially restored financial support, but another retrenchment was made in 1953. It was not until 1956 that the missile program was consistently funded. Due to this early uncertainty, the Military gave preference to those devices which promised to reach production with the least expenditure of time and money. This generally relegated long-range missiles (which were those best suited to carrying atomic warheads) to low-priority status during the period.

The Division of Military Application notified the Military Liaison Committee, April 29, 1949, that some guided missiles being developed might reach a stage in the not too distant future where the desirability of employing them in conjunction with an atomic warhead should be considered.

This led to the establishment, June 21, 1949, of an Ad Hoc Committee, to consider the general problems of developing atomic warheads for guided missiles, and which reported to the Secretary for Defense. This Committee consisted of Lt. Gen. J. E. Hull, Director of the Air Force Weapons System Evaluation Group; Dr. F. L. Hovde, President of Purdue University; and Dr. N. E. Bradbury, Director of the Los Alamos Scientific Laboratory. This committee was to assess the possibilities for developing, within the next 5 to 10 years, guided missiles that might carry atomic warheads, and analyze the possible application of existing atomic weapons technology to the development of such warheads.[5]

The Ad Hoc Committee subsequently reported that Service requirements for a guided missile with an atomic warhead could be met within a reasonable time. It was concluded that four missiles could be adapted, with reasonable technical effort, to carry atomic warheads. These were the HERMES A-3 of

Subsequently, separate conferences were held with the three Services and Sandia Base representatives of the Armed Forces Special Weapons Project. These conferences explored the details of weapon-missile relationships, placing emphasis on Mk 5 and Mk 8 Warheads.

The Sandia Weapons Development Board provided a common forum for designer and user of atomic weapons and, in a meeting June 21, 1950, agreed to accept responsibility for coordinating guided-missile and atomic-warhead development. The Board proposed that a strong missile subcommittee be formed, but temporarily deferred appointments to this subcommittee, pending arrival of new officer assignments at Sandia and Kirtland Air Force Bases.[8]

The Division of Military Application had noted, in a letter dated June 14, 1950, that some controversy had arisen over the subject of responsibility for warhead fuzing. Army Ordnance had assumed that the Atomic Energy Commission would handle fuze development, but the AEC felt that the fuze characteristics would be strongly affected by missile operation and environment, and therefore the fuze should be designed by the missile agency.[9]

This subject was discussed in the June 21, 1950, meeting of the Sandia Weapons Development Board. One proposal was that the AEC provide funds for fuze development and retain nominal control of the project, with the work being accomplished by Army Ordnance or missile contractor. The Board in general felt that the missile was simply a carrier, that it replaced the aircraft carrying bombs, and that the fuze was part of warhead development. However, it was recognized that there was no easily defined line of demarcation between warhead and missile (such as between bomb and bomber), and the eventual ruling was that a decision on fuzing design responsibility would be made for each individual missile-warhead project. The Board proposed that AEC budget for fuzing development costs in the immediate future and that these funds be allocated to the military or AEC contractor assigned responsibility for fuze development.

On October 1, 1950, Project E, Department 1270, was established at Sandia Corporation under the jurisdiction of the Director of Engineering. The task of this Department was to study the problems of integrating atomic warheads with guided missiles. A year later, this organization evolved into Engineering II, the guided-missile Directorate.

The Division of Military Application agreed, October 10, 1950, that the AEC would accept budgetary responsibility for all guided-missile warhead fuzing with coordination of each fuze development program being subject to recommendations of the Sandia Weapons Development Board, and that requirements for an air-burst gun-type warhead were deleted.[10]

A Guided Missiles Committee of the Sandia Weapons Development Board was appointed and initially met October 16, 1950. The committee discussed accelerations, vibrations, and general environmental conditions which would be experienced by guided missiles, and concluded that these could be withstood by atomic warheads. The Committee proposed that a separate Ad Hoc Working Group be established for each missile-warhead marriage program, with the group proposing technical solutions to problems encountered in the programs.[11] The Board approved this suggestion, and these Ad Hoc Groups became a standard and important part of the missile program.[12]

The Committee also felt that specific fuzing systems for guided missiles would have to be developed, but that it should be initially possible to modify bomb fuzing systems.

DOE b(3)

It would be necessary to spell out carefully the relative priorities of the various programs, and the Committee felt that the current list of missiles should be considerably reduced in number. This list had been constantly changing, with the CORPORAL and SNARK being temporarily deleted, and additional versions of the HERMES, the RIGEL, NAVAHO, and TRITON being added.[13]

involved, that of ballistic (where the missile was launched upward and then fell into a target) and that of release from a carrier downward onto a target.

The Division of Military Application notified the Military Liaison Committee, January 19, 1951, that increasing requirements for various combinations of missiles and warheads had reached the point where standardization of warhead design was becoming difficult, if not impossible, to achieve. It was felt that the design of the Mk 5 and Mk 7 Warheads had progressed to the point where these warheads could be proposed for marriage with missiles and eliminate any need for alternate warheads.[16]

A nomenclature system having the prefix "XW" to identify warheads under design, similar to the "TX" identification for bombs, was authorized in mid-January 1951. This prefix was followed by the warhead identification (Mark number) and was coupled with the missile designator for complete missile-warhead nomenclature. The "X" stood for experimental, and the "W" for warhead. A typical example was: XW-5/REGULUS.[17]

Detailed design was meanwhile proceeding on the arming system. It was felt that automatic arming should be provided, which would take place only after the missile had crossed into enemy territory, and it had been proposed that the missile guidance system be used to signal this fact. However, there was such a complexity of missiles, with different guidance systems, that this was found to be impracticable. It was possible, however, to provide a system that would sense the initial missile speed, the existence of high-enough thrust for long-enough time, the attainment of sufficient altitude, and the pursuance of the correct direction. All these factors could be gaged by gyroscopes, clocks and acceleration switches, and a system could be devised to permit nuclear insertion only when all these factors had been met or exceeded. Sandia provided such a system for all missile-warhead combinations, with the gyroscope, clock, or switch shorted out when a given missile had no need to measure that particular factor.[18]

The fuze responsibility problem was again raised in the September 24, 1952, meeting of the XW-5/RASCAL Ad Hoc Working Group. Sandia and the Air Force presented opposing fuze-design proposals, and a clear-cut decision could not be reached. The problem was referred to the Guided Missiles Committee, which also could not reach unanimous decision, and it was in turn referred to the Special Weapons Development Board, where it was thoroughly discussed in a meeting November 12, 1952. The majority of the Board felt that Sandia should be assigned the fuzing task.

Meanwhile, the Air Force recommended to the Joint Chiefs of Staff that the Military be made responsible for all adaption-kit design (including that of the fuzing system) and that the interests of the AEC be confined to the design of the warhead proper. The Joint Chiefs of Staff endorsed this proposal and referred the decision through the Military Liaison Committee to the Division of Military Application. The DMA received this directive at almost the same time that it learned of the Board decision to assign the RASCAL fuzing responsibility to Sandia.

The Division of Military Application then reversed the decision of the Special Weapons Development Board, declaring, January 22, 1953, that basic responsibility for all guided-missile items of launcher, carrier, guidance, and fuzing would be assigned to the Military "... regardless of whether such parts are common to a standard rocket or missile or are required for use of the rocket or missile with a given atomic warhead."[22]

Subsequently, responsibilities of the Guided Missiles Committee were reviewed in the light of the above decision. It was decided to phase out this Committee and form new Joint Committees to replace the Ad Hoc Working Groups.[23] The major result of this change in policy was that the fuze-design responsibility was assigned to the missile contractor, who subsequently found that he could not produce fuzes with the proper capabilities within the time schedule, and who in turn subcontracted the fuze design back to Sandia.

Meanwhile, the Division of Military Application had issued a set of military characteristics September 11, 1951, covering an atomic warhead of the Mk 5 type for application to the MATADOR, REGULUS, HERMES, RASCAL, RIGEL, and

TRITON missiles. The warhead was not to exceed 44 inches in diameter, 77-1/2 inches in length, and 3000 pounds in weight.

DOE b3

Nonradiating fuzes were felt to be highly desirable, setting of burst height was to be possible just prior to missile launching, and preflight checks were to be of a simple accept or reject type.

DOE b1

A variety of interpretations had previously been given to definition of warhead and warhead installation, and were standardized by the Sandia Weapons Development Board December 11, 1951. The warhead was defined as the nuclear pit and capsule, high-explosive sphere, detonators, X-unit, firing switch, nuclear insertion mechanism, and all hardware and cabling pertaining to these items. The warhead installation included the warhead, arming and fuzing system, power supply, and installation hardware. The warhead installation thus might vary for different missiles, even though the same warhead was used.[25]

The XW-5 Warhead would contain a Mk 5 Bomb implosion system, a Mk 5 Firing Set with a fast-firing X-unit and switch for contact bursts, and a new linear nuclear insertion mechanism.[26] Mk 5 nuclear capsules would be

used. This would produce a warhead 44 inches in diameter and 75-1/2 inches in length with a weight of 2550 pounds, excluding power supply, arming and fuzing, and mounting hardware.[27]

The Sandia Weapons Development Board ruled that the warhead installation should not be design released until six successful tests of the warhead in the missile had been made. Missile availability dates were still largely indefinite, but it was felt that at least 9 months would be required between design release and early production.

The Mk 5 Mod 0 Warhead was design released August 1953, and production was achieved July 1954. The warhead incorporated a linear nuclear insertion mechanism, but otherwise was identical with the Mk 5 Bomb less outer case.

DoE
b(3

A Mk 5 Mod 1 Warhead was proposed for use with the RASCAL missile, incorporating dual-motor nuclear insertion mechanism, but was canceled during design, April 16, 1956.[28]

Investigation was undertaken of both forward extending pressure probes and trailing devices. It was hoped to develop a simple barometric fuze, but tests showed that the pressure pickups did not give reproducible results, and that the missile would have to travel faster than Mach 1.0 to prevent premature fuze operation.[32] A decision was made to use a baro-armed radar fuze, a modification of the fuze design of the Mk 5 Bomb.[33]

In early 1952 the Mk 5/REGULUS was given a higher priority than its Mk 8 counterpart, since there was a limitation in the number of missiles available for test flights.[34] Work was started on a contact fuze for several missiles, and successful completion of this task made it possible to provide the XW-5/REGULUS with two fuzing options; radar air burst with contact-fuze backup, and surface burst by impact crystals.

The Navy had requested that a pure barometric fuze be developed, and this was discussed in the June 27, 1952, meeting of the Ad Hoc Working Group. Sandia reported that this design would require an additional 10 months, and that it was not at all certain that such fuze would have the required accuracy. The Group, after considerable discussion, decided to approve the radar fuze for use in the REGULUS and to continue development of a barometric fuze.

The RAM Program (for REGULUS Assault Missile) was initiated by a letter from the Military Liaison Committee to the Division of Military Application August 18, 1952. This was a project to provide the capability for launching the REGULUS missile from a surface ship, guiding the missile to target, and arming and detonating the warhead by command from carrier-based fighter aircraft.[35]

The program was given a high priority in mid-February 1953, and a small number of Mk 5 Bombs were placed in standby storage April 1953, together with the hardware to convert these bombs to RAM installation, which had been renamed the REGULUS Interim Capability Program. These units were subsequently retired in mid-1954, as normal XW-5/REGULUS components became available.[36]

The launching action closed two pullout switches which applied power to the timer motors. At the end of 6 minutes' safe-separation time, the timer made power available. If the command arming signal bypass switch was closed, the nuclear capsule was now inserted; otherwise, receipt of the command nuclear-arm signal resulted in this operation. When the missile "dump" signal was received, voltage was made available to relays controlled by an arming baroswitch. In addition, these arming relays connected the radar arm circuits to the fuze baroswitch.

When the missile descended to a pressure altitude of about 20,000 feet, the arming baroswitch closed, starting the inverters and charging the X-unit. At an altitude 700 feet higher than the desired height of burst, the fuze baroswitch closed and armed the radars, which began transmitting and receiving. If both radars were operating properly, the X-unit was triggered and caused detonation when the second of the two radars ranged. If one radar failed to range at its preset altitude, detonation occurred 300 feet lower, when the fourth element in the fuze baroswitch closed. This element effectively switched the radar firing lines from a series to a parallel connection. If both radars failed to operate, an impact-fuze system triggered the X-unit.

For the RAM mission, special plugs were installed which allowed the X-unit to be charged when a command electrical arm signal was received from the control aircraft. Transmission of a second command caused the nuclear insertion mechanism to operate, and subsequent issuance of the command-fire signal detonated the warhead. The impact fuze provided a backup.

Meanwhile work had been proceeding on a barometric fuze design. Some progress was made and, in the Ad Hoc Working Group meeting October 7, 1953, it was decided that the remaining REGULUS flight-test missiles would be used to prove out this system, which had been given the designation XW-5/RG-X1. Authorization for this modification was issued subsequently by the AEC and design release scheduled for June 1954.

A new high-speed missile, the REGULUS II, was being developed. This would travel at twice the speed of the original REGULUS, or about Mach 2.0, and this increased velocity would more than double the ability of the missile to penetrate enemy defenses without being shot down. Test vehicles of the new design would be available by the fall of 1955, and a feasibility study was authorized by the Secretary of Defense December 1953.[38] The REGULUS II program was promoted to full-scale development stage in April 1955.[39]

Tests of the pressure-sensing system for the XW-5/RG-X1 showed that [redacted] This, however, required additional missile flights, and the design release date was postponed to January 1955.

DoD b(1

On August 19, 1954, the Military Liaison Committee proposed that responsibility for REGULUS adaption kits be transferred to the Navy. A meeting was held October 28, 1954, at which it was decided that this transfer would be made July 1, 1955.[40]

A production-model REGULUS, carrying a Mk 5 Warhead, was launched from the cruiser Los Angeles February 15, 1955, with the missile flight being controlled by an accompanying aircraft. Inflight insertion and command arming were accomplished satisfactorily, although the flight came to an abrupt termination when the warhead was accidentally detonated just short of the target. However, missile and warhead performance were satisfactory throughout the 23-minute flight, which covered 173 miles.[41]

Evaluation flights from submarines were largely successful. Impact tests indicated that the contact crystals generated sufficient voltage to detonate the warhead, and that this detonation occurred prior to warhead deformation. Impacts produced by travel through rain or hail, however, would not cause premature detonation. Thus, the system was given general release.

It had been suggested that the design with the barometric fuze be identified as a Mod change upon entry into stockpile. Action on this suggestion, however, was tabled pending assumption of design control by the Navy. Subsequently, it was decided that the Mk 5 Warhead would be replaced by the Mk 27, and all Sandia activity was suspended on the Mk 5/REGULUS Warhead Installation March 1, 1956.[42]

CHAPTER III

MK 5/MATADOR WARHEAD

The MATADOR was a surface-to-surface, turbojet-powered, transonic missile with a range of about 600 nautical miles. The missile was constructed in the shape of a streamlined fighter plane with an over-all length of 39 feet, maximum diameter of slightly over 4 feet, and swept-back wings. It was launched from a zero-length launcher by a single, solid-propellant rocket, which accelerated the missile until the turbojet engine could attain enough thrust to sustain flight. This rocket booster was pneumatically ejected at time of burnout.

At launch, the missile climbed to an altitude of 40,000 feet, then followed a level trajectory to a "dump point" where it pushed over and dove into the target. Two guidance systems were proposed for use, Shanicle and Marc. Shanicle used four ground stations, which generated guidance beams. The missile received these signals and converted them into azimuth and range guidance. Marc used two trailers that tracked the missile and sent command signals. When the "dive point" was reached with either system, the missile followed a programmed terminal trajectory to the target. MATADOR was designed and built by the Glenn L. Martin Company for the Air Force.

The missile was initially considered for marriage with an XW-5 atomic warhead in early 1950.[43] The MATADOR project was accelerated in late 1950, due to the situation in Korea, and on December 18, 1950, the Joint Chiefs of Staff recommended to the Secretary of Defense that a number of missile projects be approved, among them the MATADOR.[44]

Much of 1951 was taken up with consideration of the solution of general problems relating to the development of atomic warheads for guided missiles, and it was not until October 3, 1951, that an XW-5/MATADOR Ad Hoc Working Group was named by the Guided Missiles Committee and held its first meeting. The Group proposed that both radiating and nonradiating fuzes be considered,

but that--due to program urgency--the TX-5 bomb radar fuze be initially used. Several methods for warhead arming were proposed. One approach would use a clock timer in conjunction with the missile's gyro compass, and another design would incorporate command arming, using the missile's command guidance system. The first of these was felt to be the more reliable.

These recommendations were considered in the December 11, 1951, meeting of the Sandia Weapons Development Board. The Air Force would be responsible for determination of the data upon which the decision to arm or not to arm would be based, and for supplying a suitable signal to the warhead; and Sandia would be responsible for applying this signal to cause arming.[45]

The Division of Military Application wrote to the Military Liaison Committee February 4, 1952. Design release of the Mk 5/MATADOR warhead installation could not be made before February 1953, to allow sufficient time for six sytems flight tests, and production would require another year. The Department of Defense, however, had authorized substantial production of the missile for early 1952, and it thus appeared as though the nuclear warheads would lag the missile by about a year.[46] A request was made that the Mk 5/MATADOR program be expedited, but there appeared to be no way in which this schedule could be shortened.

Detailed consideration of the design in early 1952 resulted in a system that would use a timer which furnished an arming signal after the missile had crossed over into enemy territory. The guidance system would put the missile into a terminal dive if it deviated from its course. If the arming timer did not operate, no nuclear detonation would take place.

A trailing probe was tested to signal burst height by barometric means. However, this device had a number of disadvantages, including problems of storage and release after missile launch, time lag of operation, the fact that only one probe could be installed in the space available, and assembly

had been reduced in weight, and a linear nuclear insertion mechanism installed. This mechanism could be operated either by command signal or arming timer.

A heading-error device built into the missile would cause it to enter a terminal dive, should the missile flight path stray more than certain specified limits from a preset course. An acceleration switch would operate 1 second after missile launch and close a safety switch. After the arming signal was received, a "dump" signal from the missile guidance system would start the fuzing sequence and initiate the terminal dive to the target. When the missile reached a point in the dive where external pressure was equal to one-half sea-level atmosphere, the X-arm baro would close, starting two inverters and charging the firing set. At a preset lower altitude, the fuzing baro would close, placing the two radars in operating condition. These two radars would initially be connected in series, and both would have to "range" (or operate) to detonate the bomb. Slightly below the desired burst altitude, these radars would be reconnected in parallel, so that operation of either radar would detonate the bomb. The impact fuze was not yet available, but was under development, and it was hoped to incorporate it in the Mod 0.

Meanwhile, missile production difficulties were being encountered. Early missile flight tests were also unsuccessful, with the arm signal failing to operate on the first flight; the missile breaking up in the terminal dive in the second; and the missile being destroyed in the third, when it became impossible to correct a severe deviation from the planned flight path. The design-release date was postponed to June 1953.

Three flights were made during March 1953, but all were unsatisfactory from the warhead standpoint, primarily due to missile failure. The AEC stated that it appeared undesirable to continue to divert Mk 5 high-explosive components from current production for use in MATADOR flights until the missile problems were solved and, as a result, further missile flights were postponed.[51]

After missile modifications were made, successful flights were made in August 1953, and warhead installation flights were resumed September 1953.[52] A MATADOR missile with a Mk 5 Warhead was launched from the Air Force Missile Test Center in Florida November 2, 1953. It accepted no commands after takeoff, and was eventually destroyed by removing all carrier guidance and allowing the missile to dive out of control. Reports of a crash in the Bahamas led to recovery of parts of the missile, but the warhead components were never located.[53]

In spite of the lack of flight-test verification, an interim release of the Mk 5/MATADOR warhead installation was made January 1954, and Report SC2982(TR), Interim Design Status Report of the XW-5/B-61A MATADOR, was approved by the Special Weapons Development Board. Additional missile difficulties then developed, and it appeared as though the final release could not be made for several months.[54]

On February 24, 1954, the Air Force Special Weapons Center requested Sandia to provide a barometric fuze for the Mk 5/MATADOR.[55] However, by this time the Military had assumed responsibility for design of new fuzing systems, and this problem was referred to the Air Force, with Sandia services as subcontractor being offered.[56]

Operation BLACK SWAN was established in the spring of 1954. This was a MATADOR Interim Capability Program under which bomb-to-warhead conversion components were supplied on an expedited basis, and associated with five Mk 5 Bombs for use in the event of national emergency.[57] These items were retained for possible use until late 1954.

Report SC3344(TR), Description and Status Report at Design Release of the XW-5/B-61A Atomic Warhead Installation, was presented to the June 30, 1954, meeting of the Special Weapons Development Board.[58] This report was accepted, after some revisions were made to the premature figures, and transmitted to the Division of Military Application. The Final Evaluation of the Mk 5/TM-61A

Atomic Warhead Installation, SC3560(TR), was also reviewed by the Board, July 13, 1955.

DoE b(3)

The warhead, although not being truly a universal design, incorporated many components from other weapons.[59]

Some small effort was made to incorporate an XW-5-X1 Warhead containing the barometric fuze being developed by the Air Force. However, these plans were eventually dropped, and all effort ceased on the Mk 5/MATADOR project in early 1956.[60]

A meeting of Sandia and Bell Aircraft personnel was held September 19, 1950, and initial plans for a missile-warhead formulated. The first glide missile drop was scheduled for April 1951, development launches for early 1952, and interim designs of the terminal guidance system for 1953. The test program would extend to mid-1954. It was suggested that a Mk 5 Bomb with nuclear insertion mechanism and existing fuze be repackaged to suit this missile-warhead combination.

An XW-5/RASCAL Ad Hoc Working Group was appointed and initially met November 7, 1951. The objectives of this Group were to consider problems of arming and fuzing, recommend assignment of tasks, and review proposed solutions.[62] At this time the problems of fuzing atomic warheads for guided missiles had been assigned jointly to the Military and the Atomic Energy Commission by the Department of Defense.

DoE b(3) DoD b(3)

of this objective was not to delay the operational date of the warhead installation. Nonradiating fuzes were desirable, although radiating fuzes would be acceptable if their resistance to jamming was equal to that of an improved Abee or Albert. The missile system would provide an arming signal. A universal fuze, applicable to several missiles, was desirable. Nuclear arming was to be possible at any time during the missile flight, and external means of safing the firing system should be designed.

A study was made of possible means for retaining the nuclear capsule in the event the missile had to be jettisoned. Among the solutions proposed was a spherical clamshell and a removable door on the missile. However, there were many complexities and, as time passed, the problem of scarcity of nuclear material began to ease, and the requirement for capsule retention was dropped.

By early 1952 the design release of the warhead installation was scheduled for July 1954, early production a year later, and stockpiling by October 1955.[63] Shortly thereafter, it was felt that the program could be accelerated by about a year, due to the similarity of the design to the one already considered for the MATADOR missile.[64] The chief carriers of the missile-warhead would be the B-36 and B-47 Air Force bombers. The weapon would be carried in the rear bomb bay of the B-36, and on a pylon under the wing of the B-47.

It was proposed that Sandia design and provide the initial fuze, with a low-altitude fuze study being conducted by both Sandia and Bell Aircraft. Details of the Sandia fuzing system were discussed in the September 24, 1952, meeting of the Ad Hoc Working Group. Sandia advocated the use of a radar system, noting that jamming of these radars would be difficult and expensive. The Military desired a nonemanating fuze, and felt that the system should be of this type. Sandia agreed to develop both systems, with emphasis on a baro-fuze approach.[65]

The Military then proposed that the entire arming and fuzing task be assigned to the Air Force, since they felt that this system and the missile were closely interrelated.[66] This proposal was approved by a majority of the Group and referred, through the Guided Missiles Committee, to the Special Weapons Development Board.[67] The Board agreed that it would be desirable to develop a barometric fuze, since the shallow glide angle of the RASCAL compounded radar problems, but the majority of the Board felt that Sandia should develop the fuze.

The problem was then referred to the Division of Military Application, as noted in Chapter I, and final decision made to assign fuzing responsibility to the Air Force. The problem was turned over to the Bell Aircraft Company, which somewhat reluctantly issued subcontracts to various barometric-switch manufacturers for the development of suitable devices.

replied that the Air Force still desired a RASCAL capability with the XW-5 Warhead, and that Mk 5 flight tests were now scheduled for the period January through September 1956, while missiles configured to carry the XW-27 would not be available until October 1956.[72]

However, further study and negotiation resulted in cancellation of the Mk 5/RASCAL program in March 1956. A quantity of components and hardware to convert Mk 5 Bombs to XW-5-X1/RASCAL warhead installations was retained for a temporary period for possible combat use.[73]

CHAPTER V

MISCELLANEOUS MISSILES

RIGEL

Field Command notified Sandia August 28, 1950, that the Navy was planning to incorporate a Mk 5 Warhead into the RIGEL guided missile.[74] Information regarding this missile was requested from its contractor, the Grumman Aircraft Engineering Corporation, during a missile conference held at Sandia Base September 27-28, 1950. The Navy requested that provisions be made for the RIGEL to carry either the Mk 5, Mk 7 or Mk 8 Warhead.

Field Command pointed out to Sandia, in a letter dated November 29, 1950, that design of the RIGEL contemplated boosted launch from a short-rail launcher. The booster rockets would accelerate the missile from rest to approximately Mach 1.7 in about 4 seconds, after which the boosters would be jettisoned and the ramjet engines would further accelerate the missile to a cruising speed of Mach 2. During the boost phase, the longitudinal acceleration would be as high as 17 g's, and it appeared possible that accelerations of 20 g's might be experienced for short periods of time.[75]

The Mk 5 Warhead could withstand accelerations of 8 to 10 g's, but reduction of RIGEL launch accelerations to this level would require a major program, involving several years of research into composition and burning rates of propellants. Since the prototype warhead for the RIGEL would not be needed until 1954, it was hoped that a rugged implosion-type warhead might be developed by that time, and a request was made that Sandia make preliminary study of a Mk 5 implosion design that could withstand longitudinal accelerations of 20 g's.

A set of detailed missile characteristics was furnished to Sandia April 25, 1951.[76] This described the RIGEL as a supersonic, submarine-to-surface,

bombardment missile with a maximum diameter of 45 inches, a length of over 45 feet, and able to carry a warhead weight of 3000 pounds.

After launch, the missile would climb to a cruising altitude of 50,000 feet and fly to an "area of influence" of guidance stations, where mid-course guidance would be provided. This system was a modified Loran type, using two submerged submarines as control stations. The missile would interrogate the submarines and fly along a hyperbolic path established by these replies. The replies were timed so that the missile path would pass through a target release point. At this point the missile would automatically push over into either a programmed ballistic or homing path to the target. The first tactical missile firing was planned for November 1952, initial firing from a submarine in November 1954, and Fleet evaluation in December 1955.

Little subsequent work was done, however, and, September 30, 1953, the Division of Military Application notified Santa Fe Operations Office that the RIGEL program had been canceled and that requirements for an atomic warhead installation for this missile had been withdrawn.[77]

HERMES

The Sandia Weapons Development Board was notified March 13, 1951, that the Army was developing proximity fuzes for use with the HERMES missile carrying a conventional warhead. It was noted that the military characteristics for these fuzes were similar to those of atomic weapons, except for the higher reliability required in atomic weapons. Inasmuch as this increase in reliability could be achieved by using multiple fuzing, it was suggested that the Board make formal assignment of this project to the Army.[78]

On May 21, 1951, the Division of Military Application sent a teletype to Sandia, stating that the HERMES missile had been deleted from the marriage program, and that the Sandia program should be adjusted accordingly.[79] The

Military Liaison Committee notified the Division of Military Application on June 4, 1951, that the missile had been formally removed from the list of approved weapons projects, but that it had been added to the list of guided-missile test vehicles.[80]

Meetings were held in late 1951, to discuss the possibilities of reinstating the Mk 5 Warhead into the HERMES, so that a missile warhead-compartment design could be produced that would be compatible with Sandia's handling equipment. By May 27, 1952, schedules were being firmed up. Static tests would start April 1953, and flight tests July 1953. The missile operational date would be late 1954, with full production by early 1956. Operational suitability tests of the Mk 5 Warhead in the HERMES missile were planned for mid-1954.[81] General Electric Company, contractor for the HERMES missile, proposed that Sandia enter the project January 1954, by which date the third missile would be available for use.

Sandia was assigned design responsibility for the nose cone, which would have to be pressurized during flight to prevent electrical breakdown of the components. Some difficulty was anticipated with sealing problems, since the ring on which the nose cone was mounted did not lend itself readily to such designs. Sandia suggested, in a letter to Field Command June 9, 1952, that the nose cone be redesigned by the missile contractor, since it was closely associated with the missile airframe design.[82]

Sandia notified the Sandia Field Office of the AEC, June 11, 1952, that conferences with the missile contractor had determined that systems tests could start no earlier than October 1953. Design release would be accomplished by March 1954.[83]

Sandia wrote to Field Command September 25, 1952, stating that nose cones would be furnished for test flights of all HERMES missiles. These would contain inert warheads and Sandia-designed fuzes. It appeared that either a barometrically armed radar fuze or a pure barometric fuze would be used, but it was stated that design responsibility for the fuze had not been formally assigned.

On October 16, 1952, Field Command stated that, due to budget cuts, the HERMES program would be delayed about 6 months.[84] Thus, no current action would be taken on the formation of an Ad Hoc Working Group.[85]

Fiscal funds were still lacking by August 25, 1953.[86] On September 18, 1953, the Military Liaison Committee notified the Division of Military Application that the Army had terminated the development of the HERMES missile as an operational weapon, and that the requirement for an atomic warhead installation for this missile was accordingly withdrawn.[87]

F-101

On April 9, 1953, the Division of Military Application notified Santa Fe Operations Office that the Joint Chiefs of Staff had established a military requirement for development of a streamlined case to enable a supersonic fighter-type aircraft to externally carry the Mk 5 Bomb. Initial application was to be made to F-101 aircraft, and it was considered desirable that the Air Force proceed with the development of the case and the associated non-nuclear components.[88]

A study was made by Wright Air Development Center, after which the Air Force directed McDonnell Aircraft Corporation to develop an externally carried case, named Store 96. This Store was a symmetrical shape 394 inches long and with a maximum diameter of 44 inches. It had three tail fins, with the lower fin retractable to provide ground clearance for loading the weapon and for takeoffs and landings. Gross weight of the shape, including the Mk 5 Warhead and 849 gallons of fuel, was 9240 pounds. The fuel would be expended by the aircraft en route to the target, and, at release, with all fuel expended, the Store would weigh 3776 pounds. The weapon could be released from the carrying aircraft by low-altitude bombing release, M-1 bombing computing system, or by dive bombing, with optical sighting. An ejector mechanism would assist to separate the bomb from the airplane at release.

By fall 1953, the design had progressed to the point where initial test flights could be undertaken by mid-1954 and operational capability could be achieved by January 1956. Early flight tests would be made in B-47 bombers, with 15 drops being made to check out weapon stability and barometric sensing. A subsequent test series would check the fuzing and firing system, and separation under varying conditions.[89]

An XW-5/F-101 Joint Project Group was formed August 1953 to coordinate activities of the Armed Forces Special Weapons Project, the Air Force Special Weapons Center, and Sandia in the shape 96 project.[90] By the July 20, 1954, meeting of the Group, it had been decided to use a radar-timer-contact fuze, and to discard a baro-timer-contact design that had also been considered.[91]

On April 26, 1955, AEC notified Sandia that thermonuclear warheads should be considered for application to the Shape 96. Sandia would provide an appropriate arming and fuzing system.[92] Some thought was given to the application of a Mk 15 Warhead, but this proposal was deleted.[93] In March 1956 the Air Research and Development Command canceled the applications of both the Mk 5 and Mk 27 programs to the F-101, as flight tests had demonstrated fairing problems causing buffeting.[94] Attempts were made to solve these problems; but the program had been delayed to the point that other, and better, weapon combinations became available.[95]

Glossary of Mk 5 Warhead Terms

Air Force Special Weapons Center -- That element of the Air Force Systems Command having to do with compatibility testing of nuclear devices with aircraft. Located at Kirtland Air Force Base, Albuquerque, New Mexico.

Armed Forces Special Weapons Project -- An interdepartment agency formed to handle military functions related to atomic weapons.

Barometric Fuze -- Fuze incorporating a baroswitch. A pressure device actuated by increasing air pressure as the warhead descends in its trajectory.

Capsule -- The nuclear ~~capsule~~ element of an atomic weapon which, when subjected to compression in the implosion process, becomes supercritical and produces a nuclear reaction.

Cartridge -- An assembly, generally containing fuzing and firing system elements, which can be inserted and removed from an atomic weapon in the manner of a cartridge being inserted or removed from the chamber of a rifle.

Contact Fuze -- A fuze that detonates the weapon by contact with the ground or the target.

Department of Defense -- The Armed Forces, i.e., the Army, Navy and Air Force.

Detonators -- Explosive devices which when initiated by the proper signal the same charges of the high explosive sphere. ~~Devices containing bridge wires which, when subjected to an electrical load, burn rapidly and act as a match to apply a flame to various points on the outer surface of the high explosive sphere.~~

Division of Military Application -- An AEC office that functions as liaison between the Military and weapon designers and producers.

Dump -- The point in its trajectory at which a guided missile "dumps" or turns toward the target.

Fat Man Bomb -- The implosion device used during World War II in the attack on Nagasaki. So-called due to its bulging contour.

Field Command -- The local office of the Armed Forces Special Weapons Project, located on Sandia Base, Albuquerque, New Mexico.

Fuze -- A combination of the arming and firing devices of a weapon.

g -- Force equal to one unit gravity.

provided with appropriate lenses charges to implode the explosion

Implosion -- The effect created when a sphere of high explosive is detonated on its exterior surface. The force of the exploding wave is directed largely toward the center of the sphere.

Jato -- Named for Jet-Assisted Take-Off. A jet device initially designed to assist heavily loaded aircraft to take off from short runways. Used as a boosting device in missile launching.

A group composed of the Chiefs of Staff of the

Joint Chiefs of Staff -- ~~An~~ Army-Navy-Air Force ~~group~~ to determine policy and to develop joint strategic objectives of the Armed Forces.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Los Alamos Scientific Laboratory -- A nuclear design organization located at Los Alamos, New Mexico.

Mach -- A measure of speed. Mach 1.0 is the speed of sound, or 738 miles per hour at sea level.

Mark 27 -- A relatively small and light thermonuclear weapon, developed both as bomb and warhead.

Military Liaison Committee -- A Department of Defense Committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

Nautical Mile -- A naval measurement of length. One nautical mile is equivalent to 6076.1033 feet, or the length of 1 minute of arc (1/21,600) of a great circle of the earth.

Prototype -- An early weapon type, generally hand-produced before a production run.

Proximity Fuze -- A fuze that detonates the weapon as soon as it comes within a certain specified distance of the ground or target.

hollow metal shell which receives

Pit -- The ~~space~~ at the center of an implosion bomb. The nuclear capsule is inserted into this space.

Radar -- Named for Radio Detecting and Ranging. Radars emit a pulse of high-frequency energy and measure the time lapse from that transmission to receipt of a reflected electrical "echo" from an object. This time measurement determines the distance of the object from the transmitting antenna of the radar.

Sandia Weapons Development Board -- A joint Sandia-Military board at Sandia Base to provide local guidance on weapons design.

Santa Fe Operations Office -- The local office of the Atomic Energy Commission (AEC) concerned with the operations of Sandia Corporation.

Special Weapons Development Board -- Change of name for the Sandia Weapons Development Board, effective May 14, 1952.

Subsonic -- Any speed below that of Mach 1.0, which is the speed of sound, or 738 miles per hour at sea level.

Supersonic -- Any speed exceeding that of Mach 1.0.

Telemetry -- The transmission of signals from a moving object.

Thermonuclear -- Two-stage reaction, with a fission device exploding and starting a fusion reaction in light elements.

X-Unit -- ~~A high-voltage transformer.~~ A device used to provide high voltage to the weapon detonators.

XW-8 -- A gun-type weapon, designed for target penetration.

Z Division -- A division of the Los Alamos Scientific Laboratory, elements of which moved to Sandia Base and became the nucleus of Sandia Laboratory.

TIMETABLE OF MK 5 WARHEAD EVENTS

1900	Rocketry has beginnings as a science.
1929	Nazis start intensive study of guided missiles.
Early 1946	Rand Project founded. Early rocket-study work.
3-46	Army Air Forces institute work on Project MASTIFF, an experimental missile.
1-10-47	Early proposals for atomic warheads.
4-29-49	Division of Military Application requests views of Military Liaison Committee on missile/atomic warhead work.
1-27-50	Detailed studies of missile/atomic warheads approved.
6-21-50	Sandia Weapons Development Board accepts cognizance of missile/warhead work.
10-1-50	Department 1270 established at Sandia for missile/warhead design.
9-11-51	Military characteristics for XW-5 Warhead issued.
8-53	Mk 5 Mod 0 Warhead design released.
7-54	Mk 5 Mod 0 Warhead enters production.

Mk 5/REGULUS

1-50	Project approved by Secretary of Defense.
1-51	Missile/warhead placed in active design.
9-10-51	XW-5/REGULUS Ad Hoc Working Group meets.
8-18-52	RAM Project initiated.
10-28-52	Flight tests of XW-5/REGULUS started.
9-53	Design release of Mk 5/REGULUS.
4-54	Initial production of Mk 5/REGULUS.

The success of the Germans in developing the V-missiles and the later appearance of the atomic bomb led observers to believe that a quick "marriage" of the two would follow and inaugurate an era of "pushbutton warfare." Such estimates failed to evaluate properly the complexities attendant on the development of each device and the relatively primitive state of each.[2] Lacking were such factors as reliable guidance systems, competent propulsion systems, shock-resistant warheads, and the high-quality, or "clean-room," type of manufacturing facilities yet to be developed. However, early military characteristics for an air-to-ground missile had been proposed by the Army Air Force October 19, 1945, envisioning a warhead 60 inches in diameter, 130 inches long, and 11,000 pounds in weight (in obvious reference to the Fat Man bomb), although missiles capable of carrying a warhead of this size and weight would not be available for several years.

In March 1946 the Army Air Force directed the Air Materiel Command to develop an experimental missile, and this project was given a code name of MASTIFF.[3] At the time, little information regarding MASTIFF was made available to those working on the atomic bomb, but in one of his last actions, December 12, 1946, as head of the Manhattan Engineer District and prior to AEC assumption of control, Brig. Gen. Leslie R. Groves informed the Los Alamos Scientific Laboratory concerning the project, and stated that it envisaged installation of an atomic warhead in an air-to-ground guided missile.

This information was referred to the Z Division on January 10, 1947, with a request that preliminary analysis be made, but that any sizable amount of development work be deferred until later in the year when the work load was expected to taper off.[4] Subsequently, little was done on the project in either AEC or military circles beyond a general study that contemplated use of a plane-launched drone which would glide 300 miles to a target at a speed of 300 miles per hour. However, a drone with this speed was felt to be highly vulnerable to antiaircraft fire, and the existing scarcity of nuclear material, together with the inaccuracy of drone control systems, caused apprehension that an atomic weapon might be used to bomb some unoccupied field. In mid-1947, missile development for the MASTIFF project

Subsequently, separate conferences were held with the three Services and Sandia Base representatives of the Armed Forces Special Weapons Project. These conferences explored the details of weapon-missile relationships, placing emphasis on Mk 5 and Mk 8 Warheads.

The Sandia Weapons Development Board provided a common forum for designer and user of atomic weapons and, in a meeting June 21, 1950, agreed to accept responsibility for coordinating guided-missile and atomic-warhead development. The Board proposed that a strong missile subcommittee be formed, but temporarily deferred appointments to this subcommittee, pending arrival of new officer assignments at Sandia and Kirtland Air Force Bases.[8]

The Division of Military Application had noted, in a letter dated June 14, 1950, that some controversy had arisen over the subject of responsibility for warhead fuzing. Army Ordnance had assumed that the Atomic Energy Commission would handle fuze development, but the AEC felt that the fuze characteristics would be strongly affected by missile operation and environment, and therefore the fuze should be designed by the missile agency.[9]

This subject was discussed in the June 21, 1950, meeting of the Sandia Weapons Development Board. One proposal was that the AEC provide funds for fuze development and retain nominal control of the project, with the work being accomplished by Army Ordnance or missile contractor. The Board in general felt that the missile was simply a carrier, that it replaced the aircraft carrying bombs, and that the fuze was part of warhead development. However, it was recognized that there was no easily defined line of demarcation between warhead and missile (such as between bomb and bomber), and the eventual ruling was that a decision on fuzing design responsibility would be made for each individual missile-warhead project. The Board proposed that AEC budget for fuzing development costs in the immediate future and that these funds be allocated to the military or AEC contractor assigned responsibility for fuze development.

involved, that of ballistic (where the missile was launched upward and then fell into a target) and that of release from a carrier downward onto a target.

The Division of Military Application notified the Military Liaison Committee, January 19, 1951, that increasing requirements for various combinations of missiles and warheads had reached the point where standardization of warhead design was becoming difficult, if not impossible, to achieve. It was felt that the design of the Mk 5 and Mk 7 Warheads had progressed to the point where these warheads could be proposed for marriage with missiles and eliminate any need for alternate warheads.[16]

A nomenclature system having the prefix "XW" to identify warheads under design, similar to the "TX" identification for bombs, was authorized in mid-January 1951. This prefix was followed by the warhead identification (Mark number) and was coupled with the missile designator for complete missile-warhead nomenclature. The "X" stood for experimental, and the "W" for warhead. A typical example was: XW-5/REGULUS.[17]

Detailed design was meanwhile proceeding on the arming system. It was felt that automatic arming should be provided, which would take place only after the missile had crossed into enemy territory, and it had been proposed that the missile guidance system be used to signal this fact. However, there was such a complexity of missiles, with different guidance systems, that this was found to be impracticable. It was possible, however, to provide a system that would sense the initial missile speed, the existence of high-enough thrust for long-enough time, the attainment of sufficient altitude, and the pursuance of the correct direction. All these factors could be gaged by gyroscopes, clocks and acceleration switches, and a system could be devised to permit nuclear insertion only when all these factors had been met or exceeded. Sandia provided such a system for all missile-warhead combinations, with the gyroscope, clock, or switch shorted out when a given missile had no need to measure that particular factor.[18]

Sandia presented a status report on its warhead-missile program February 23, 1951, when it was visited by Kaufman T. Keller, Chairman of the Board of the Chrysler Corporation, who had been appointed Director of the Guided Missiles Office by the Secretary of Defense. Keller noted that he had visited a good many places in his work as Missile Czar, but that he was "not going to worry about a place as obviously competent as this one." High praise indeed for Sandia work in this new field.[19]

Work began in earnest on warhead designs after AEC budgetary decisions were made May 31, 1951. It had become evident that much redesign would be required to strengthen the Mk 4 before it could be used as a warhead, and it was also evident that missiles capable of carrying such a heavy warhead were still some years in the future. Thus it was decided to suspend consideration of either the Mk 4 or Mk 6 weapon for current missile applications.

The question of fuzing responsibility was again raised. The first Ad Hoc Working Group to take action in this area, that for the XW-7/CORPORAL, recommended that Sandia provide an interim fuzing system, with Army Ordnance being responsible for the ultimate fuzing design. This proposal was approved by the Sandia Weapons Development Board June 27, 1951, and similar suggestions for the XW-5/REGULUS and XW-5/MATADOR were made and accepted in September and December 1951. These decisions were based on the fact that Sandia fuzes developed for bomb programs were the only systems capable of meeting time scales and adequately accomplishing the technical job.

Allocation of ultimate fuze design to the Army resulted in a request from that agency for AEC funds to develop an ultimate fuze for the XW-7/CORPORAL.[20] This request was referred to the Board, which decided in January 1952 to reduce the scope of the CORPORAL ultimate fuzing study to that of feasibility investigation.[21]

TRITON missiles. The warhead was not to exceed 44 inches in diameter, 77-1/2 inches in length, and 3000 pounds in weight. (b)(1), (b)(3)

Nonradiating fuzes were felt to be highly desirable, setting of burst height was to be possible just prior to missile launching, and preflight checks were to be of a simple accept or reject type.

The warhead was to be capable of withstanding accelerations of +7 g's and -5.5 g's along the longitudinal axis of the missile, although the RIGEL might require resistance against +20 g's. Accelerations of ±3.5 g's along the lateral axis and ±4 g's along any other axis would also have to be withstood. The warhead was to be able to resist temperatures from -65 to +160°F, and altitudes up to 80,000 feet. Air-launched missile warheads would have to withstand flights in the parent aircraft of up to 15 hours at 40,000 feet; and submarine-launched missiles would have to provide for storage of the warhead in the missile for as long as 75 days.[24]

A variety of interpretations had previously been given to definition of warhead and warhead installation, and were standardized by the Sandia Weapons Development Board December 11, 1951. The warhead was defined as the nuclear pit and capsule, high-explosive sphere, detonators, X-unit, firing switch, nuclear insertion mechanism, and all hardware and cabling pertaining to these items. The warhead installation included the warhead, arming and fuzing system, power supply, and installation hardware. The warhead installation thus might vary for different missiles, even though the same warhead was used.[25]

The XW-5 Warhead would contain a Mk 5 Bomb implosion system, a Mk 5 Firing Set with a fast-firing X-unit and switch for contact bursts, and a new linear nuclear insertion mechanism.[26] Mk 5 nuclear capsules would be

used. This would produce a warhead 44 inches in diameter and 75-1/2 inches in length with a weight of 2550 pounds, excluding power supply, arming and fuzing, and mounting hardware.[27]

The Sandia Weapons Development Board ruled that the warhead installation should not be design released until six successful tests of the warhead in the missile had been made. Missile availability dates were still largely indefinite, but it was felt that at least 9 months would be required between design release and early production.

The Mk 5 Mod 0 Warhead was design released August 1953, and production was achieved July 1954. The warhead incorporated a linear nuclear insertion mechanism, but otherwise was identical with the Mk 5 Bomb less outer case. (b)(1), (b)(3)

A Mk 5 Mod 1 Warhead was proposed for use with the RASCAL missile, incorporating dual-motor nuclear insertion mechanism, but was canceled during design, April 16, 1956.[28]

Investigation was undertaken of both forward extending pressure probes and trailing devices. It was hoped to develop a simple barometric fuze, but tests showed that the pressure pickups did not give reproducible results, and that the missile would have to travel faster than Mach 1.0 to prevent premature fuze operation.[32] A decision was made to use a baro-armed radar fuze, a modification of the fuze design of the Mk 5 Bomb.[33]

In early 1952 the Mk 5/REGULUS was given a higher priority than its Mk 8 counterpart, since there was a limitation in the number of missiles available for test flights.[34] Work was started on a contact fuze for several missiles, and successful completion of this task made it possible to provide the XW-5/REGULUS with two fuzing options; radar air burst with contact-fuze backup, and surface burst by impact crystals.

The Navy had requested that a pure barometric fuze be developed, and this was discussed in the June 27, 1952, meeting of the Ad Hoc Working Group. Sandia reported that this design would require an additional 10 months, and that it was not at all certain that such fuze would have the required accuracy. The Group, after considerable discussion, decided to approve the radar fuze for use in the REGULUS and to continue development of a barometric fuze.

The RAM Program (for REGULUS Assault Missile) was initiated by a letter from the Military Liaison Committee to the Division of Military Application August 18, 1952. This was a project to provide the capability for launching the REGULUS missile from a surface ship, guiding the missile to target, and arming and detonating the warhead by command from carrier-based fighter aircraft.[35]

The program was given a high priority in mid-February 1953, and a small number of Mk 5 Bombs were placed in standby storage April 1953, together with the hardware to convert these bombs to RAM installation, which had been renamed the REGULUS Interim Capability Program. These units were subsequently retired in mid-1954, as normal XW-5/REGULUS components became available.[36]

A new high-speed missile, the REGULUS II, was being developed. This would travel at twice the speed of the original REGULUS, or about Mach 2.0, and this increased velocity would more than double the ability of the missile to penetrate enemy defenses without being shot down. Test vehicles of the new design would be available by the fall of 1955, and a feasibility study was authorized by the Secretary of Defense December 1953.[38] The REGULUS II program was promoted to full-scale development stage in April 1955.[39]

Tests of the pressure-sensing system for the XW-5/RG-X1 showed that excessive lag was involved. This was traced to collapse of rubber tubing in the system, and was corrected by the use of metal tubing. This, however, required additional missile flights, and the design release date was postponed to January 1955.

On August 19, 1954, the Military Liaison Committee proposed that responsibility for REGULUS adaption kits be transferred to the Navy. A meeting was held October 28, 1954, at which it was decided that this transfer would be made July 1, 1955.[40]

(b)(3)

Inflight insertion and command arming were accomplished satisfactorily, although the flight came to an abrupt termination when the warhead was accidentally detonated just short of the target. However, missile and warhead performance were satisfactory throughout the 23-minute flight, which covered 173 miles.[41]

Evaluation flights from submarines were largely successful. Impact tests indicated that the contact crystals generated sufficient voltage to detonate the warhead, and that this detonation occurred prior to warhead deformation. Impacts produced by travel through rain or hail, however, would not cause premature detonation. Thus, the system was given general release.

It had been suggested that the design with the barometric fuze be identified as a Mod change upon entry into stockpile. Action on this suggestion, however, was tabled pending assumption of design control by the Navy. Subsequently, it was decided that the Mk 5 Warhead would be replaced by the Mk 27, and all Sandia activity was suspended on the Mk 5/REGULUS Warhead Installation March 1, 1956.[42]

CHAPTER III

MK 5/MATADOR WARHEAD

The MATADOR was a surface-to-surface, turbojet-powered, transonic missile with a range of about 600 nautical miles. The missile was constructed in the shape of a streamlined fighter plane with an over-all length of 39 feet, maximum diameter of slightly over 4 feet, and swept-back wings. It was launched from a zero-length launcher by a single, solid-propellant rocket, which accelerated the missile until the turbojet engine could attain enough thrust to sustain flight. This rocket booster was pneumatically ejected at time of burnout.

At launch, the missile climbed to an altitude of 40,000 feet, then followed a level trajectory to a "dump point" where it pushed over and dove into the target. Two guidance systems were proposed for use, Shanicle and Marc. Shanicle used four ground stations, which generated guidance beams. The missile received these signals and converted them into azimuth and range guidance. Marc used two trailers that tracked the missile and sent command signals. When the "dive point" was reached with either system, the missile followed a programmed terminal trajectory to the target. MATADOR was designed and built by the Glenn L. Martin Company for the Air Force.

The missile was initially considered for marriage with an XW-5 atomic warhead in early 1950.[43] The MATADOR project was accelerated in late 1950, due to the situation in Korea, and on December 18, 1950, the Joint Chiefs of Staff recommended to the Secretary of Defense that a number of missile projects be approved, among them the MATADOR.[44]

Much of 1951 was taken up with consideration of the solution of general problems relating to the development of atomic warheads for guided missiles, and it was not until October 3, 1951, that an XW-5/MATADOR Ad Hoc Working Group was named by the Guided Missiles Committee and held its first meeting. The Group proposed that both radiating and nonradiating fuzes be considered,

SECRET
RESTRICTED DATA

CHAPTER IV

MK 5/RASCAL WARHEAD

The RASCAL was an air-to-surface, rocket-powered, supersonic missile with a 90-nautical-mile range. The missile was 32 feet long and 4 feet in diameter, with one set of four fins near the nose and another at the tail. The missile was developed by the Bell Aircraft Company for the Air Force. Its name was formed from the title RAdar SCAnning Link.[61]

After launch from the carrying bomber at an altitude between 30,000 and 40,000 feet, the RASCAL was to climb to an altitude of 60,000 feet, and cruise at Mach 2.5. The missile was given mid-course guidance by the launch aircraft. Terminal guidance during the dive to the target was provided by an inertial system and terminal guidance radar which searched the target area and relayed a video output to the launch aircraft. In this airplane, one operator tracked the target in range while another operator tracked it in azimuth. This information was fed into a computer which relayed guidance commands to the missile.

The program was initially proposed in a letter from the Military Liaison Committee March 16, 1950, which listed several missiles which were to be considered for marriage with nuclear warheads. The August 20, 1950, meeting of the Sandia Weapons Development Board noted that it should be fairly easy to develop a nuclear insertion device for the missile, and that the RASCAL had several features that made it particularly appropriate for use. The missile terminal guidance system contained information concerning height of the missile above target, and could be used as the warhead fuze. The missile would be launched only after the mother plane had penetrated enemy territory, so the warhead could be armed before launch.

replied that the Air Force still desired a RASCAL capability with the XW-5 Warhead, and that Mk 5 flight tests were now scheduled for the period January through September 1956, while missiles configured to carry the XW-27 would not be available until October 1956.[72]

However, further study and negotiation resulted in cancellation of the Mk 5/RASCAL program in March 1956. A quantity of components and hardware to convert Mk 5 Bombs to XW-5-X1/RASCAL warhead installations was retained for a temporary period for possible combat use.[73]

CHAPTER V

MISCELLANEOUS MISSILES

RIGEL

Field Command notified Sandia August 28, 1950, that the Navy was planning to incorporate a Mk 5 Warhead into the RIGEL guided missile.[74] Information regarding this missile was requested from its contractor, the Grumman Aircraft Engineering Corporation, during a missile conference held at Sandia Base September 27-28, 1950. The Navy requested that provisions be made for the RIGEL to carry either the Mk 5, Mk 7 or Mk 8 Warhead.

Field Command pointed out to Sandia, in a letter dated November 29, 1950, that design of the RIGEL contemplated boosted launch from a short-rail launcher. The booster rockets would accelerate the missile from rest to approximately Mach 1.7 in about 4 seconds, after which the boosters would be jettisoned and the ramjet engines would further accelerate the missile to a cruising speed of Mach 2. During the boost phase, the longitudinal acceleration would be as high as 17 g's, and it appeared possible that accelerations of 20 g's might be experienced for short periods of time.[75]

The Mk 5 Warhead could withstand accelerations of 8 to 10 g's, but reduction of RIGEL launch accelerations to this level would require a major program, involving several years of research into composition and burning rates of propellants. Since the prototype warhead for the RIGEL would not be needed until 1954, it was hoped that a rugged implosion-type warhead might be developed by that time, and a request was made that Sandia make preliminary study of a Mk 5 implosion design that could withstand longitudinal accelerations of 20 g's.

A set of detailed missile characteristics was furnished to Sandia April 25, 1951.[76] This described the RIGEL as a supersonic, submarine-to-surface,

bombardment missile with a maximum diameter of 45 inches, a length of over 45 feet, and able to carry a warhead weight of 3000 pounds.

After launch, the missile would climb to a cruising altitude of 50,000 feet and fly to an "area of influence" of guidance stations, where mid-course guidance would be provided. This system was a modified Loran type, using two submerged submarines as control stations. The missile would interrogate the submarines and fly along a hyperbolic path established by these replies. The replies were timed so that the missile path would pass through a target release point. At this point the missile would automatically push over into either a programmed ballistic or homing path to the target. The first tactical missile firing was planned for November 1952, initial firing from a submarine in November 1954, and Fleet evaluation in December 1955.

Little subsequent work was done, however, and, September 30, 1953, the Division of Military Application notified Santa Fe Operations Office that the RIGEL program had been canceled and that requirements for an atomic warhead installation for this missile had been withdrawn.[77]

HERMES

The Sandia Weapons Development Board was notified March 13, 1951, that the Army was developing proximity fuzes for use with the HERMES missile carrying a conventional warhead. It was noted that the military characteristics for these fuzes were similar to those of atomic weapons, except for the higher reliability required in atomic weapons. Inasmuch as this increase in reliability could be achieved by using multiple fuzing, it was suggested that the Board make formal assignment of this project to the Army.[78]

On May 21, 1951, the Division of Military Application sent a teletype to Sandia, stating that the HERMES missile had been delcted from the marriage program, and that the Sandia program should be adjusted accordingly.[79] The

Military Liaison Committee notified the Division of Military Application on June 4, 1951, that the missile had been formally removed from the list of approved weapons projects, but that it had been added to the list of guided-missile test vehicles.[80]

Meetings were held in late 1951, to discuss the possibilities of reinstating the Mk 5 Warhead into the HERMES, so that a missile warhead-compartment design could be produced that would be compatible with Sandia's handling equipment. By May 27, 1952, schedules were being firmed up. Static tests would start April 1953, and flight tests July 1953. The missile operational date would be late 1954, with full production by early 1956. Operational suitability tests of the Mk 5 Warhead in the HERMES missile were planned for mid-1954.[81] General Electric Company, contractor for the HERMES missile, proposed that Sandia enter the project January 1954, by which date the third missile would be available for use.

Sandia was assigned design responsibility for the nose cone, which would have to be pressurized during flight to prevent electrical breakdown of the components. Some difficulty was anticipated with sealing problems, since the ring on which the nose cone was mounted did not lend itself readily to such designs. Sandia suggested, in a letter to Field Command June 9, 1952, that the nose cone be redesigned by the missile contractor, since it was closely associated with the missile airframe design.[82]

Sandia notified the Sandia Field Office of the AEC, June 11, 1952, that conferences with the missile contractor had determined that systems tests could start no earlier than October 1953. Design release would be accomplished by March 1954.[83]

Sandia wrote to Field Command September 25, 1952, stating that nose cones would be furnished for test flights of all HERMES missiles. These would contain inert warheads and Sandia-designed fuzes. It appeared that either a barometrically armed radar fuze or a pure barometric fuze would be used, but it was stated that design responsibility for the fuze had not been formally assigned.

On October 16, 1952, Field Command stated that, due to budget cuts, the HERMES program would be delayed about 6 months.[84] Thus, no current action would be taken on the formation of an Ad Hoc Working Group.[85]

Fiscal funds were still lacking by August 25, 1953.[86] On September 18, 1953, the Military Liaison Committee notified the Division of Military Application that the Army had terminated the development of the HERMES missile as an operational weapon, and that the requirement for an atomic warhead installation for this missile was accordingly withdrawn.[87]

F-101

On April 9, 1953, the Division of Military Application notified Santa Fe Operations Office that the Joint Chiefs of Staff had established a military requirement for development of a streamlined case to enable a supersonic fighter-type aircraft to externally carry the Mk 5 Bomb. Initial application was to be made to F-101 aircraft, and it was considered desirable that the Air Force proceed with the development of the case and the associated non-nuclear components.[88]

A study was made by Wright Air Development Center, after which the Air Force directed McDonnell Aircraft Corporation to develop an externally carried case, named Store 96. This Store was a symmetrical shape 394 inches long and with a maximum diameter of 44 inches. It had three tail fins, with the lower fin retractable to provide ground clearance for loading the weapon and for takeoffs and landings. Gross weight of the shape, including the Mk 5 Warhead and 849 gallons of fuel, was 9240 pounds. The fuel would be expended by the aircraft en route to the target, and, at release, with all fuel expended, the Store would weigh 3776 pounds. The weapon could be released from the carrying aircraft by low-altitude bombing release, M-1 bombing computing system, or by dive bombing, with optical sighting. An ejector mechanism would assist to separate the bomb from the airplane at release.

Glossary of Mk 5 Warhead Terms

Air Force Special Weapons Center — That element of the Air Force Systems Command having to do with compatibility testing of nuclear devices with aircraft. Located at Kirtland Air Force Base, Albuquerque, New Mexico.

Armed Forces Special Weapons Project — An interdepartment agency formed to handle military functions related to atomic weapons.

Barometric Fuze — Fuze incorporating a baroswitch. A pressure device actuated by increasing air pressure as the warhead descends in its trajectory.

Capsule — The nuclear ~~capsule~~ of an atomic weapon which, when subjected to compression in the implosion process, becomes supercritical and produces a nuclear reaction.

Cartridge — An assembly, generally containing fuzing and firing system elements, which can be inserted and removed from an atomic weapon in the manner of a cartridge being inserted or removed from the chamber of a rifle.

Contact Fuze — A fuze that detonates the weapon by contact with the ground or the target.

Department of Defense — The Armed Forces, i.e., the Army, Navy and Air Force.

Detonators — ~~Devices containing bridge wires which, when subjected to an electrical load, burn rapidly and act as a match to apply a flame to various points on the outer surface of the high explosive sphere.~~

Division of Military Application — An AEC office that functions as liaison between the Military and weapon designers and producers.

Dump — The point in its trajectory at which a guided missile "dumps" or turns toward the target.

Fat Man Bomb — The implosion device used during World War II in the attack on Nagasaki. So-called due to its bulging contour.

Field Command — The local office of the Armed Forces Special Weapons Project, located on Sandia Base, Albuquerque, New Mexico.

Fuze — A combination of the arming and firing devices of a weapon.

g — Force equal to one unit gravity.

Implosion — The effect created when a sphere of high explosive is detonated on its exterior surface. The force of the exploding wave is directed largely toward the center of the sphere.

Jato — Named for Jet-Assisted Take-Off. A jet device initially designed to assist heavily loaded aircraft to take off from short runways. Used as a boosting device in missile launching.

Joint Chiefs of Staff — An Army-Navy-Air Force group to determine policy and to develop joint strategic objectives of the Armed Forces.

Kiloton — A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Los Alamos Scientific Laboratory — A nuclear design organization located at Los Alamos, New Mexico.

Mach — A measure of speed. Mach 1.0 is the speed of sound, or 738 miles per hour at sea level.

Mark 27 — A relatively small and light thermonuclear weapon, developed both as bomb and warhead.

Military Liaison Committee — A Department of Defense Committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

Nautical Mile — A naval measurement of length. One nautical mile is equivalent to 6076.1033 feet, or the length of 1 minute of arc (1/21,600) of a great circle of the earth.

(b)(3)

Radar — Named for Radio Detecting and Ranging. Radars emit a pulse of high-frequency energy and measure the time lapse from that transmission to receipt of a reflected electrical "echo" from an object. This time measurement determines the distance of the object from the transmitting antenna of the radar.

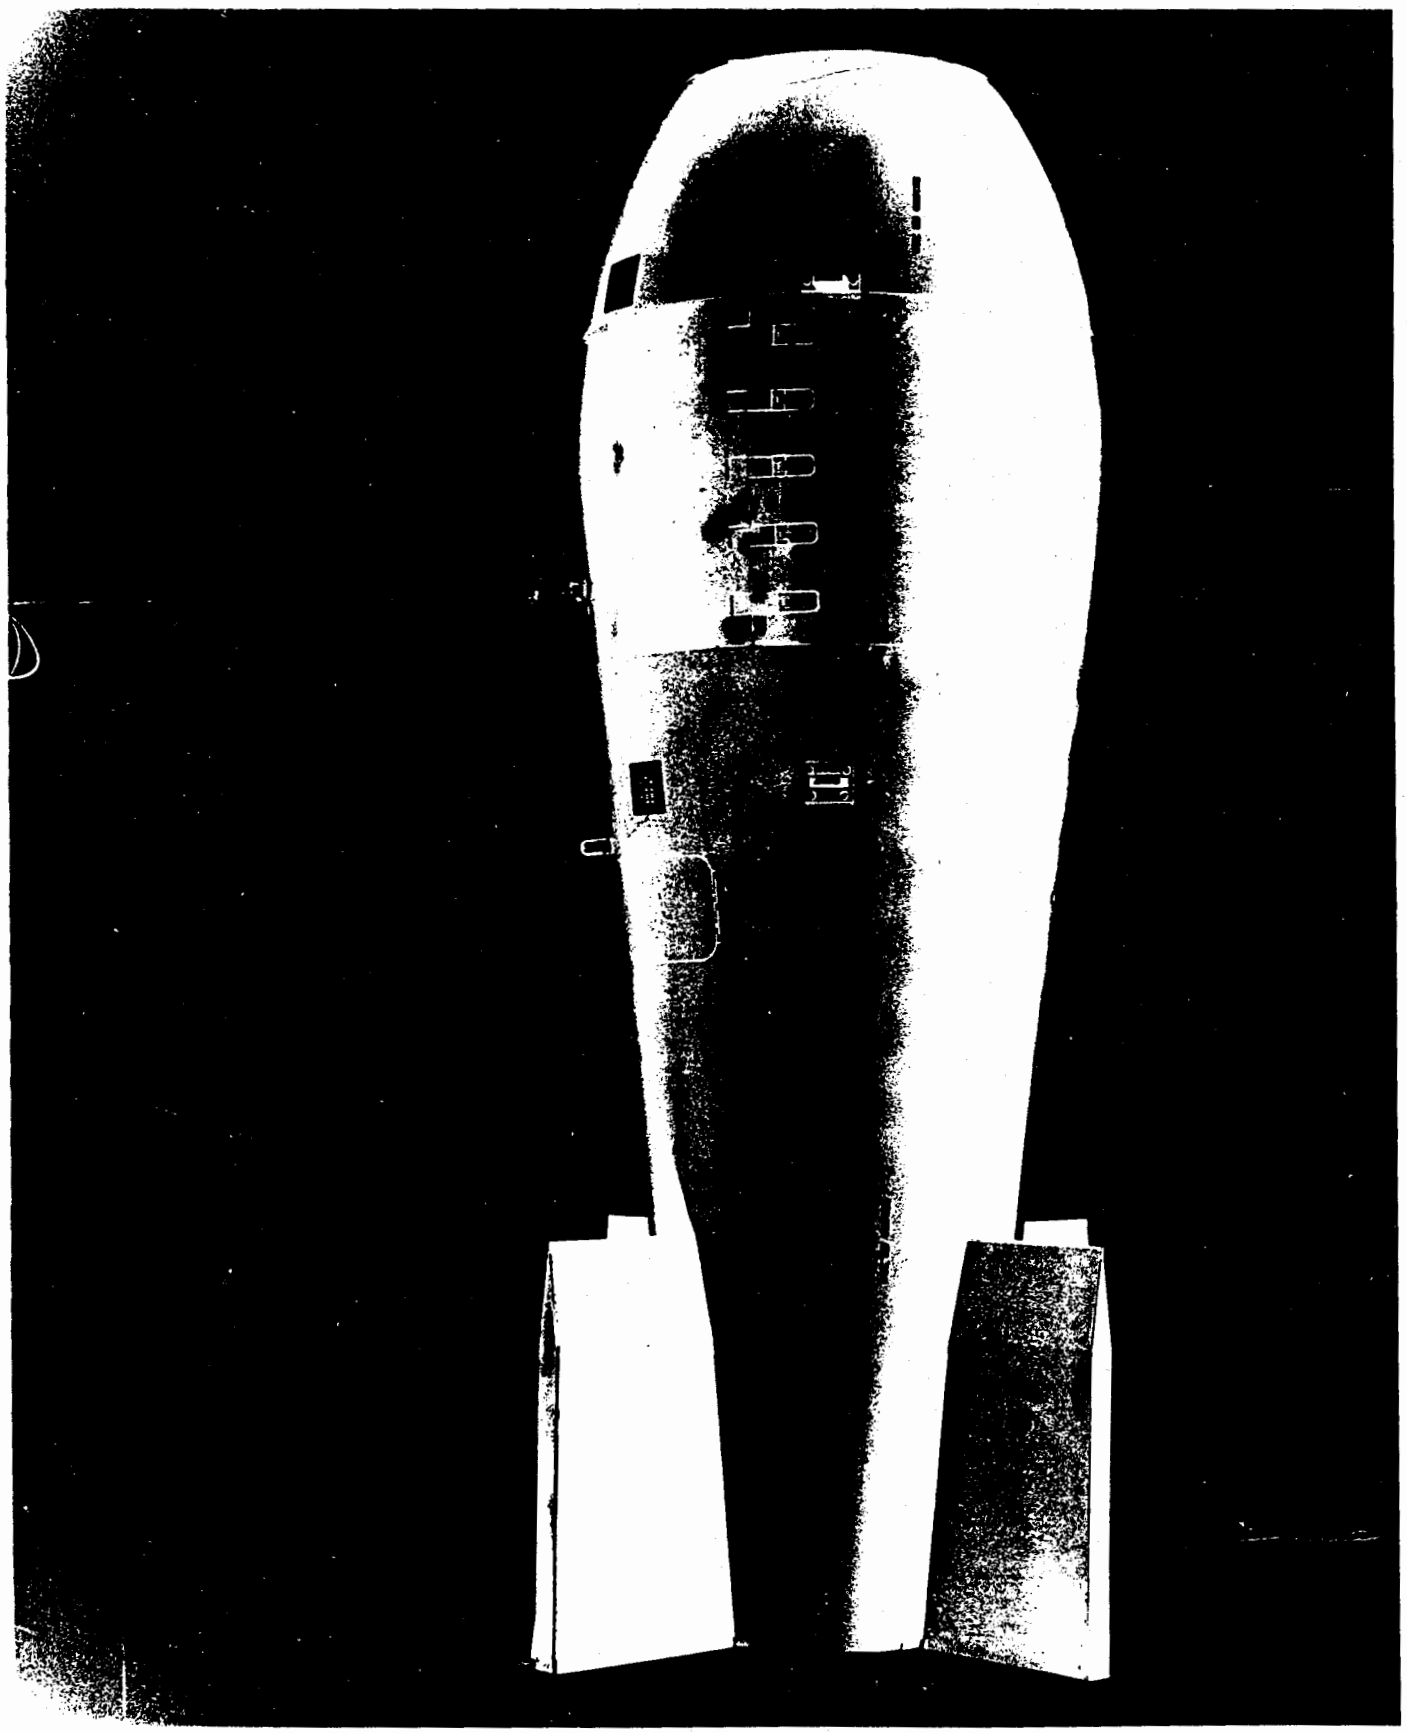
Sandia Weapons Development Board — A joint Sandia-Military board at Sandia Base to provide local guidance on weapons design.

Santa Fe Operations Office — The local office of the Atomic Energy Commission (AEC) concerned with the operations of Sandia Corporation.

Special Weapons Development Board — Change of name for the Sandia Weapons Development Board, effective May 14, 1952.

Subsonic — Any speed below that of Mach 1.0, which is the speed of sound, or 738 miles per hour at sea level.

Supersonic — Any speed exceeding that of Mach 1.0.



Telemetry — The transmission of signals from a moving object.

Thermonuclear — Two-stage reaction, with a fission device exploding and starting a fusion reaction in light elements.

X-Unit — ~~A high voltage transformer~~ A device used to provide high voltage to the weapon detonators.

XW-8 — A gun-type weapon, designed for target penetration.

Z Division — A division of the Los Alamos Scientific Laboratory, elements of which moved to Sandia Base and became the nucleus of Sandia Laboratory.

HISTORY OF THE MK 5 BOMB

The feasibility of creating a small implosion bomb was one of the weapon concepts studied by the Los Alamos Scientific Laboratory after the end of World War II. The over-all size of the wartime Fat Man device (which was to be as large as possible) had been established by the dimensions of the B-29 bomb bay and the existing state of implosion theory, and the resulting weapon was a bomb with reasonably high nuclear efficiency, but which was difficult to handle due to its bulk and weight (60-inch diameter; 128-inch length; 10,900-pound weight). Consequently, calculations were made of compressions produced by small-diameter high-explosive spheres, and different arrangements of nuclear material were studied.

This small implosion design was of interest to the Military, and the Military Liaison Committee informed the Atomic Energy Commission October 31, 1947, that current implosion bombs did not lend themselves to wide or flexible employment, and that a weapon both lighter and smaller than the Mk 4 (then in design) would be of considerable military importance.[1] The Atomic Energy Commission, in replying to this letter on December 10, 1947, pledged support of a vigorous program to develop a small bomb.[2]

Meanwhile the Division of Military Application wrote to Santa Fe Operations Office November 25, 1947, noting that any reduction in bomb weight would result in an increased range of the carrying aircraft and pointed out that: "Reduced dimensions might open up an entire new field of flexibility in the employment which could be a decisive influence in the military capability of getting the bombs home in war."

[redacted]

DoD b(1)

During 1948, it became apparent that determination of size, shape and weight for the lighter and smaller weapon required an understanding of military aircraft, delivery plans and problems. A conference was consequently held at Los Alamos September 2 and 3, 1948, which was attended by representatives of the Military, AEC weapon laboratories, and cleared members of the aircraft industry. It was decided that a bomb with a diameter of 40 to 48 inches and weighing between 5000 and 6000 pounds would cause significant improvement in aircraft performance and increase the probability of successful weapon delivery. It was felt that the length of the weapon should be retained at 128 inches.[4]

DoD b(3)

DoE b(3)

During the foregoing study period, the project had been known as the Small Weapon Program and was directed by the Los Alamos Committee for Weapon Development. It was subsequently transferred, October 11, 1948, to the W (Weapon Development) Division of Los Alamos with the request that this Division undertake an "experimental, calculational, and fabrication program aimed at the production of a specific model of a complete small weapon for test early in 1951."[6]

The Committee for Weapon Development and the Military Liaison Committee had previously determined that the yield should be [redacted] kilotons; nuclear safing was mandatory; fuzing requirements should be based on the results of a height-of-burst study then in process; and the bomb should be an internally carried, free-fall, air-burst weapon.

DoE b(3)

The work of the W Division almost immediately involved the Sandia Branch of the Los Alamos Scientific Laboratory and, it was suggested that a Steering Committee be established to direct development work on the weapon.[7] This new group initially met November 3, 1948, and the Chairman noted that much confusion had previously arisen due to various terms used to identify a given weapon, and suggested that a standard weapon name as well as a designation for the Steering Committee be established.[8] Mk IV nomenclature had already been assigned, so it was logical to use the next number, Mk V, for this device. The Committee felt, however, that development models of the weapon should be specifically identified, and it was decided to use the letter "X" as a prefix to show the experimental nature of the design. It was also decided to add the letter "T" to indicate--in the phraseology of the Committee's minutes--"the word 'tentative' or 'tiny' (or something)." Thus the weapon became known as TX-V (and, soon thereafter, the TX-5) and the Committee as the TX-5 Steering Committee. The adoption of this system set the pattern for many subsequent atomic devices.[9]

[redacted]

DoE b(3)

DoE b(3)

[redacted] The possibilities of contact or even subsurface burst requirements were briefly considered, but it was felt that the basic design of an implosion weapon made anything but air burst impossible.

DOE b(3)

[redacted]

DOE b(3)

[redacted] Computer time was scheduled, and it was hoped to have compression figures in about 3 months.[10] (Subsequently, due to the pressure of other computer programs, it was decided to interpolate, using other computational results.) The Steering Committee established a schedule calling for preliminary design by January 1, 1950, and complete design July 1, 1950.

DOE b(3)

[redacted]

The contents of a December 10, 1948, letter from the AEC General Advisory Committee were discussed in the January 7, 1949, meeting of the TX-5 Steering Committee. This letter stated that reduction of size and weight of atomic weapons was vitally important to national defense and that the AEC wholeheartedly supported the aims of the Steering Committee in this regard. The Advisory Committee hoped that the new small weapon could be ready for production soon after proof-firing, and suggested that a substantial portion of the implosion stockpile in early 1950 be made up of the new bomb. The program was accordingly accelerated.[12]

Problems of nuclear safing had meanwhile been studied. The Sandia Research and Development Board (later renamed Sandia Weapons Development Board and, still later, Special Weapons Development Board) was a group including representatives from Sandia and the Armed Forces Special Weapons Project, the military organization formed to handle military problems connected with the atomic bomb. The Board held an initial meeting March 2, 1948, and suggested that design attention be paid to the possibility of extracting

Consideration was given to the necessity for duplicate bridge wires in each detonator [redacted] DoE b(3)

[redacted] The use of single bridge wires was then proposed, with two X-units connected in parallel to each bridge wire. This raised the question as to whether one X-unit would fire back through the other, rather than across the bridge wires, and it was eventually decided to provide one highly reliable X-unit and to use single bridge wires.

Initial Sandia mention of the new weapon was made in a progress report of February 18, 1949, wherein it was noted that SLE-7 had been organized as the FM Mk V Division.[18] This Division, in starting design work, was confronted with the general shortage of office and engineering space and facilities at Sandia, caused by the concurrent startup or expansion of other design projects.

Selection of aircraft to carry the TX-5 was discussed in the Steering Committee meeting April 8, 1949. The Air Force program was currently slanted toward use of heavy, long-range bombardment aircraft. Medium-size Navy bombers were still under design, and would not be in production for at least 2 years. Consequently, there was some feeling that current schedules might produce a new bomb before a suitable bomber became available.[19]

As a result of the above meeting, a TX-5 Ad Hoc Panel was appointed by the Military Lisison Committee May 12, 1949.[20] This Panel was composed of representatives of the three Services and, in the course of several meetings and discussions during the summer of 1949, came to feel that the [redacted] DoE b(3)

[redacted] discussed in the July 19, 1949, meeting of the TX-5 Steering Committee. It was agreed that as small a diameter as practicable should be selected, since it would be relatively DoE b(3)

simple to scale upward. A suggestion was made that the bomb be made small enough to fit into a guided missile, but this appeared unduly restrictive. The diameter selected was enough of a departure from previous full-scale detonations to constitute a valid experiment in the laboratory sense, and yet was a size for which some compression computations had been made. [redacted]

DoE b(3)

Throughout the rest of 1949, design studies were made of components such as inflight insertion mechanism, power supplies, and firing sets. Wind-tunnel tests were made of ballistic shapes, and studies made of possible asymmetries which might result from malfunctioning of one or more detonators. [redacted]

DoE b(3)

The general subject of bomb size came in for considerable discussion. Some members of the Steering Committee pointed out that current Rand Corporation studies of nuclear weapons favored use of larger bombs. Other members felt that future emphasis on guided missiles would require small nuclear warheads, and the outcome was a decision to continue work on TX-5 with an eye to eventual stockpile production, but to place more emphasis on larger bombs.

The Military Liaison Committee studied the report of its TX-5 Ad Hoc Panel, and requested the Atomic Energy Commission to delay development of small weapons. The AEC responded with a statement emphasizing the need for small bombs, both to increase flexibility of atomic-weapon usage and to maximize possibility of successful weapon delivery by either aircraft or missiles. A letter to the Military Liaison Committee on January 3, 1950, stated that the General Advisory Committee of the AEC was in favor of developing small or tactical atomic devices and concluded that.

"The TX-5 project is one of the weapon developments in which the interest of the Atomic Energy Commission reflects a general concern that within the next few years the problem of successful delivery of atomic weapons may come to overshadow the problem of increasing the destructive potential of the weapons themselves. The Commission recognizes the primary responsibility of the using forces to set forth desired technical characteristics of weapons, as these characteristics bear on the delivery problem. The Commission remains anxious, however, that its best technical effort be contributed to a solution of this problem in all of its variants which impinge in the area of the Commission's responsibility. The Commission will therefore continue to keep you fully informed of prospective reductions in weapon size and weight, hoping that full advantage will be taken of these forecasts to ease the problems of development of future carriers, a field in which the development cycle is of course substantially longer than the usual cycle of development of the associated weapons."[22]

The Military Liaison Committee wrote to the Division of Military Application February 9, 1950, noting their belief that large-implosion-bomb performance could be considerably improved through use of nuclear design improvements produced by the TX-5 work, and stating that the smaller bomb should be reserved for use in guided missiles.

DoD b(1)

The Division of Military Application stated, in a reply dated March 30, 1950, that the TX-5 nuclear design improvements might obviate any need for larger bombs, but agreed that higher priority would be assigned to use of the TX-5 with future guided missiles.[24]

The ballistic problem was by now well on the way to solution. Extensive experimentation had been undertaken, and a series of 28 different configurations of nose and tail designs had been tested in wind tunnels. A flat nose and large double-wedge fin tail were selected,[28] and the long slender shape of the TX-5 aided materially in producing an aerodynamically satisfactory product.

Deliberate oscillations were created in full-scale drops by use of rocket "kickers" attached to the bomb case, but these oscillations were quickly damped out by the inherent stability of the ballistic shape. A small fin tab was added to impart a slight rotation and improve the trajectory.[29] Weapons were released from various bombers under different conditions. Those dropped from a B-47 at high speeds and low altitudes experienced violent oscillations caused by the air flow around the bomb bay, which imparted a negative pitching moment to the bomb,[30] and this bomber was eventually eliminated as a TX-5 carrier.[31]

[redacted] DOE b(3)

The Fission Weapon Committee of Los Alamos Scientific Laboratory met December 11, 1950, and proposed that experimental small-scale air bursts be detonated in Nevada. [redacted]

DoE b(3)

[redacted]

Mk 5 production was now proceeding at full speed, but encountering procurement difficulties; and a Sandia letter to the Division of Military

Application April 26, 1951, noted that even defense-order classifications could not assure deliveries of needed material and parts when competing with the country's defense buildup. It was concluded that: "It is only by almost superhuman efforts and the full cooperation from all quarters that we can, at this time, even think of delivering the Mk 5 Mod 0 weapon together with its ancillary equipment as early as February of 1952."[32]

The Mk 5 Mod 0 was released for production June 1, 1951.[33] The TX-5 Steering Committee (which had been renamed the TX-N Steering Committee on December 15, 1950, to reflect its broader interest in all implosion-type weapons) approved the design release and then severed its Mk 5 interests by concluding: "It is believed that the Committee's executive functions in the development of the Mk 5 Mod 0 are herewith completed except as specific changes in the weapon are brought to the Committee for approval."[34]

The Mk 5, as released to production June 1, 1951, was a free-fall, air-burst, implosion-type, radar-and-baro-fuzed strategic bomb. Its outside diameter was 43-3/4 inches; length, 128-1/2 inches; and weight, 3300 pounds.

DoE b1

Due to the accelerated schedule, environmental tests were conducted on components, rather than complete weapons. Sandia completed its first assembly and inspection of a Mk 5 Mod 0 in March 1952, and released the weapon for operational service testing and military training. Stockpile entry started soon afterward.

During production of the early Mod 0 Bombs, some design changes were made that were incorporated in the early units. An investigation had been made of methods for quickly attaching and detaching the ~~rear case~~ center band segments (for purposes of weapon servicing), and it was decided to use trunk latches.[35]

The Armed Forces Special Weapons Project reported the existence of sneak circuits in the weapon junction box, and it was found that when the low-burst cable was used, there was a possibility that motor timer clutches could be

unlatched during final assembly or postloading tests.[36] This could cause detonation if the weapon were subsequently released below the altitude at which the arming baro had been set; as a result, expedited investigation and action were undertaken. The low-burst cables were temporarily withdrawn, testers modified, and the low-burst capability restored in April 1952.

The Mk 5 Mod 0 Bomb was discussed in the August 6, 1952, meeting of the Special Weapons Development Board. It was noted that contact resistance of the baroswitches increased with age, but that this could be corrected by cleaning the contacts with solvent, changing the insulating material to eliminate an outgassing problem, and using gold alloy contacts. The inflight insertion mechanism had a tendency to overshoot and cause excessive wear, and a slipping clutch was added to correct this difficulty. The Board accepted the weapon for stockpiling, since corrective action was being taken on these items.[37]

The Mk 5 Mod 1 Bomb resulted from an Armed Forces Special Weapons Project request that cables to supply external power to heaters for batteries and radars be provided to maintain these items at operating temperature in cold weather. Stockpile production of the Mk 5 Mod 1 started November 1952.[38]

On October 13, 1953, Sandia suggested that the inflight insertion mechanism of the Mk 5 Bombs be reworked to incorporate all design changes that had been proposed in this apparatus. At the same time it was suggested that the cartridge mounting be altered to allow a bomb-to-warhead conversion capability, and this proposal was accepted. Design release was effected November 1953 and the revised weapon stockpiled in June 1954 as the Mk 5 Mod 2 Bomb.[39]

A considerable change to the Mk 5 Bomb was made in the Mod 3, which incorporated a new fuze. General dissatisfaction with the complexities of a radar fuze had caused Sandia to examine other methods, and an intensive study of this subject was instituted in mid-1951.[40] The simplest system would have been a pure barometric fuze, but this design had large inherent inaccuracies.[41] An impact fuze offered many advantages, including that of

destruction of the bomb in the event the regular fuze failed, and much effort was expended on this device. This required the use of a fast-firing X-unit, and suitable design work was instituted.[42]

By the fall of 1952, a four-option fuzing system was being studied for Mk 5 application. This system included baro primary, radar primary, timer primary, and contact. Contact backup would be provided for the three air-burst options. The fuzing option would be selected during weapon assembly, through an access port in the skin of the bomb, by insertion of the proper plug in the top of the junction box.

A report on the above proposal was made to the Special Weapons Development Board September 10, 1952. Some members of the Board felt that remote selection of the fuzing option should be possible from the bomber while the weapon was being carried to the target, and other Board members requested that Sandia study the possibility of providing a fifth option, that of a baro-armed radar fuze.[43]

A proposal for a modification of the Mk 5 with the above five fuzing options, together with a suitable fast-firing X-unit, was forwarded to the Division of Military Application on October 22, 1952, and subsequently referred to the Military Liaison Committee.[44] The Committee, in their review of the proposal, requested deletion of the radar fuzing option and asked that inflight selectability be provided for the baro, timer and contact options. This requirement was discussed at the December 10, 1952, meeting of the Special Weapons Development Board, and it was agreed that the new fuze could be designed by May 1953.[45]

In the meantime, the concurrent development of many different fuzes for various weapons had generated concern, within both Sandia and the Armed Forces Special Weapons Project. By January 15, 1953, five such fuzes were currently under design for the Mks 5, 6, 7, 12 and 13. These fuzes required 30 different pieces of support equipment, and it was felt that this proliferation of gear would complicate training, operations, and

logistics. Inasmuch as the Mks 5, 6 and 13 were strategic weapons designed for high-altitude bombing, it was suggested that the fuzes for these weapons be merged in a single design, called Fuze A. This could be a barocontact fuze with a safe-separation timer. The Mks 7 and 12 Bombs could be provided with a fuze for attack of tactical targets, and this would be called Fuze B, with primary fuzing a choice of radar, timer or contact.[46]

The subject was discussed in the January 21 and February 18, 1953, meetings of the Special Weapons Development Board, with a joint presentation being made by Field Command and Sandia Corporation.[47] It was pointed out that Fuze B was essentially the Mk 7 Mod 1 Fuze scheduled to enter stockpile in June 1953, and that this fuze would be available sooner than Fuze A. It was then decided that Fuze B would initially be used in the Mk 5 with a radar-fuzed air burst, pending availability of Fuze A, which would provide a contact capability.[48] The interim use of Fuze B was accepted by the Military Liaison Committee with some misgivings, as it was felt that the ultimate objective for the Mk 5 Bomb was elimination of radars in favor of baro fuzing.[49]

New bomb production requirements through mid-1955 were subsequently approved by the Secretary for Defense and transmitted to the Atomic Energy Commission May 15, 1953.[50] No new production of the Mk 5 Bomb was authorized, and concentration of effort on Fuze A for the Mk 5 was requested. Work on application of Fuze B to the Mk 5 was accordingly dropped, and a Mod change to the Mk 5 with Fuze A application was approved. This became the Mk 5 Mod 3 and was a baro-armed, baro-fuzed system, with contact backup. Mod 3 was design-released February 1954 and War Reserve entry was effected [redacted] The dimensions were the same as previous Mods, but the weight was reduced to 3025 pounds. This was the final modification on the Mk 5 Bomb design.

DOE b(3

GLOSSARY OF MK 5 TERMS

Armed Forces Special Weapons Project -- An interdepartmental agency formed to handle military functions relating to atomic weapons. Activated by memo order from the Secretaries of War and Navy, dated January 29, 1947. The Air Force was represented after passage of the National Security Act of July 29, 1947.

B-29 -- A heavy-bombardment-type, propeller-driven, four-engine aircraft.

Ballistics -- The science which studies the laws governing the motion of projectiles or of bombs dropped from aircraft.

Bridge Wires -- ~~High~~ Low-resistance wires which, ~~when~~ subjected to a high voltage pulse from the weapon X-unit, ~~fuse and burst into flame, thus providing a means of detonating the high explosive sphere.~~ in the detonator (which see) these ignite the explosive elements at the detonator.

Capsule -- The nuclear ~~capsule~~ element of the weapon which, when subjected to compression in the implosion process, becomes supercritical and produces a nuclear reaction.

Committee on Atomic Energy -- Established by the Joint Research and Development Board (which see) in the summer of 1946.

Detonators -- ~~These contain the bridge wires (which see) which, when subjected to a sudden electrical load, burn rapidly and act as a match to apply a flame to various points on the outer surface of the high explosive sphere (which see).~~ Explosive devices which when initiated (see Bridge Wires) by the X-unit ignite the lens charges of the high-explosive sphere (which see).

Division of Military Application -- An AEC office which functions as liaison between the Military and the weapons designers and producers. By provision of the Atomic Energy Act, the Director of this Division is an active member of the Armed Forces.

Fat Man -- Code name for the implosion weapon dropped on Nagasaki, Japan, during World War II. So named for its short, fat silhouette in contradistinction to the early gun-type weapon, which was called the Thin Man (later the Little Boy). The term was extended to include the general designs of early implosion weapons.

General Advisory Committee of the AEC -- The group established by the Atomic Energy Act to provide policy direction for the Atomic Energy Commission.

[redacted] DOE b(3)

High-Explosive Sphere -- The ball of high explosive that surrounds the nuclear capsule and produces the implosion effect when detonated.

pit and is designed to

Implosion-Type Bomb -- A weapon based on the principle discovered by Professor Charles E. Munroe, Washington, D. C. Written up in Scribner's Magazine and the American Journal of Science in 1888, and in Popular Science Monthly in 1900. Rediscovered by Egon Neumann of Germany, who took out German and English patents in 1910-11. The Munroe principle noted that an increased explosive effect was created when an unconfined cylinder of high explosive was hollowed out. In 1920 the Journal of the Society of Chemical Industry (London) stated that "no practical use has apparently been made of this discovery." Suggested by S. H. Neddermeyer at Los Alamos as a means for producing the extremely high pressures required on the capsule of an atomic bomb. Not much attention was paid to the suggestion until it received the backing of John von Neumann and George Kistiakowsky. The same principle was used in the Pacific area in World War II as a means for blasting the occupants of Japanese pill boxes, and for increasing the penetrating effect of shells and warheads.

Joint Research and Development Board -- A replacement for the wartime office of Scientific Research and Development. Established June 6, 1946, by Secretaries of War and Navy to carry on research and development work for new military weapons and equipment.

Kiloton Yield -- A means of measuring the effect of a nuclear explosion by comparing it with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the effect of 1000 tons of high explosive.

Los Alamos Scientific Laboratory -- Founded as the Los Alamos Laboratory in early 1943 as part of the Manhattan Engineer District to undertake weaponization efforts on nuclear devices.

Military Liaison Committee -- A committee established by the Atomic Energy Act of 1946 to advise and consult, on behalf of the Department of Defense, with the AEC on all atomic-energy matters relating to military applications of atomic weapons. Chairman can be any active or retired officer of the Armed Forces. Includes representative or representatives from each department of the Armed Forces.

DoE
b13)

Rand -- Named for Research and Development. A corporation established by the Air Force in early 1946 to study future systems design.

Sandia Research and Development Board -- A joint Sandia Laboratory-Military board formed March 2, 1948, at Sandia Base to provide local guidance on weapons design.

Other design improvements were also being considered. (b)(1), (b)(3)

The scheduling subcommittee of the Sandia Research and Development Board met July 6, 1949 and suggested that a proposed design-release date of February 1950 was overly optimistic and that the production design for the Abee radar could probably not be achieved until mid-1950, thus resulting in availability by the fall of the year. In addition, the ballistics of the lightweight case were proving troublesome, and further wind-tunnel tests and range drops were required. It was recommended that a production date of October 1, 1950 be established for the lightweight case and the new fuzing system.[3]

The schedule was further extended in a letter from the subcommittee to the Board, July 29, 1949, wherein it was proposed that the lightweight case be design-released in May 1950 and stockpiled by February 1, 1951; and that the new fuze be design-released July 1, 1950 and stockpiled by February 1, 1951.[4]

The lightweight case was discussed in the December 21, 1949 meeting of the Sandia Research and Development Board. It was noted that either the riveted or welded design would be selected in the next 3 months, and that the decision would be based on comparative weight, cost, and delivery factors. Consideration was, however, being given to authorizing simultaneous tooling for both types of cases, to save a few months in early production.[5]

The Armed Forces Special Weapons Project notified Sandia January 9, 1950 that improvements to the Mk 4 Bomb were accorded a high priority in the National Military Establishment. It was suggested that perhaps some weight might be ared from the high-explosive sphere case. (b)(1), (b)(3)

radars. (b)(3)

Height-of-burst settings would be adjustable in six steps before weapon assembly, and any one of the six settings could be selected by remote control from the strike aircraft before release. The ranges of these six steps would overlap each other.[16]

Some attention had previously been paid to the possibility of providing inflight insertion. Currently, it was necessary to manually extract two heavy blocks of high explosive, insert the nuclear capsule, replace the high explosive, and button up the assembly. This was tedious and time-consuming, and required that the strike aircraft fly at fairly low altitudes (and thereby at a high rate of fuel consumption) during the insertion process, as the aircraft bomb bays were not pressurized.

The Los Alamos Scientific Laboratory had notified the Division of Military Application that a suitable inflight insertion system could be developed by early 1949.[17] The Division had replied, July 14, 1948, that the Military would gain in safety and logistics if both insertion and extraction in flight could be provided. It was requested that these changes be incorporated as soon as possible.[18]

Los Alamos stated that nuclear efficiency could be improved by better timing of nuclear initiation and that this could be accomplished by use of an external neutron source. (b)(3)

Although this was highly desirable, the Board felt that it would be criticized if production of the Mk 6 was delayed, and suggested that this design revision be held in abeyance.[20]

to arm radars and might be used as primary fuzes if wider burst-height tolerances could be accepted. An improved pressure pickup system was being designed, and such fuzing systems as time of fall, time of flight, flight distance, contact, and pyrotechnic were all being investigated.[27]

The Division of Military Application notified Sandia Field Office, July 30, 1951, that about 20 percent of production Abee's currently being tested by the Air Force Special Weapons Center were failing due to various causes. It was noted that the Department of Defense had concluded that the Abee was not suitable and that baroswitches would have to be used to fire the Mk 6 Bomb.[28]

The problem was referred to Sandia, which replied, July 31, 1951, that recent Air Force experiments on the operation of the Abee motor timer had been conducted. This operation required that the radars be jammed, and the test was completed satisfactorily. Sandia had been informed that this test had been interpreted to mean that the bomb was extremely vulnerable to jamming. It was pointed out, too, that 4-N bombs had been used. Sandia felt that the Abee, as it existed, represented a distinct improvement over the Archie from both operational and reliability standpoints.[29]

Meanwhile the Mk 6 Mod 0 Bomb, which had been design-released May 15, 1951, achieved early production in July 1951.[30] The bomb was subsequently stockpiled, but not accepted for operational use by the Military.

Field Command notified Sandia August 1, 1951, that use of the Mk 4 baroswitch fuzing system, which was scheduled for use in the Mk 6, required an extremely complicated and arduous process. Theoretically, this system was accurate when precisely used but, under the most carefully controlled field conditions, this accuracy was halved. It was urged that an improved system be provided for the Mk 6 Bomb.[31]

The need for early introduction of this modified baroswitch sensing system was discussed in the August 8, 1951 meeting of the Sandia Weapons Development Board.

in accordance with current procedures.[33] To make matters worse, when these two units were again examined upon return from the test (this mission was aborted due to weather), they both failed to pass the standard assembly-type retest. This resulted in examination of a larger number of stockpiled Abee's, using stockpile testers and revised Sandia procedures. Results indicated that about half of these Abee's would fail to pass the test, and Sandia investigations confirmed these findings.[34]

The Sandia Weapons Development Board met September 26, 1951, and continued its appraisal of the Abee radar. It was pointed out that inconsistent results from tests conducted on the same radar at different locations were being reported, and it was suggested that the various pieces of test equipment be compared. It was noted that Abee drop tests had been conducted, and that some radar failures had been reported, but that no dud bombs had resulted. It was felt that, in the event of national emergency, the baroswitches could be used as primary fuzes, but the Military members of the Board stated that this expedient was unacceptable for other than the high-burst option of the Mk 6.

Sandia assigned an overriding priority to the problem, and formed a task group of the most highly qualified Sandia and contractor personnel to investigate all phases of the problem. This group was to issue a formal report of its findings by November 1, 1951.[35] The program was named the GF (for Grouped Forces, code-named Greenfruit) Task Group. The GF task was to conduct a complete evaluation of the Abee, recommend measures to correct existing deficiencies, and implement the necessary corrective measures.[36]

Early investigation by the GF Group discovered that a delay in the transmitter/receiver keep-alive circuit allowed a large transmitted signal breakthrough for the first 200 transmitted pulses and that this caused excessive crystal burnout. This was corrected by a minor wiring change in the unit which provided advance arming of the keep-alive electrode.

The transmitter tube was found to have a slow leak which was traced to a defective ceramic cathode seal and was replaced by an improved arch glass design.[37] The lack of correlation between production-line tests of the Abee and subsequent testing in the field, involved the use of different testing devices which contributed to the problem, and action was taken to revise these tester designs.

It was found that the transmitter/receiver tube was subject to frequent breakage, aggravated by temperature cycling of the tubes in their mounts. Detailed examination showed that high stresses were created and the tube mountings were redesigned. Failure of the ballast tubes was traced to faulty mechanical support of the tube filament. A rigid system of inspection was instituted and tube redesign was started.

Unstable ranging and relay chatter was reported which caused reduced ranging accuracy. A circuit change was made, providing parasitic suppressors to the range deck.[38] The final GF evaluation report, issued in late 1951, recommended that the revised Abee be released to stockpile. Acceptable quality had been achieved, together with good fuzing accuracy at attitude angles up to 28 degrees from the vertical.[39]

Sandia presented Report SC2319(TR), Engineering Evaluation of the Design of the Mk 6 Mod 0 Weapon, to the April 16, 1952 meeting of the Sandia Weapons Development Board. The Board felt that no formal action was necessary. It was pointed out that the Mk 6 Mod 0 would soon cease to exist, as parts were already being procured for the Mk 6 Mod 2 Bomb.[40]

The report was published August 15, 1952. The Mk 6 Mod 0 Bomb was 61 inches in diameter, 128 inches long, and weighed 8500 pounds. It was suspended by a single lug from the internal bomb bays of the B-29, B-36, B-47, B-50, B-52, AJ, A2J and A3D aircraft. (b)(1), (b)(3)

The manual insertion mechanism was the same as that used in the Mk 4 Bomb.

The Mk 6 Mod 0 had two interchangeable, lightweight, aluminum-alloy ballistic cases, one of welded and the other of riveted construction. The bomb was provided with improved barometric pressure sensing and dynamic stability by spoiler bands placed around the central portion of the ballistic case. The Abee radar fuze incorporated a remotely controlled range-setting feature plus circuit refinements that made the bomb more resistant to enemy countermeasures. (b)(1), (b)(3)

Mk 6 Mod 1 Bomb

The Mk 6 Mod 0 was the start of a development effort which was to continue for several years. Technological advances were breaking through on all fronts, both nuclear and nonnuclear, and including the carriers of the bomb. One of

the early changes provided optional use of the Albert radar as an alternate to the Abee radar.

The Albert radar had been started into development, and it had been hoped that units would be available by July 1950. However, the device proved difficult to design and fabricate, and its operational details were not firmed up until mid-1951, when it emerged as a device using different radiated frequencies than the Abee and providing higher transmitted power. (b)(1), (b)(3)

Use of the Albert required a different bomb antenna, and a new nose plate was developed for use with either Abee or Albert. This nose plate incorporated horn-type antennas for the Albert, while a discone antenna was used with the Abee.

Sandia notified the Albert development contractor that a GF-type program should be established to evaluate radar quality prior to production and to provide any steps necessary to achieve a fully satisfactory unit for military use. Thus a program called 3-E (for MC-3 Evaluation) was established in late 1951.[42]

The Albert was designed-released in February 1952 and assembly of units was started. It had been hoped that the 3-E Group could issue a formal report by September 1952, but discrepancies were revealed by the investigation. These problems concerned sensitivity, compatibility, vacuum-tube difficulties, and some mechanical troubles. (b)(1), (b)(3)

It had been discovered that full ranging capability within 10 seconds after application of inverter power was not guaranteed, even with preconditioning.[43]

weapon development was recognized. The Navy was prepared to accept the improved manual inflight insertion system.[47]

Thus, incorporation of the change into stockpile was urged, and schedules were established calling for first delivery in January 1952.[48] (b)(3)

For ease in assembly, the horn antennas were installed on the sphere case rather than on the nose plate as in the previous models, and this eliminated the need for connecting the antenna cables during reassembly of the nose plate after nuclear insertion. The Mk 6 Mod 2 Bomb entered stockpile in January 1952.

Report SC2484(TR), Engineering Evaluation of the Mk 6 Mod 3 Bomb, was dated November 17, 1952, but the report also covered the Mod 2. (b)(3)

Mk 6 Mod 3 Bomb

Drop tests of the Mk 6 Mod 2 configuration brought unexpected results. It was found that the radars were firing prematurely, as soon as they were armed by the baroswitches. When weapons were tested in the laboratory, the same thing happened, and investigation disclosed that the radars were "ringing" off the nose cavity of the bomb itself.

It was found that a quarter-inch clearance between the horn antenna and the nose plate of the bomb permitted radio leakage into the cavity between the nose plate and the rest of the bomb. The microwave signal reflected back and forth within this cavity, and then leaked back into the antenna and fired the radar relays.[50]

There were several possible solutions, such as adding absorbent material to the bomb nose or making the nose of plastic material, but the simplest one was to revert to the original configuration by installing the antennas on the nose plate rather than the sphere case. This meant that the antenna cables had to be disconnected for removal of the nose plate and reconnected in flight after nuclear insertion, but this was not considered to be a serious problem and the change was quickly made.[51]

The altered weapon became the Mk 6 Mod 3, which entered stockpile in July 1952.[52] By November of that year, all Mk 6's had been converted to the Mod 3 configuration.

Mk 6 Mod 4 Bomb

This change added a warmup cable. This cable permitted application of 28-volt direct current from an external power source to operate the heaters in the radars and battery cases. It was found that after the weapon had been stored at low temperatures, preheating of these components was necessary to ensure that they would perform properly during checkout tests. After the bomb had been loaded into the strike aircraft, the heaters could be operated through the aircraft pullout cable, using aircraft power. The Mk 6 Mod 4 entered stockpile in November 1952.[53]

Mk 6 Mod 5 Bomb

The Mod 5 incorporated a baroswitch fuze. The Military had for some time advocated replacement of the radars with an all-barometric fuzing system.[54] Their reasons were based not only on the difficulties which had been experienced with

The design also used nickel-cadmium batteries or Mk 2 Power Supply. These batteries replaced a lead-acid design and provided greatly improved operational readiness, since they could be charged in less time and be stored in the charged condition for longer periods. The Mk 6 Mod 5 Bomb entered stockpile in May 1953.

Mk 6 Mod 6 Bomb

The broad objectives of the Mod 6 were to provide contact fuzing and a Mach-insensitive barometric sensing system. This latter system was one which the Military had been requesting for some time.[60] It would provide the correct atmospheric pressure to the baroswitches regardless of the rate of fall of the weapon. Corrections to baroswitch settings were required to compensate for the varying effect of air flow past baroswitch ports at different Mach numbers. Making this correction was troublesome as it involved use of complicated tables incorporating the latest meteorological data, estimating the speed of weapon fall at the altitude at which the baroswitches were to close, and accurately controlling the speed and altitude of the strike aircraft at the time of drop. These problems were discussed at the August 8, 1951 meeting of the Sandia Weapons Development Board, and a formal recommendation was made that development emphasis be continued on a Mach-insensitive design.[32]

The emphasis was applied, but solutions to the problem were found to be quite elusive.[61] Early experiments with drag cones and trailing probes showed some promise. These devices placed the pressure pickup far enough behind the falling bomb to be relatively free of the effect of air flowing past it.

The drag cone showed especially good statistical reliability when the pressure orifices were located at the end of an 18-foot length of flexible hose attached to the bomb tail plate. This proved to be a difficult mechanical installation, however, as the buffeting effect of the air exerted forces on the hose which exceeded the breaking strength of the material, even when stainless-steel hose was tested. Deployment of the device as the bomb fell away from the carrying

Sandia presented Report SC3271(TR), Design Description and Status Report of the Station 124 Pressure Sensing System for the TX-6-X4 Weapon, to the March 31, 1954 meeting of the Special Weapons Development Board. This report described the pressure-sensing system, discussed its capabilities, and summarized the test results. It appeared possible to use a single pressure offset when determining the baroswitch setting, and accept some degradation for those few burst heights (about 2 percent) which would be made at speeds higher than Mach 0.9.[68]

Sandia presented Report SC2540(TR), Engineering Evaluation of the Mk 6 Mod 6 Bomb with Mk 13 Mod 0 Fuze, to the January 12, 1955 meeting of the Special Weapons Development Board. Basic changes included the Mach-insensitive pressure-sensing system and a contact fuze. Contact-fuze tests had included 75-millimeter gun firings to simulate a spike impact, and sled tests to measure sensitivity of the system to rain impact. The Mk 6 Mod 6 entered stockpile in January 1955, and all previous modifications were converted to this design.

Stability of the bomb was satisfactory, except for drops made from B-47 aircraft at low altitudes and high speeds. In these cases the weapon pitched considerably upon release, due to the aerodynamics of the airplane and the bomb. This particular delivery required that bombing-table corrections be made to achieve the desired ballistic accuracy. All components and systems operated satisfactorily during fuzing and firing drop tests.[69]

The bomb diameter was 61 inches, its length 128 inches, and its weight 8170 pounds. (b)(1), (b)(3)

Prior to takeoff, aircraft power was supplied to timer and battery heaters and trigger-circuit filaments. (b)(1), (b)(3)

The safing switch was placed to the arm position.

At bomb release, the pullout switches closed, starting the safe-separation timer and the inverters, and switching the trigger-circuit filaments from aircraft power to internal battery power. At the end of the preset safe-separation time, battery power was provided to the arming relay, which could not operate until the arming baroswitch closed and furnished a path to ground. (b)(1), (b)(3)

Operation of the arm relay then connected the inverter output to the firing-set charging circuits. The firing set completed its charge in about 0.5 second. Three seconds after safe-separation time, another switch in the safe-separation timer closed, completing the fuzing-baroswitch ground circuit, and the weapon was now ready for air-burst detonation.

If the fuzing baroswitch had been set for air burst, it closed at the predetermined altitude, forming a negative pulse which was applied to the trigger-circuit cathodes, firing both thyratrons. The output pulse of the trigger circuit fired both gaps, discharging the main bank condenser energy into the detonator bridge wires, with resultant weapon detonation. If the air-burst fuze failed, detonation occurred at impact.

If the fuzing baroswitch had been set for contact detonation, or if the air-burst fuze failed, impact of the weapon with the target resulted in detonation. The impact caused the crystals to generate a voltage which was applied to both thyratron grids, and the resultant firing of either thyratron initiated the firing sequence.[70]

(b)(3)

The Board met December 11, 1951 and accepted the proposed design.[60] Since the weapon was now no longer interchangeable with other Mk 6 Bombs--a different capsule being required--it was designated the Mk 18.

Only pit and capsule were affected, so most of the development work was carried out by Los Alamos. (b)(3)

implosion system. However, upon cancellation of the TX-13 in August 1954, the TX-20 program was similarly deleted.

Retirement

With the development of thermonuclear weapons, as well as fission devices of more advanced design, the Mk 6 became obsolete. Removal from stockpile started in 1957 and by July 1962 all Mk 6 units had been retired.

History of the Mk 7 Weapon

The Mk 7 weapon had its beginning in studies made by Group W-4 of the Los Alamos Scientific Laboratory in late 1949 and early 1950. Results of these researches were presented to the May 26, 1950, meeting of the TX-5 Steering Committee by W-4, who noted that the Group was interested in the development of small-diameter bombs for tactical military use.

(b)(3), (b)(1)

A weight of 1900 pounds (compared to 3300 for the Mk 5) was predicted, and a maximum outer bomb diameter of 32 inches.[1]

Detail studies were then started. While these were in progress, the conflict in Korea deepened and resulted in a July 11, 1950, teletype

RESTRICTED DATA
SECRET

from the Division of Military Application which stated:

(b)(3)

Submission of your plan is requested in part or in whole as it is received.[2]

(b)(3)

A TX-5 Steering Committee meeting was held July 17, 1950, followed by a joint meeting August 2, 1950, with the Sandia Weapons Development Board.[4]

(b)(3)

(b)(3) The streamlined shape of the bomb suggested the practicality of external carriage, but this required a complicated nuclear insertion system and made it difficult to retain the nuclear components in the event the bomb had to be jettisoned. Due to the radical change in shape from previous atomic bombs, the ballistics problem required attention, both from the standpoint of external carriage and the release trajectory of the bomb. Aircraft compatibility would entail a major effort, as a variety of tactical airplanes were being designed and produced.[7] It had been proposed that the external case be developed by an aircraft company, and Sandia had already conferred with several West Coast manufacturers. Of these, Douglas Aircraft Company appeared a logical choice, with both space and cleared personnel available, and a contract was subsequently awarded.[8]

SECRET

UNCLASSIFIED

Inflight insertion problems required study.[9] The purpose of inflight insertion was to prevent nuclear detonation from occurring during take-off or landing, reduce nuclear contamination in the event of accident, and allow salvage of nuclear material. Sandia prepared both forward and rear insertion proposals.

(b)(3)

This second type resulted in a considerable shift of the bomb center of gravity during insertion, and the initial decision was to use the forward insertion design. Later, it was decided to place the relatively heavy cartridge at the forward face of the sphere assembly and a horizontally operating insertion mechanism aft of the sphere. Controls were installed in the cockpit of the carrying aircraft, so that insertion or retraction of the capsule could be remotely accomplished in flight.

It was felt that the fuzing system might require attention, but not until information was received from the Military concerning the method of bomb combat use. The firing system would be similar to that used in the TX-5. It was proposed that the bomb length be about six times the diameter and it was predicted that this shape would attain a speed of Mach 1.2 to 1.5 during the bomb drop.

(b)(3)

Closer estimation of the weight placed this figure at 1680 pounds.

RESTRICTED DATA
SECRET

UNCLASSIFIED

An August 9, 1950, memorandum from the Military Liaison Committee to the Division of Military Application stated that the Joint Chiefs of Staff had established a requirement for air-burst atomic bombs sufficiently light in weight and small in cross section to be carried by high-speed tactical planes.

(b)(3)

The weapon was to be used by fighter or light bombardment aircraft in attacking tactical targets, with the bomb normally being carried externally.

(b)(3)

The bomb was not to exceed 2000 pounds in weight nor 33 inches in diameter and was to have a configuration which would reduce aerodynamic drag to a minimum. Exterior ballistics should allow reproducible trajectories, and the bomb was to be aerodynamically stable. The fuzing system was to permit freedom to select alternate targets at varying altitudes while en route, be relatively nonsusceptible to enemy countermeasures, and allow both air burst and an approximately zero height of burst. However, this last requirement was not to delay the early availability of the bomb.

The bomb was to have a means of nuclear safing, such as remotely controlled inflight insertion and extraction, require only simple adjustment or monitoring, and be capable of release at subsonic and supersonic speeds. It was to be designed for ease of assembly in forward-base areas or on board ship, and be capable of storage for periods up to 6 months in these locations. The bomb was to be able to withstand stresses created by carriage on fighter-aircraft wing pylons and bomb racks. Normal operation was to be possible under icing conditions and throughout a temperature range from -65°F to +165°F.[12]

(b)(3)

Two types of bomb suspension were considered, a three-hook rack with one lug forward and two lugs aft, and a two-lug design.[13]

A 14-percent scale model was built and tested at the Cooperative Wind Tunnel at the California Institute of Technology. A drag coefficient of less than 0.042 was reported, as compared to 0.54 for the Mk 4. This indicated the general superiority of the long, thin shape, and it was proposed that the bomb length be increased to 192 inches, the maximum possible without the bomb striking the runway on takeoff or landing. To provide more ground clearance, it was decided to use three fins instead of four, and to make the lower fin retractable. Later, the bomb was shortened to about its originally proposed length, or 183 inches, to permit carriage of the weapon on certain Navy aircraft.[14]

(b)(3)

Douglas Aircraft Company reported development of a family of shapes that appeared satisfactory from below sonic speed up to Mach 1.2. Meetings with Air Force representatives underscored the emerging need for tactical nuclear weapons, and orders were issued for early modification of a group of Tactical Air Command F-84E airplanes to carry the TX-7.

Completion of wind-tunnel model tests at speeds up to Mach 1.2 demonstrated that the shapes possessed adequate stability, and full-scale drops were started. The first such drop at the Salton Sea Test Base resulted in the bomb's going into gyrations of 45 degrees and shedding its tail assembly, while another drop produced severe pitching action. Immediate and intensive investigation was undertaken, and it was found that fin misalignment caused circular wobbling of the tail, and that this instability was augmented when the misalignment was enough to cause

the bomb body to rotate at the same rate as its natural pitching frequency. The problem was solved by holding the fin alignment to ±1/2 degree, and by stiffening the fixed fins by base angles and the retractable fin by guide rollers.[16] Spin tabs were added to generate a roll rate which would always be greater than the natural pitch frequency.

Terminal velocity during full-scale drops was found to be about Mach 1.0, in an unstable or buffeting region, and it was felt necessary to reduce this speed. A drogue-chute design was proposed that incorporated six small fins to which were attached risers of a 36-inch-diameter parachute. Experimentation, however, showed that operation was strongly affected by relatively minor changes in wind, air density, airspeed, and release altitude.

Dive brakes were tested and proved satisfactory. The first such design had an area of 87 square inches, causing too much drag, and the area was reduced to 70 square inches. The length of the fin, initially 26 inches, was increased to 30-1/2 inches for improved stability. This was found to provide insufficient clearance with carrying aircraft, and the length was eventually established at 29 inches.

The foregoing studies were interwoven with the problem of providing an accurate barometric pressure-sensing system for bomb altitude determination. Nose probes were tested, but could not be made long enough to reach unaffected pressure regions ahead of the falling bomb. Trailing probes were subjected to excessive whipping in flight and to freezing of the mechanism. Eventually, the problem was alleviated by the reduced speed of fall resulting from the use of dive brakes. Studies conducted at the Salton Sea Test Base resulted in locating the pressure ports on the bomb case 125 inches aft of the nose.

Flight tests were conducted on the F-84 aircraft at Muroc Dry Lake, California. The TX-7 store was installed on the right wing pylon and a

(b)(3)

This order was amended September 4, 1951, to require production-quality fuzes. Sandia noted that this second program would continue to divert engineering effort, already severely affected by the 7N work, and delay regular Mk 7 production.[28] Sandia was subsequently relieved of work in connection with this second 7N program,[29] but later was requested to inspect and certify some of the 7N components used in the program.[30]

(b)(3)

Sandia pointed out that regular Mk 7 Bombs would be available soon after this date, and this third program was canceled.[31]

The Mk 7 Mod 1 Bomb resulted from a request from the Armed Forces Special Weapons Project that external power be supplied to battery and radar heaters to create proper operating temperatures in cold weather.[32] Stockpile production of this modification started November 1952.

It was felt that the Mk 7 Nose, which formed a radome for the radars, might ice up during external carriage of the bomb. Several methods were studied, including use of a pulsating rubber boot or deicing fluid. Tests showed that a neoprene-coated radome would do the job and at the same time reduce rain erosion damage, and this change was adopted. The carriage of the Mk 7 on many types of aircraft resulted in a requirement for different fin positions, and the design was accordingly amended so

Fuze B was subsequently designed with a timer that could be used to arm the radars (providing safe-separation time) or as a primary fuze by itself. Radar air burst was retained and a contact fuze added which could be used as cleanup or as a primary fuze. An externally accessible remote-setting device permitted preflight selection of safe-separation times coupled with radar ranges.

Tests had shown that boat-tail fins produced increased stability with little or no increase in drag, and this fin design was adopted.[37] Other methods of retarding the speed of bomb drop had been studied, such as parachutes or rotochutes (freely rotating vanes), but these latter designs did not prove entirely satisfactory from the standpoint of bombing accuracy and effectiveness of retardation.

The Mk 7 Mod 3 Bomb entered production June 1953 with the new fuze design and improved ballistic characteristics. The fins were made nonretractable, but could be removed for storage. A visual port was provided in the body of the bomb so that the position of the safety switch (which isolated the battery from the bomb circuits) could be checked. In previous bomb modifications, this check had been made from the cockpit of the carrying aircraft, using a special tester. Weight was reduced slightly, to 1620 pounds.

(b)(1), (b)(3)

This change was incorporated in the Mk 7 Mod 4 Bomb, which also provided a universal warhead that could be used for both bombs and missiles, and which possessed a quick-disconnect radome. The Mod 4 was design-released in March and stockpiled December 1954

(b)(1), (b)(3)

It was found that ejector forces exerted by the Aero 7A Bomb Rack created shock loads which affected timers and radars. Shock-absorption pads were installed to protect the radars, and new shock mounts were designed for the timers. These changes were released October 1956 and the resulting units were stockpiled June 1957 as the Mk 7 Mod 5 Bomb.

(b)(1), (b)(3)

Sandia suggested, February 15, 1960, that additional safing be provided for Mk 7 Bombs being maintained in alert status. Charging of the X-unit would be prevented until the weapon had experienced a normal trajectory. Sandia was requested to provide such design January 25, 1961, and it was suggested that components being produced for the Mk 43 Bomb be used for this purpose.

Wind-tunnel tests of the design gave satisfactory results, but flyaround tests resulted in erratic operation on one type of aircraft. The pressure-switch setting was slightly altered, and the use of a higher spoiler in front of the pressure-switch port produced good results. The change entered production in July 1961 as the Mk 7 Mod 7 Bomb.

Permissive Arming Link devices were released for use in the Mods 5 and 7 Bombs, with production being initiated in February 1963. The Mk 7 Mod 5 became the Mk 7 Mod 8, and the Mk 7 Mod 7 became the Mk 7 Mod 9.

Glossary of Mk 7 Bomb Terms

Armed Forces Special Weapons Project -- An interdepartmental agency formed to handle military functions related to atomic weapons.

Ballistics -- The science governing motion of projectiles or bombs dropped from aircraft.

Barometric Fuzing -- Use of a pressure switch actuated by increasing air pressure as the weapon falls in its trajectory to institute weapon fuzing.

Buffeting -- Excessive vibration of a falling bomb caused by weapon instability. Also vibration of a bomb carried externally on aircraft.

Buster-Jangle -- Tests of atomic devices at the Nevada Test Site. Series of seven shots, starting October 22 and ending November 29, 1951.

Capsule -- The nuclear ~~assembly~~ element of an atomic weapon which, when subjected to compression in the implosion process, becomes supercritical and produces a nuclear reaction.

Capsule Retention -- A method of retaining the nuclear capsule while allowing jettisoning of the weapon; of prime importance in the early days of nuclear weaponry, due to scarcity of nuclear material.

Cartridge -- An assembly, generally containing fuzing and firing system elements, which can be inserted and removed from an atomic weapon in the manner of a cartridge being inserted or removed from the chamber of a rifle.

Compatibility Tests -- Tests to prove whether or not the weapon can be easily installed, tested and released from its specified carriers.

Contact Fuze -- A fuze that detonates the weapon by contact with the ground or the target.

Core -- See Capsule.

Detonators -- ~~Devices containing bridge wires which, when subjected to an electrical current, burn rapidly and act as a match to apply a flame to various points on the outer surface of the high explosive~~ explosive devices which when initiated by the current, ignite the lens charge of the high explosive sphere.

Dive Brakes -- ~~Projecting~~ plates, generally at the tail of a weapon, which, when released, slow its fall through the air. Purpose is to reduce the rate of fall (velocity) to well below the speed of Mach 1.0, which was a highly unstable speed region for the early bombs.

Mk 7/ALIAS BETTY

4/16/51	Joints Chiefs of Staff request adaption of atomic warhead for underwater detonation.
10/9/51	Naval Ordnance Laboratory reports feasibility of project.
2/6/52	Military Liaison Committee reports that Joint Chiefs of Staff have established a requirement for development of an atomic bomb capable of inflicting lethal damage to submerged high-speed submarines.
4/14/52	Division of Military Application approves division of responsibilities for project.
6/11/52	Ad Hoc Committee meets and selects XW-7 Warhead.
11/12/52	Military Liaison Committee approves military characteristics for project.
2/54	Production authorization issued.
7/29/54	Mk 7/ALIAS BETTY Warhead installation design released.
6/55	Mk 7/ALIAS BETTY achieves production.

Mk 7/BOAR

2/1/51	Military Liaison Committee states that Bureau of Ordnance will develop an air-launched free-flight rocket capable of carrying an atomic weapon.
6/6/52	Initial meeting of project Steering Committee. Decision made to start active development, using either Mk 7 or Mk 12 Warheads.
7/22/52	Ad Hoc Committee meets and favors Mk 7 Warhead.
10/21/52	Military Liaison Committee establishes military requirements.
11/54	Mk 7/BOAR Warhead installation design released.
10/24/56	Final Development Report issued. No production authorized.

The Mk 7 Mod 0 Warhead was released for production May 1952, and first appeared in stockpile August 1954, as a result of site conversion of bombs to warheads.

(b)(3), (b)(1)

contact bursts were produced by a barium-titanate fuze.

The design was suitable for use with the CORPORAL missile, and also with the HONEST JOHN, which had been added to the list. Its use with certain missiles involved increased g-loadings produced by high accelerations, and it was felt necessary to provide a dual-motor nuclear insertion mechanism. The bomb had a flange, which was removed when the bomb was converted to a warhead. A new forward shape was proposed that would be applicable to the BOAR project and the Mk 7 Bomb, together with a new fuze that reduced the number of radars and incorporated a new barometric-switch design.

All the above modifications were included in a single program which, however, was disapproved by the Special Weapons Development Board.[9] A universal design was subsequently incorporated in the Mk 7 Mod 1 Warhead which was design-released November 1953, and which appeared in stockpile March 1955 as a result of site conversion of bombs to warheads. This design provided a warhead that was fully interchangeable between bombs and missiles.[10] A Mk 7 Mod 2 Warhead with dual-motor insertion mechanism was design-released July 1955, and achieved production October 1956 for use in the NIKE-B and BOAR weapons. This warhead could not be converted to bomb use. The Mk 7 Mod 3 warhead was provided with a permissive arming link, was design-released July 1963, and achieved production in August.

(b)(3)

History of Gun-Type Bombs and Warheads

Mk 8 Bomb

The gun method of assembling nuclear material, used in the wartime Little Boy design, was the first atomic weapon system to be devised, predating the establishment of the Los Alamos Laboratory. The method was nuclearly inefficient and was largely ignored for a time after the end of World War II, while interest centered on implosion techniques.

(b)(1), (b)(3)

At this time, the Los Alamos Scientific Laboratory was fully occupied in the above-mentioned study of improvements in implosion devices, and suggested that the task of developing a water-penetrating weapon (which probably would use gun techniques) could best be accomplished by a military group. No immediate action was taken on this suggestion, but the subject was briefly examined by the Z Division of Los Alamos in late 1946 and early 1947.

(b)(1), (b)(3)

The topic was subsequently discussed in a meeting of the Weapons Subcommittee of the AEC General Advisory Committee, and a decision made May 15, 1947 that consideration of a penetrating weapon be postponed.[4]

Meanwhile, however, the Military Liaison Committee had been discussing the general subject of subsurface atomic weapons. At the instigation of the Navy member, Rear Admiral William S. Parsons (who had armed the wartime gun-type Little Boy for

its historic drop on Hiroshima), Section ReM of the Navy's Bureau of Ordnance, prepared preliminary sketches of a penetrating gun device.

At about the same time, other groups were considering the same subject. The Joint Research and Development Board had established a Committee on Atomic Energy, and the subject of penetrating weapons was discussed in the October 2, 1947 meeting of this Committee. It was urged that serious consideration be given to the development of a gun-type device suitable for penetration use. Since the AEC weapon laboratories were already fully occupied with other high-priority work, the Committee recommended that the facilities of the Bureau of Ordnance be used.[5]

The Division of Military Application had also been considering the advisability of invoking the assistance of the military services in the development of penetrating weapons. Los Alamos had noted that gun systems were inherently inefficient, and expressed an opinion that the weapons laboratories should continue to concentrate on design of implosion devices.[6] Thus the Military Liaison Committee was requested to assign mechanical design of a gun-type penetration weapon to the Bureau of Ordnance.[7]

These several requests, all in the same vein, were presented for consideration to the Military Liaison Committee which, April 9, 1948, requested the Atomic Energy Commission to undertake development of a penetrating-type weapon, using the facilities of the Bureau of Ordnance.[8] This request was formally presented to the Bureau April 27, 1948, and accepted.[9] A code name of "Minnie" was initially assigned to the project, but was later found to have been used for a Bureau of Ships propulsion project and, in mid-July 1948, the name was changed to "LC" (a follow-on term to "LB," for the Little Boy), and which came to be commonly written as "Elsie."[10] That the Elsie program was considered a matter of some interest to the Military was indicated in a May 6, 1948 meeting of the Sandia Research and Development Board in which the project was assigned top priority, second only to the schedule for getting the Mk 4 Bomb into full-scale production.

The Bureau of Ordnance issued detailed work assignments. The Naval Ordnance Laboratory would be responsible for developing suitable pyrotechnic delay fuzes.

The Naval Ordnance Test Station would study external ballistics and design the tail. The Naval Powder Factory would investigate powder development. The Naval Ordnance Plant would handle much of the manufacturing and testing program, and when this location was subsequently closed, the work would be transferred to the Naval Proving Grounds and the Naval Gun Factory. Section ReM of the Bureau of Ordnance would provide overall design controls, including the task of guaranteeing survival of the nuclear assembly under impact conditions.

The development program would proceed in three overlapping phases. Feasibility and preliminary design studies would outline the most promising general design characteristics of the weapon, and these were scheduled for completion January 1, 1949. The second phase, covering experimental development and testing of prototype weapon design, would be completed a year later. The third phase, manufacture of prototype weapons, would be finished in another year, or January 1, 1951.

(b)(3)

The studies advanced rapidly and, by September 3, 1948, the Bureau of Ordnance could report that the design appeared feasible and that a weapon could probably be devised that would function satisfactorily after impact on water, and possibly after impact on hard surfaces which the weapon might encounter beneath the surface of the water.[11] It was initially felt that the fuze should be actuated at impact and have a delay of 1 to 2 minutes before bomb detonation, but it was later decided that a more reliable bomb would be created if the fuze action were initiated at time of release of the bomb from the carrying aircraft.

The diameter of the bomb would be about 14 inches and the weight would be about 3000 pounds, as compared to 28 inches and 8900 pounds for the Little Boy. These reductions were due to the more compact nuclear assembly and a decrease in the thickness of the bomb case. The shape would be roughly cylindrical, with a flat nose for good penetration characteristics, and the bomb would attain a maximum impact velocity of 1500 feet per second. The minimum release altitude would be 500 feet, to give the bomb enough time during its fall to assume proper entry attitude, and there would be no restriction on maximum release altitude. It was felt that three separate and independent fuzes should be used, to provide adequate relisbility. A meeting was held October 25 and 26, 1948, with Los Alamos assuming the task of developing impact-resistant initiators.[12]

An extensive series of tests was performed. The first group included 174 half-scale bombs of 6.25-inch diameter. These were fabricated in 49 different configurations, and were impacted against targets of steel and concrete at different angles, striking velocities, and missile temperatures ranging from -65°F to +165°F.

(b)(3)

Following the above, some 38 full-scale impact tests were conducted, to confirm the half-scale results. Interior ballistic tests were performed, to check the burning rate of various propellants and the behavior of the missile in the gun barrel. As fuze components became available, they were subjected to the shock produced by firing from a 14.25-inch-diameter railway gun.

Two series of wind-tunnel tests were held, one at the University of Minnesota to obtain aerodynamic coefficients of various tail configurations, and the other at the California Institute of Technology Cooperative Wind Tunnel to evaluate aerodynamic characteristics of five basic designs.

directive was issued August 30, 1950, accompanied by a request that the facilities of the Bureau of Ordnance be used to the fullest extent possible.[17] At this time, the Elsie was assigned nomenclature of TX-8.[18]

An intensive study had been undertaken of changes required to allow external carriage of the TX-8. There were several reasons why these changes were necessary. For one, the fuze system had been designed to operate under protected bomb-bay conditions. For another, the shape of the TX-8, with its blunt nose, caused excessive drag, especially at high speeds.

(b)(3)

It was obvious that this would require considerable study, and it was suggested that the Bureau of Ordnance establish a parallel program for the development of a Mk II Elsie suitable for either internal or external suspension, while work continued on an internally carried TX-8.[19]

The Bureau made a survey and reported that the existing shape of the TX-8 was adequate for subsonic external carriage if some minor changes were made to the tail design,[20] and the shape could be carried in the space available under the centerline of the F4U, AD and A2D airplanes. It was noted that development of a shape for external carriage at supersonic velocities would require additional study and development, and this effort would be of interest in connection with a recent proposal that an XW-8 Warhead be fitted to a guided missile. Subsequently, October 3, 1950, the Division of Military Application authorized development of an externally carried TX-8 with subsonic aircraft and development of a new bomb (the TX-11) for high-speed external carriage.[21]

Meanwhile, the Armed Forces Special Weapons Project had been drawing up a paper specifying the desired military and technical characteristics of penetrating-type weapons.

(b)(1), (b)(3)

This paper was circulated for comment to Sandia and Los Alamos as well as the Military, and was subjected to a critical review.[23] The formal issue of the characteristics on November 10, 1950, however, retained the release speed requirement and noted that the bomb should function reliably when released at any altitude up to 50,000 feet and survive impacts on water, reinforced concrete, and--hopefully--thin steel plate.

(b)(3)

The November 22, 1950 meeting of the Sandia Weapons Development Board reviewed the overall gun-type weapons program, which now included the TX-9, TX-10, and TX-11, in addition to the TX-8. It was noted that the TX-8 was composed of three main parts: The nose, the tail, and the clamping ring which joined them. The bomb diameter had been fixed at 14.5 inches, its length at 116 inches, and its weight at 3260 pounds. The nose was a heavy forging with a blunt shape for water and ground entry, and contained the internal gun barrel, tamper, and projectile.

(b)(3)

A saddle on the external top of the bomb case contained switches and electrical connections to operate the primers.[25]

Sandia had proposed that an interlaboratory gun-type weapon coordination committee be established, similar in scope and authority to the TX-5 Steering Committee. Action was taken on this suggestion in late 1950, and the first meeting of this Gun Committee, with representation from Los Alamos and Sandia, was held December 8, 1950.[26] At this time, the TX-5 Steering Committee was renamed the TX-N Steering Committee to reflect its interest in all implosion weapons, and the new Gun Committee came to be known as the TX-G Steering Committee.

The first meeting of the TX-G Committee heard a report from Los Alamos concerning progress on design of an initiator for the TX-8. The initial design had been based on the device used in the Little Boy, and was then modified as design weaknesses were uncovered by the testing program. Some idea of the problems encountered were shown by the increasing impact requirements as the design progressed. The initial

assumption had been that the highest shock encountered in ground impact would be 7500 g's. This figure had progressively increased during design and was now 100,000 to 300,000 g's.

(b)(3)

Studies were meanwhile in progress on systems for nuclear safing.

(b)(3)

In early 1951 it was decided to identify the adaptation of the TX-8 for external carriage at subsonic speeds as the TX-8' (or TX-8 Prime) program. Plans were made to make only minor changes to the TX-8 and provide early, but only partial, satisfaction of the requirements for an externally carried TX-8. It was felt that, if this program could not be accomplished within a short time, it should be canceled in favor of the TX-11 Bomb, then being designed for external carriage on high-speed aircraft.

At this time, the AD4 and the F4U5 were the only carriers specified for the TX-8'. The AD4 was selected as the test aircraft, and Sandia issued a contract through the Bureau of Aeronautics to Douglas Aircraft Company to modify this aircraft for TX-8 carriage. Douglas designed a nose cap to reduce drag and help protect the TX-8' fuzing elements.

In late October 1951, the TX-8' program was divided into two parts; the TX-8-X1 and TX-8-X2. The X1 was the basic TX-8' program; the X2 was to provide a cleaner aerodynamic design and reduce the drag caused by the saddle. Inasmuch as 20 drops had already been made with the TX-8-X1, its compatibility and reliability were felt to have been proven, and attention was concentrated on the TX-8-X2 design.[33]

The T-28 saddle functions were replaced by a small box located in the aircraft fuselage. This allowed the use of a standard two-hook bomb rack and increased the clearance between the externally carried bomb and the ground. Fairings were installed over the side fuzes to reduce drag. Fuze tapes used for safing were pulled through the nose fairing to protect them from the windstream. A quick disconnect was installed, to permit the weapon to be dropped with tapes in place, thus leaving barriers in the path between the primer and the propellant, and preventing the fuzes from firing the main propellant charge.

This new device was called the T-31, and a subcontract was issued for its development. Due to the subsequent failure of the subcontractor to achieve a satisfactory T-31, Sandia produced a design having the T-31 located inside the bomb pylon, thus making it possible to detach the arming tapes from the pylon after bomb release, and prevent aircraft damage caused by whipping of the tapes in the slipstream. This work was undertaken November 5, 1951, and satisfactory hardware was being produced 10 days later.

The Mk 8 Mod 0 weapon was initially produced in November 1951 and was stockpiled in January 1952.

(b)(1), (b)(3)

The Military Liaison Committee, in a letter dated October 20, 1952, requested that the bomb be designed to withstand storage for 6-month periods under occasional temperature extremes of -80°F to +165°F, and flight bomb-bay temperatures of -90°F. It was pointed out that external bomb carriage might experience even more rigorous conditions of -100°F during a 12-hour flight, and that the 24-hour limitation regarding weapon assembly would be operationally troublesome.[40]

Inasmuch as the propellant characteristics were specified by the Bureau of Ordnance, the problem was referred to this organization.[41] It was noted that the environmental criteria had been specified after detail design of the Mk 8 had been essentially completed, and that these criteria differed considerably from the initial Mk 8 development objectives. It was also pointed out that any project to provide a propellant with improved temperature characteristics would duplicate work being undertaken in the TX-11 program. The Bureau of Ordnance subsequently allowed relaxation of the temperature limitations to 7 days at 130°F, 60 days at 120°F, and indefinitely at 110°F.[42] On March 12, 1953, the Military Liaison Committee agreed that major redesign efforts toward relieving temperature limits be directed toward the TX-11.[43]

The possibility of water leakage into the interior of the gun nuclear system had been a matter of early concern.

(b)(1), (b)(3)

When recovered, there was only about half a cup of water in the barrel, and this leakage was not felt great. Nevertheless, the Military, in the April 16, 1952 meeting of the Sandia Weapons Development Board, requested that the possible effects of this leakage on weapon performance be studied.[38]

Consequently, drops were made on a limestone bed in southwestern New Mexico. This rock possessed extremely high compressive strengths, from 18,000 to 23,000 pounds per square inch (average concrete strengths were about 4500 psi).

(b)(1), (b)(3)

Only one weapon showed any evidence of leakage. Experiments were started, using O-rings as replacements for the cork gaskets used to seal the openings in the bomb case.

It had been decided that the TX-8-X2 changes constituted a modification to the fuze rather than the bomb. Thus the Mk 8 Bomb with Mk 8 Mod 1 Fuze, incorporating a frangible nose and T-31 fuze tape control, was released for production and entered stockpile September 1953.

The TX-G Committee, whose functions had been largely assumed by the Special Weapons Development Board, was dissolved in January 1954. The Aspen Committee, which was directing Sandia-Los Alamos activities on the TX-11 weapon, agreed to handle any residual interlaboratory matters on the Mk 8 program.

(b)(3)

This change was made in the Mk 8 Mod 2 Bomb which was stockpiled in May 1955.

Meanwhile, studies had been made of the desirability of replacing the original Abner initiator with an improved design, the Phoebe. This change, plus the O-rings for sealing the bomb case, was known as the TX-8-X3 program during development.[44] Changes to the Atomic Energy Act permitted the Military to produce and stockpile certain atomic weapons parts, and it was suggested that the Bureau of Ordnance assume control of TX-8-X3 production work.[45] This proposal was rejected by the Atomic Energy Commission, which felt that close phasing was required, due to changes to both nuclear and nonnuclear portions of the Mk 8, and that Sandia should retain production control.[46] The Mk 8 Mod 3 was stockpiled in October 1955.

By February 1957, the Mk 11 Bomb was in production and entering stockpile. A decision was made to retire the Mk 8 weapons on a one-for-one basis as Mk 11's entered War Reserve. This retirement program started May 1957 and was completed 2 months later.

Mk 8 Warhead

The first consideration of a gun-type device for use with guided missiles was in a Los Alamos meeting of early March 1950, in which various missile programs were discussed.[47] Little immediate action was taken and, during the summer of that year,

attention was concentrated on developing the Elsie as a free-fall bomb to be released from aircraft. However, September 13, 1950, Santa Fe Operations Office requested Sandia and Los Alamos to consider the application of a penetrating warhead to various guided missiles. The missiles suggested were the HERMES A-3, HERMES C-1, REGULUS, RIGEL, and TRITON.[48]

It was obvious that a gun-type warhead would be more impact-resistant than an implosion design, and the request was referred to the Bureau of Ordnance, then doing work on the Mk 8 Bomb.

(b)(1), (b)(3)

Any missile usage would involve higher impact velocities and require new tests and additional design effort.[49] The Division of Military Application then referred the project to the Sandia Weapons Development Board, requesting that any Mk 8 Warhead developed be compatible with the above five missiles.[50]

Sandia made a preliminary study and, December 20, 1950, reported to the Santa Fe Operations Office that a firm estimate of the magnitude of the program could not be made. The terminal velocities of the missiles cited had not been definitely fixed, but were believed to be significantly greater than any previously considered in atomic-bomb design. Sandia proposed that a general investigation of impact warheads be continued, in an effort to delineate the most universally useful type of warhead and to outline a development program.[51]

The Santa Fe Operations Office suggested that initial application of the penetrating warhead be made to the REGULUS missile. This missile, scheduled for production in 1953, had a comparatively low impact velocity, and it was felt that a suitable warhead might be created by relatively simple modifications of existing components.[52] Sandia reported, January 23, 1951, that the development of such a warhead appeared feasible, and that the Bureau of Ordnance had been requested to investigate the effects of impact velocities and warhead mounting methods on the penetration characteristics of the Mk 8 device.[53]

The XW-8/REGULUS was authorized for design activity by the Santa Fe Operations Office February 14, 1951.[54] It was noted that since the REGULUS would attain an

SECRET
RESTRICTED DATA

impact velocity of only Mach 1.2, there would be few shock problems, unless the weapon were employed against extremely hard targets such as igneous rock or heavy armor plate.[55]

It was determined that the fuzing accuracy for the XW-8/REGULUS could be less than for an air-burst device, since the only requirement was to initiate a pyrotechnic delay train about one minute prior to impact. Should the weapon be launched from a submarine, a simple arming system would protect the submarine against premature detonations.

The Sandia Weapons Development Board discussed the Mk 8 missile-warhead program in its April 10, 1951 meeting. It was felt that current weapon capabilities would not allow impact velocities higher than Mach 2.5 without danger of breakup of the device. Since the terminal velocity of the HERMES was estimated to be Mach 4.5, it was obvious that radical changes to either warhead or missile would have to be made if this missile were used. It was apparent that either approach would require much design investigation, and it was decided to consider only the XW-8/REGULUS.[56]

It was found that the warhead compartment of the REGULUS was long enough to hold the basic Mk 8 Bomb assembly, but that little excess clearance was available, and that access to the nose of the weapon was difficult. Additionally, the center of gravity of the missile would be about 30 inches forward of its optimum location, and it was decided to delete the afterbody of the Mk 8. Tests were started to determine the terraballistics of the Mk 8 without its afterbody, and to ascertain whether the warhead would break away from the missile on impact with various surfaces.[57]

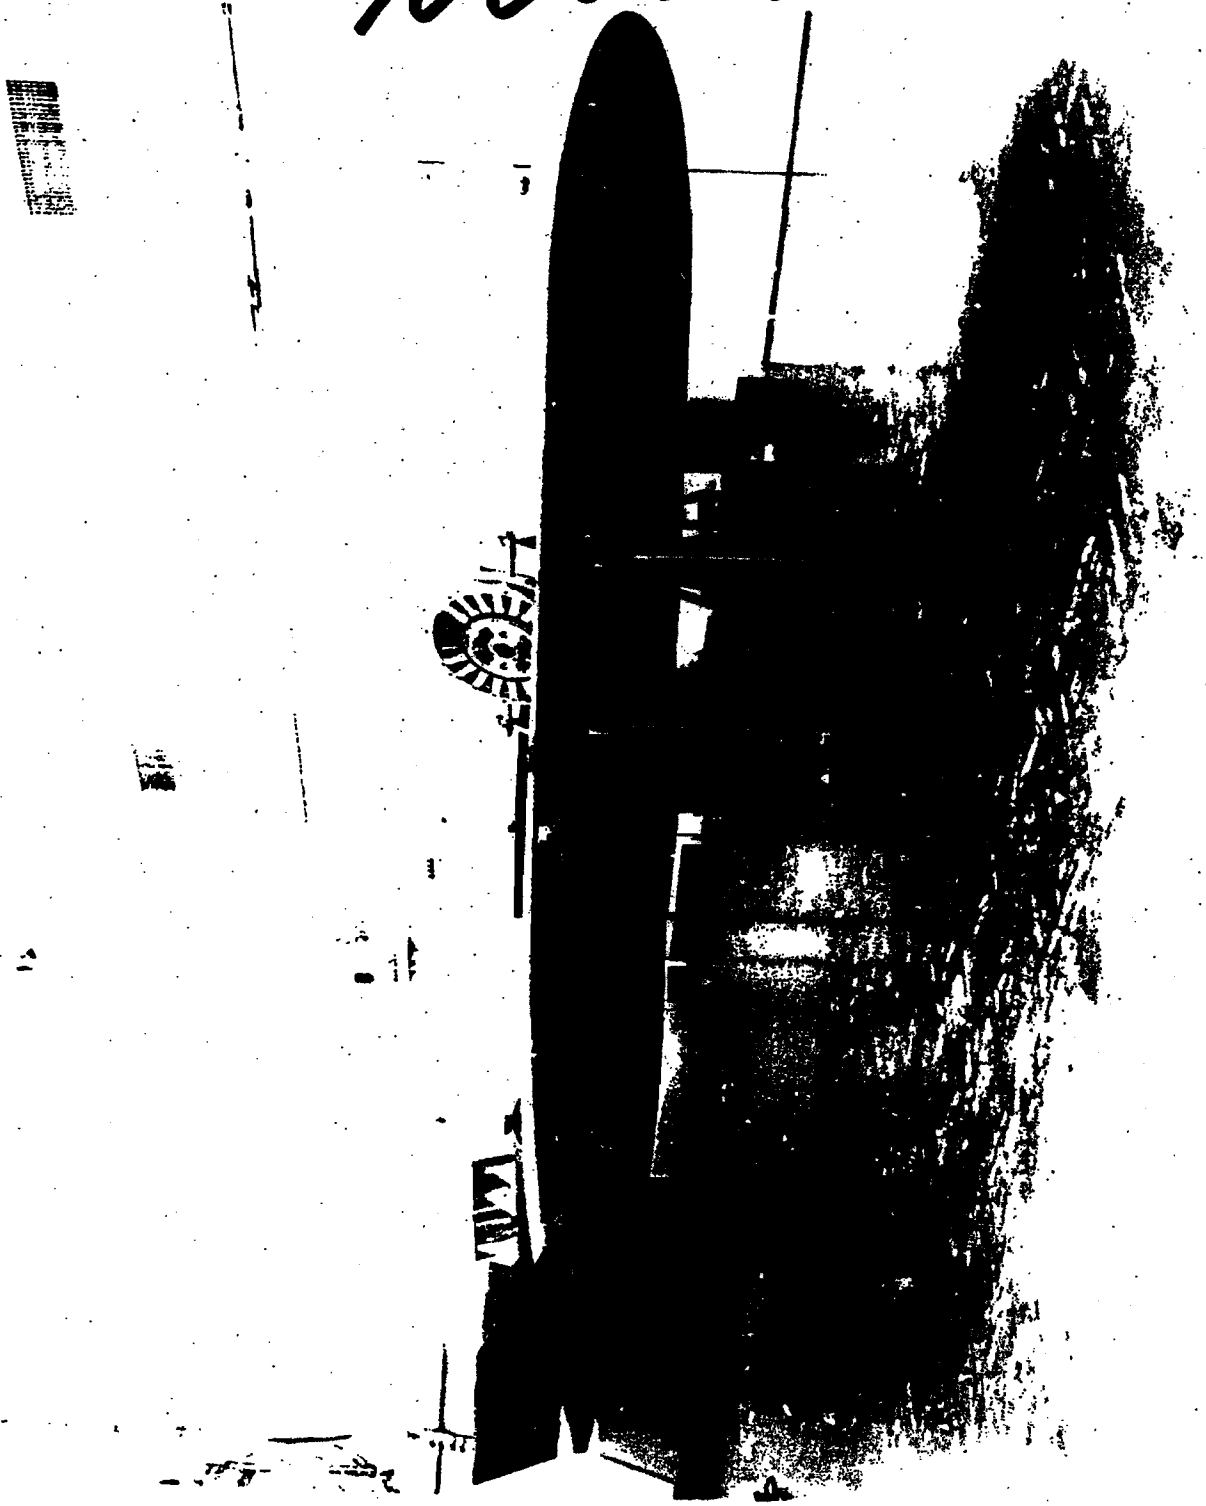
Another problem was the development of a mechanism to ignite the propellant of the internal gun device of the XW-8/REGULUS. In the drop bomb, this was accomplished by arming tapes, but the warhead application required either a device to pull the tapes at the proper point in the missile trajectory or a modification of the fuze.

yield would be the same as that of the Mk 8 Bomb. The warhead would function properly when subjected to missile impact speeds up to Mach 1.1 on water, earth, reinforced concrete and, if possible, harder targets. It would not broach or ricochet after impacts at angles between 60 and 90 degrees. The weapon would penetrate the target and detonate after coming to rest, and would be sufficiently watertight to function after water impact, followed by bottom impact.[64]

The Military Liaison Committee notified the Division of Military Application, October 3, 1952, that no requirement existed for design of penetration warheads capable of impact velocities higher than those of the REGULUS missile.[65]

Meanwhile, the Military decided that efficient use of the XW-8/REGULUS weapon required a high delivery accuracy. This was not possible with the existing missile system, and production requirements were deferred, awaiting refinement of the missile guidance system. Sandia was requested to complete its design work on the warhead, and the Navy was asked to proceed with scheduled flight tests.[66]

Successful component evaluation flights were conducted, and a successful warhead system test was held September 24, 1953. The Military Liaison Committee then suggested that, since there were few differences between the XW-8 Warhead and the extensively tested Mk 8 Bomb, further systems tests be held in abeyance.[67]



Design of the missile-warhead was completed in August 1954, and Report SC3483(TR), Status and Evaluation of the XW-8/REGULUS Warhead Installation at Design Release, was presented to the December 1, 1954 meeting of the Special Weapons Development Board.[68] The warhead was named the Mk 8 Mod 2, and production responsibility assigned to the Bureau of Ordnance.

The warhead contained three delay fuzes, two located on the side and one on the nose. (b)(3)

All requirements of the military characteristics were satisfied by the test program, although impact tests at less than 90 degrees were not conducted, and it was

not definitely determined whether the warhead would penetrate the target or break away on impact. However, Mk 8 Bomb tests had shown that satisfactory penetrations were achieved at entry angles as low as 30 degrees to the surface, and it was felt that the warhead would have similar satisfactory characteristics.

Subsequently, the possibility of developing a guidance system to effectively deliver the XW-8/REGULUS with pinpoint accuracy appeared remote. Consequently, on May 20, 1955, the Navy suspended activity in the program, together with work on the XW-11/REGULUS application.[69]

TX-10 External View

Subsequently, the Division of Military Application proposed that a lightweight, air-burst, gun-type missile warhead be developed,[74] and this suggestion received the backing of the Military Liaison Committee July 6, 1950.[75] It was proposed that Army Ordnance, then involved with the Mk 9 Shell, be requested to assist in design and development.[76]

Meanwhile, the lightweight, air-burst, gun-type bomb project had not been entirely forgotten, and the Military Liaison Committee, in a letter dated August 9, 1950, stated that the Joint Chiefs of Staff had established a requirement for the development of air-burst bombs sufficiently light in weight and small in cross section to be carried by high-speed tactical airplanes of the Air Force and Navy. It was felt that these bombs could be based on either implosion- or gun-type nuclear devices, and formal requests were made for both types.[77]

The subject was discussed in the August 16, 1950 meeting of the Sandia Weapons Development Board, with the Board agreeing to assume cognizance of the project. Two problems were immediately apparent: The development of a flexible fuzing system capable of attacking various tactical targets, and a weapon resistant to temperatures as low as -100°F.[78]

Sandia had meanwhile made a study of a lightweight bomb design and reported to AEC-Sandia August 17, 1950, that this could be produced by mid-1952. It was suggested that North American Aviation, Inc., be assigned the task of developing and manufacturing the outer case, internal support structures, and parts of the carrying pylon. Sandia would develop a fuzing and firing system, conduct drop tests, provide test and handling equipment, and act as project coordinator.[79]

On the same date, the Division of Military Application forwarded military characteristics for the above bomb. These required that the bomb be capable of tactical use by fighter, light bombardment, and attack (dive bomber) aircraft. The primary requirement was for external carriage, with alternate internal carriage being desired.

(b)(1), (b)(3)

The TX-G or Gun Committee agreed to accept interlaboratory responsibility for the TX-10.[26] The program was subjected to an intensive review in a Committee meeting of December 14, 1950, with the TX-10 being compared with the TX-7, an implosion design that had been pushed rapidly and which was now scheduled to enter stockpile earlier than the TX-10. It was felt by some conferees that the basic need for the TX-10 was eliminated by the advent of the TX-7. This latter weapon was larger than the proposed diameter of the TX-10 (27 inches versus 17 inches), but there appeared to be a sufficient variety of airplanes that could carry the TX-7.

(b)(1), (b)(3)

The problem was referred to the Sandia Weapons Development Board and discussed in a meeting December 20, 1950, with the Board being furnished copies of Sandia Report SC-1684(TR), A Critical Comparison Between the TX-7 and TX-10 Programs. This report noted that design was in work on a follow-on (and smaller) implosion device for the TX-7 (to be called the TX-12). The TX-12 would be less costly from the nuclear standpoint, would offer greater chances of increasing nuclear efficiency, and could be developed in about the same time scales. It was pointed out that work on the TX-10 would subtract effort from the TX-12, and that tactical use of the TX-10 (if manufactured in large numbers) would require major realignment of component production.

The Board noted that the TX-10 diameter would probably be smaller than the TX-7 or TX-12, but stated that further reductions in implosion-weapon diameter could be expected, as much nuclear design effort was currently being placed on implosion design improvements. After extensive discussion, the Board recommended that the TX-10 development be dropped in favor of the TX-12.[89]

The Division of Military Application wrote to Santa Fe Operations Office January 3, 1951, making reference to the above meeting. There were hopes that an interim TX-10 could be made available earlier than the TX-12, and it was suggested that the requirement for nuclear safing be eliminated and an external shape suitable for subsonic (but not necessarily supersonic) carriage be provided.[90]

The design status of the TX-10 was reviewed in the April 10, 1951 meeting of the Sandia Weapons Development Board. The bomb would be at least 17 inches in diameter and 2000 pounds in weight.

(b)(3), (b)(1)

The Board noted that the diameter and weight of the TX-10 exceeded the military characteristics, and that major reductions in these items could not be expected until the nuclear gun design was revised by Los Alamos.

(b)(3)

The project thus reverted to fundamental study of the problems of providing low burst heights, miniaturization, supersonic aerodynamics, and nuclear design improvements. Subsequently, the Military Liaison Committee canceled the TX-10 Bomb program May 7, 1952, noting that the Joint Chiefs of Staff had stated that a military requirement for the weapon no longer existed.

(b)(3)

SECRET
RESTRICTED DATA

Mk 11 Weapon

The Mk 11 Bomb, a gun-type penetrating weapon to be externally carried on high-speed aircraft, had its early beginnings when the gun-type device was considered for guided-missile application in March 1950. In this usage nuclear safing would be required to protect the missile launching site, and it would be necessary for the warhead to survive high impact velocities.[47]

Subsequently, the Division of Military Application expressed interest in a gun-type bomb that could be nuclearly safed and externally carried on high-speed aircraft.[99] The external shape of the Mk 8 did not lend itself to such carriage (due chiefly to its blunt nose), and it was felt that any modification of the nose shape would be complicated by the existence of the nose fuze. A nose redesign would require a lengthy effort, and it was suggested that a development program be authorized for a Mk II Elsie for such usage.[100]

The Military Liaison Committee released a set of desired military and technical characteristics for impact, delayed-action atomic bombs April 17, 1950. These characteristics described a bomb which could be nuclearly safed during aircraft carriage and that would be suitable for release at speeds up to Mach 1.2.[54] Subsequently, July 31, 1950, the Division of Military Application requested the Bureau of Ordnance to design a Mk 8-type weapon meeting these characteristics, and offered Sandia assistance in the task of fitting the design to appropriate carrying aircraft.[101] This proposal was accepted by the Bureau of Ordnance,[102] and nomenclature of TX-11 was assigned to the project November 29, 1950.[103]

There were three main gun-weapon problems being studied at this time: The ballistics problem relating to external carriage and release at high speeds; the nuclear safing problem, which concerned missiles as well as bombs; and the problem of increasing the resistance of the weapon to impacts on hard targets, such as reinforced concrete, rock and armor plate.

The Naval Ordnance Laboratory started to design the TX-11 fuzing system. It was felt that feasibility and preliminary design studies to establish tentative characteristics could be completed by January 1, 1952; and that detailed design

toss, glide and dive bombing. It would be capable of carriage and release at speeds up to Mach 1.4 and altitudes of 50,000 feet. It would be able to function satisfactorily after impacts on water, soil, reinforced concrete, and--to the extent practicable--harder targets.

The Board noted that the characteristics required external carriage at both subsonic and supersonic speeds, but a shape designed for one of these velocities would not be optimum for the other. It was felt that the design should be based on the assumption that the least drag during the major portion of the flight was desirable. Inasmuch as jet fighters en route to a target cruised at subsonic speeds, the bomb shape should be designed to meet this requirement.

The desire that the weapon be capable of penetration into hard rock was of concern. It was difficult to suitably define "hard rock," and there was felt to be a low incidence of this type of terrain near any probable targets. The scheduled design-release date was established as October 1953, with the bomb to enter stockpile in January 1955.[34]

The Bureau of Ordnance had been conducting tests of a soft-steel nose cap which, it was hoped, would crush and absorb the shock of weapon impact. These tests were not encouraging, and it was eventually decided to provide a Fiberglas nose cap. When the bomb was to be carried in an internal bomb bay, this nose cap could be removed.

Wind-tunnel tests had meanwhile narrowed the choice of weapon length to two possibilities; 146 and 169 inches. The Bureau of Ordnance recommended that the shorter figure be selected: It caused less drag at subsonic speed, it was compatible with all aircraft being considered for carriage of the bomb, and it could be carried internally in all aircraft except the B-50 without removing the nose cap.[109]

Full-scale drops at Inyokern produced excellent results.

(b)(1), (b)(3)

No detonation of the high explosive occurred during any of the impacts. Tests of 6-1/4-inch-diameter scale models against reinforced concrete 10 feet thick demonstrated that impact velocities between 2000 and 2200 feet per second could be

absorbed.[110] As a result of these tests, the length of the TX-11 was frozen at 146 inches on June 30, 1952, and the fin size was established at two bomb diameters, or 28 inches.[111]

Meanwhile, work had been undertaken on the design of a nuclear safing system,

(b)(3)

The fuzes were mechanically armed and were of a pyrotechnic design similar to those used in the Mk 8.

Glossary of Terms

Ad Hoc Working Group -- A group established by the Guided Missiles Committee to oversee the design of one particular missile-warhead installation.

Armed Forces Special Weapons Project -- An interdepartmental agency formed to handle military functions related to atomic weapons.

(b)(1), (b)(3)

Contact Fuze -- A fuze that detonates the weapon by contact with the ground or target.

Crossroads -- Full-scale tests of Mk III Bombs, held at the Pacific Proving Grounds. The Bikini Baker shot was held July 25, 1946. Much effects data were gained, and the shot was so destructive that a scheduled deep underwater burst was canceled.

Division of Military Application -- An AEC office that functions as liaison between the Military and weapons designers and producers.

Drag -- Resistance created by the passage of a shape through the air.

Field Command -- The local office of the Armed Forces Special Weapons Project, located on Sandia Base, Albuquerque, New Mexico.

Joint Research and Development Board -- A Board established in mid-1946 as a postwar replacement for the Office of Scientific Research and Development. Its purpose was to suggest lines of research and development on military weapons and equipment.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Little Boy -- Code name for the gun-type weapon dropped on Hiroshima, Japan, August 6, 1945, during World War II. Originally called the Thin Man in reference to its long thin shape. The Thin Man was to use plutonium-239 as its nuclear material. Early samples of this isotope revealed that it contained small amounts of plutonium-240 which had a high preinitiation rate. A decision was then made to use uranium-235, allowing the length of the weapon to be radically reduced (due to the lower speed of assembly of the critical material). This change in outer shape was given the code name of Little Boy.

Los Alamos Scientific Laboratory -- A nuclear design organization located at Los Alamos, New Mexico. Called the Los Alamos Laboratory during World War II.

Mach -- A measure of speed. Mach 1.0 is the speed of sound, or 738 miles per hour at sea level.

Manhattan Engineer District -- A District of the Army Engineers established in August 1942 to provide the facilities that would be needed for design and construction of the atomic bomb.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

A En r v t Man n t l E

s A i ro e o o y s I

Naval Ordnance Laboratory -- A portion of the Bureau of Ordnance devoted to design and test of Naval ordnance.

Neutron -- An uncharged particle of slightly greater mass than the proton.

Operation Crossroads -- See Crossroads.

Pitch -- Motion of the bomb as it falls through the air, such that the nose and tail alternately rise and fall.

Proton -- The nucleus of the atom of the light isotope of hydrogen. It has a unit positive charge of electricity.

Prototype -- An early weapon type, generally hand-produced before a production run.

Pylon -- A strut to hold bomb in position below an airplane wing.

Pyrotechnic Fuze -- A fuze that operates by burning or detonation of a small charge of explosive.

Radar -- Named for Radio Detecting and Ranging. Radars emit a pulse of high-frequency energy and measure the time lapse from that transmission to receipt of a reflected electrical "echo" from an object. This time measurement determines the distance of the object from the transmitting antenna of the radar.

Ricochet -- A glancing rebound of a missile when it strikes a target.

Safing -- Putting a weapon in condition such that it cannot fire.

Salton Sea Test Base -- Located on the site of a Naval Auxiliary Air Station on the shores of Salton Sea, California. One of the early sites for ballistic tests of atomic bombs.

Sandia Research and Development Board -- A joint Sandia-Military board formed March 2, 1948, at Sandia Base to provide local guidance on weapons design.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent of uranium-238; the rest is uranium-235.

Z Division -- A division of the Los Alamos Scientific Laboratory, elements of which moved to Sandia Base and became the nucleus of Sandia Laboratory and Corporation.

Mk 8 Cross Section

12/8/50	TX-G Steering Committee appointed and holds initial meeting.
1/26/51	
	(b)(3)
3/15/51	
Early 1951	Externally carried TX-8 Bomb assigned nomenclature of TX-8 Prime.
10/51	TX-8 Prime program divided into two parts: TX-8-X1 (to cover carriage at subsonic speeds) and TX-8-X2 (a program to reduce drag in high-speed carriage).
11/51	Mk 8 Mod 0 achieves production.
1/52	Mk 8 Mod 0 enters stockpile.
4/1/52	
	(b)(3)
9/53	Mk 8 Bomb with Mk 8 Mod 1 Fuze (TX-8-X2) enters stockpile.
11/55	Mk 8 Mod 3 Bomb enters stockpile.
5/57	Mk 8 Bombs retired as Mk 11 enters stockpile.

Mk 8 Warhead

3/50	Gun-type warheads considered for missile application.
9/13/50	Santa Fe Operations Office requests that penetrating warheads be applied to guided missiles.
2/14/51	Santa Fe Operations Office authorizes design of XW-8/REGULUS.
1/18/52	XW-5/REGULUS program assigned priority over XW-8/REGULUS.
8/21/52	Field Command forwards proposed military characteristics for XW-8/REGULUS to Sandia.
9/24/53	Successful XW-8/REGULUS system test held.

8/54 Design of XW-8/REGULUS completed.

5/20/55 Program activity suspended.

TX-10 Weapon

5/6/48 Sandia Research and Development Board assigns priorities to weapon design projects.

1/21/49 Division of Military Application requests Bureau of Ordnance to study possible adaptation of Mk 8 as a light air-burst weapon.

4/22/49 Military Liaison Committee requests that study be restricted to a preliminary investigation.

3/8/50 Guided-missile symposium at Sandia Base proposes use of a light-weight gun-type device as a missile warhead.

7/6/50 Military Liaison Committee releases formal requirement for an air-burst, gun-type warhead.

8/9/50 Military Liaison Committee establishes formal requirement for a lightweight air-turst bomb.

8/17/50 Division of Military Application forwards characteristics for lightweight air-burst bombs.

9/6/50 Bureau of Ordnance, in reply to January 21, 1949 request of the Division of Military Application, offers to adapt the Mk 8 as a lightweight air-burst bomb.

10/3/50 Division of Military Application notifies Bureau of Ordnance that Sandia will develop the lightweight air-burst bomb.

10/18/50 Sandia Weapons Development Board discusses bomb and warhead applications. Santa Fe Operations Office subsequently authorizes deletion of warhead requirement. Bomb officially designated the TX-10.

(b)(3)

History of Gun-Type Bombs and Warheads

Mk 8 Bomb

The gun method of assembling nuclear material, used in the wartime Little Boy design, was the first atomic weapon system to be devised, predating the establishment of the Los Alamos Laboratory. The method was nuclearly inefficient and was largely ignored for a time after the end of World War II, while interest centered on implosion techniques.

(b)(1), (b)(3)

At this time, the Los Alamos Scientific Laboratory was fully occupied in the above-mentioned study of improvements in implosion devices, and suggested that the task of developing a water-penetrating weapon (which probably would use gun techniques) could best be accomplished by a military group. No immediate action was taken on this suggestion, but the subject was briefly examined by the Z Division of Los Alamos in late 1946 and early 1947.

(b)(1), (b)(3)

The topic was subsequently discussed in a meeting of the Weapons Subcommittee of the AEC General Advisory Committee, and a decision made May 15, 1947 that consideration of a penetrating weapon be postponed.[4]

Meanwhile, however, the Military Liaison Committee had been discussing the general subject of subsurface atomic weapons. At the instigation of the Navy member, Rear Admiral William S. Parsons (who had armed the wartime gun-type Little Boy for

its historic drop on Hiroshima), Section ReM of the Navy's Bureau of Ordnance, prepared preliminary sketches of a penetrating gun device.

At about the same time, other groups were considering the same subject. The Joint Research and Development Board had established a Committee on Atomic Energy, and the subject of penetrating weapons was discussed in the October 2, 1947 meeting of this Committee. It was urged that serious consideration be given to the development of a gun-type device suitable for penetration use. Since the AEC weapon laboratories were already fully occupied with other high-priority work, the Committee recommended that the facilities of the Bureau of Ordnance be used.[5]

The Division of Military Application had also been considering the advisability of invoking the assistance of the military services in the development of penetrating weapons. Los Alamos had noted that gun systems were inherently inefficient, and expressed an opinion that the weapons laboratories should continue to concentrate on design of implosion devices.[6] Thus the Military Liaison Committee was requested to assign mechanical design of a gun-type penetration weapon to the Bureau of Ordnance.[7]

These several requests, all in the same vein, were presented for consideration to the Military Liaison Committee which, April 9, 1948, requested the Atomic Energy Commission to undertake development of a penetrating-type weapon, using the facilities of the Bureau of Ordnance.[8] This request was formally presented to the Bureau April 27, 1948, and accepted.[9] A code name of "Minnie" was initially assigned to the project, but was later found to have been used for a Bureau of Ships propulsion project and, in mid-July 1948, the name was changed to "LC" (a follow-on term to "LB," for the Little Boy), and which came to be commonly written as "Elsie."[10] That the Elsie program was considered a matter of some interest to the Military was indicated in a May 6, 1948 meeting of the Sandia Research and Development Board in which the project was assigned top priority, second only to the schedule for getting the Mk 4 Bomb into full-scale production.

The Bureau of Ordnance issued detailed work assignments. The Naval Ordnance Laboratory would be responsible for developing suitable pyrotechnic delay fuzes.

The Naval Ordnance Test Station would study external ballistics and design the tail. The Naval Powder Factory would investigate powder development. The Naval Ordnance Plant would handle much of the manufacturing and testing program, and when this location was subsequently closed, the work would be transferred to the Naval Proving Grounds and the Naval Gun Factory. Section ReM of the Bureau of Ordnance would provide overall design controls, including the task of guaranteeing survival of the nuclear assembly under impact conditions.

The development program would proceed in three overlapping phases. Feasibility and preliminary design studies would outline the most promising general design characteristics of the weapon, and these were scheduled for completion January 1, 1949. The second phase, covering experimental development and testing of prototype weapon design, would be completed a year later. The third phase, manufacture of prototype weapons, would be finished in another year, or January 1, 1951.

(b)(3)

The studies advanced rapidly and, by September 3, 1948, the Bureau of Ordnance could report that the design appeared feasible and that a weapon could probably be devised that would function satisfactorily after impact on water, and possibly after impact on hard surfaces which the weapon might encounter beneath the surface of the water.[11] It was initially felt that the fuze should be actuated at impact and have a delay of 1 to 2 minutes before bomb detonation, but it was later decided that a more reliable bomb would be created if the fuze action were initiated at time of release of the bomb from the carrying aircraft.

The diameter of the bomb would be about 14 inches and the weight would be about 3000 pounds, as compared to 28 inches and 8900 pounds for the Little Boy. These reductions were due to the more compact nuclear assembly and a decrease in the thickness of the bomb case. The shape would be roughly cylindrical, with a flat nose for good penetration characteristics, and the bomb would attain a maximum impact velocity of 1500 feet per second. The minimum release altitude would be 500 feet, to give the bomb enough time during its fall to assume proper entry attitude, and there would be no restriction on maximum release altitude. It was felt that three separate and independent fuzes should be used, to provide adequate relisbility. A meeting was held October 25 and 26, 1948, with Los Alamos assuming the task of developing impact-resistant initiators.[12]

An extensive series of tests was performed. The first group included 174 half-scale bombs of 6.25-inch diameter. These were fabricated in 49 different configurations, and were impacted against targets of steel and concrete at different angles, striking velocities, and missile temperatures ranging from -65°F to +165°F.

(b)(3)

Following the above, some 38 full-scale impact tests were conducted, to confirm the half-scale results. Interior ballistic tests were performed, to check the burning rate of various propellants and the behavior of the missile in the gun barrel. As fuze components became available, they were subjected to the shock produced by firing from a 14.25-inch-diameter railway gun.

Two series of wind-tunnel tests were held, one at the University of Minnesota to obtain aerodynamic coefficients of various tail configurations, and the other at the California Institute of Technology Cooperative Wind Tunnel to evaluate aerodynamic characteristics of five basic designs.

directive was issued August 30, 1950, accompanied by a request that the facilities of the Bureau of Ordnance be used to the fullest extent possible.[17] At this time, the Elsie was assigned nomenclature of TX-8.[18]

An intensive study had been undertaken of changes required to allow external carriage of the TX-8. There were several reasons why these changes were necessary. For one, the fuze system had been designed to operate under protected bomb-bay conditions. For another, the shape of the TX-8, with its blunt nose, caused excessive drag, especially at high speeds.

(b)(3)

It was obvious that this would require considerable study, and it was suggested that the Bureau of Ordnance establish a parallel program for the development of a Mk II Elsie suitable for either internal or external suspension, while work continued on an internally carried TX-8.[19]

The Bureau made a survey and reported that the existing shape of the TX-8 was adequate for subsonic external carriage if some minor changes were made to the tail design,[20] and the shape could be carried in the space available under the centerline of the F4U, AD and A2D airplanes. It was noted that development of a shape for external carriage at supersonic velocities would require additional study and development, and this effort would be of interest in connection with a recent proposal that an XW-8 Warhead be fitted to a guided missile. Subsequently, October 3, 1950, the Division of Military Application authorized development of an externally carried TX-8 with subsonic aircraft and development of a new bomb (the TX-11) for high-speed external carriage.[21]

Meanwhile, the Armed Forces Special Weapons Project had been drawing up a paper specifying the desired military and technical characteristics of penetrating-type weapons.

(b)(1), (b)(3)

This paper was circulated for comment to Sandia and Los Alamos as well as the Military, and was subjected to a critical review.[23] The formal issue of the characteristics on November 10, 1950, however, retained the release speed requirement and noted that the bomb should function reliably when released at any altitude up to 50,000 feet and survive impacts on water, reinforced concrete, and--hopefully--thin steel plate.

(b)(3)

The November 22, 1950 meeting of the Sandia Weapons Development Board reviewed the overall gun-type weapons program, which now included the TX-9, TX-10, and TX-11, in addition to the TX-8. It was noted that the TX-8 was composed of three main parts: The nose, the tail, and the clamping ring which joined them. The bomb diameter had been fixed at 14.5 inches, its length at 116 inches, and its weight at 3260 pounds. The nose was a heavy forging with a blunt shape for water and ground entry, and contained the internal gun barrel, tamper, and projectile.

(b)(3)

A saddle on the external top of the bomb case contained switches and electrical connections to operate the primers.[25]

Sandia had proposed that an interlaboratory gun-type weapon coordination committee be established, similar in scope and authority to the TX-5 Steering Committee. Action was taken on this suggestion in late 1950, and the first meeting of this Gun Committee, with representation from Los Alamos and Sandia, was held December 8, 1950.[26] At this time, the TX-5 Steering Committee was renamed the TX-N Steering Committee to reflect its interest in all implosion weapons, and the new Gun Committee came to be known as the TX-G Steering Committee.

The first meeting of the TX-G Committee heard a report from Los Alamos concerning progress on design of an initiator for the TX-8. The initial design had been based on the device used in the Little Boy, and was then modified as design weaknesses were uncovered by the testing program. Some idea of the problems encountered were shown by the increasing impact requirements as the design progressed. The initial

assumption had been that the highest shock encountered in ground impact would be 7500 g's. This figure had progressively increased during design and was now 100,000 to 300,000 g's.

(b)(3)

Studies were meanwhile in progress on systems for nuclear safing.

(b)(3)

In early 1951 it was decided to identify the adaptation of the TX-8 for external carriage at subsonic speeds as the TX-8' (or TX-8 Prime) program. Plans were made to make only minor changes to the TX-8 and provide early, but only partial, satisfaction of the requirements for an externally carried TX-8. It was felt that, if this program could not be accomplished within a short time, it should be canceled in favor of the TX-11 Bomb, then being designed for external carriage on high-speed aircraft.

At this time, the AD4 and the F4U5 were the only carriers specified for the TX-8'. The AD4 was selected as the test aircraft, and Sandia issued a contract through the Bureau of Aeronautics to Douglas Aircraft Company to modify this aircraft for TX-8 carriage. Douglas designed a nose cap to reduce drag and help protect the TX-8' fuzing elements.

In late October 1951, the TX-8' program was divided into two parts; the TX-8-X1 and TX-8-X2. The X1 was the basic TX-8' program; the X2 was to provide a cleaner aerodynamic design and reduce the drag caused by the saddle. Inasmuch as 20 drops had already been made with the TX-8-X1, its compatibility and reliability were felt to have been proven, and attention was concentrated on the TX-8-X2 design.[33]

The T-28 saddle functions were replaced by a small box located in the aircraft fuselage. This allowed the use of a standard two-hook bomb rack and increased the clearance between the externally carried bomb and the ground. Fairings were installed over the side fuzes to reduce drag. Fuze tapes used for safing were pulled through the nose fairing to protect them from the windstream. A quick disconnect was installed, to permit the weapon to be dropped with tapes in place, thus leaving barriers in the path between the primer and the propellant, and preventing the fuzes from firing the main propellant charge.

This new device was called the T-31, and a subcontract was issued for its development. Due to the subsequent failure of the subcontractor to achieve a satisfactory T-31, Sandia produced a design having the T-31 located inside the bomb pylon, thus making it possible to detach the arming tapes from the pylon after bomb release, and prevent aircraft damage caused by whipping of the tapes in the slipstream. This work was undertaken November 5, 1951, and satisfactory hardware was being produced 10 days later.

The Mk 8 Mod 0 weapon was initially produced in November 1951 and was stockpiled in January 1952.

(b)(1), (b)(3)

The Military Liaison Committee, in a letter dated October 20, 1952, requested that the bomb be designed to withstand storage for 6-month periods under occasional temperature extremes of -80°F to +165°F, and flight bomb-bay temperatures of -90°F. It was pointed out that external bomb carriage might experience even more rigorous conditions of -100°F during a 12-hour flight, and that the 24-hour limitation regarding weapon assembly would be operationally troublesome.[40]

Inasmuch as the propellant characteristics were specified by the Bureau of Ordnance, the problem was referred to this organization.[41] It was noted that the environmental criteria had been specified after detail design of the Mk 8 had been essentially completed, and that these criteria differed considerably from the initial Mk 8 development objectives. It was also pointed out that any project to provide a propellant with improved temperature characteristics would duplicate work being undertaken in the TX-11 program. The Bureau of Ordnance subsequently allowed relaxation of the temperature limitations to 7 days at 130°F, 60 days at 120°F, and indefinitely at 110°F.[42] On March 12, 1953, the Military Liaison Committee agreed that major redesign efforts toward relieving temperature limits be directed toward the TX-11.[43]

The possibility of water leakage into the interior of the gun nuclear system had been a matter of early concern.

(b)(1), (b)(3)

When recovered, there was only about half a cup of water in the barrel, and this leakage was not felt great. Nevertheless, the Military, in the April 16, 1952 meeting of the Sandia Weapons Development Board, requested that the possible effects of this leakage on weapon performance be studied.[38]

Consequently, drops were made on a limestone bed in southwestern New Mexico. This rock possessed extremely high compressive strengths, from 18,000 to 23,000 pounds per square inch (average concrete strengths were about 4500 psi).

(b)(1), (b)(3)

Only one weapon showed any evidence of leakage. Experiments were started, using O-rings as replacements for the cork gaskets used to seal the openings in the bomb case.

It had been decided that the TX-8-X2 changes constituted a modification to the fuze rather than the bomb. Thus the Mk 8 Bomb with Mk 8 Mod 1 Fuze, incorporating a frangible nose and T-31 fuze tape control, was released for production and entered stockpile September 1953.

The TX-G Committee, whose functions had been largely assumed by the Special Weapons Development Board, was dissolved in January 1954. The Aspen Committee, which was directing Sandia-Los Alamos activities on the TX-11 weapon, agreed to handle any residual interlaboratory matters on the Mk 8 program.

(b)(3)

This change was made in the Mk 8 Mod 2 Bomb which was stockpiled in May 1955.

Meanwhile, studies had been made of the desirability of replacing the original Abner initiator with an improved design, the Phoebe. This change, plus the O-rings for sealing the bomb case, was known as the TX-8-X3 program during development.[44] Changes to the Atomic Energy Act permitted the Military to produce and stockpile certain atomic weapons parts, and it was suggested that the Bureau of Ordnance assume control of TX-8-X3 production work.[45] This proposal was rejected by the Atomic Energy Commission, which felt that close phasing was required, due to changes to both nuclear and nonnuclear portions of the Mk 8, and that Sandia should retain production control.[46] The Mk 8 Mod 3 was stockpiled in October 1955.

By February 1957, the Mk 11 Bomb was in production and entering stockpile. A decision was made to retire the Mk 8 weapons on a one-for-one basis as Mk 11's entered War Reserve. This retirement program started May 1957 and was completed 2 months later.

Mk 8 Warhead

The first consideration of a gun-type device for use with guided missiles was in a Los Alamos meeting of early March 1950, in which various missile programs were discussed.[47] Little immediate action was taken and, during the summer of that year,

attention was concentrated on developing the Elsie as a free-fall bomb to be released from aircraft. However, September 13, 1950, Santa Fe Operations Office requested Sandia and Los Alamos to consider the application of a penetrating warhead to various guided missiles. The missiles suggested were the HERMES A-3, HERMES C-1, REGULUS, RIGEL, and TRITON.[48]

It was obvious that a gun-type warhead would be more impact-resistant than an implosion design, and the request was referred to the Bureau of Ordnance, then doing work on the Mk 8 Bomb.

(b)(1), (b)(3)

Any missile usage would involve higher impact velocities and require new tests and additional design effort.[49] The Division of Military Application then referred the project to the Sandia Weapons Development Board, requesting that any Mk 8 Warhead developed be compatible with the above five missiles.[50]

Sandia made a preliminary study and, December 20, 1950, reported to the Santa Fe Operations Office that a firm estimate of the magnitude of the program could not be made. The terminal velocities of the missiles cited had not been definitely fixed, but were believed to be significantly greater than any previously considered in atomic-bomb design. Sandia proposed that a general investigation of impact warheads be continued, in an effort to delineate the most universally useful type of warhead and to outline a development program.[51]

The Santa Fe Operations Office suggested that initial application of the penetrating warhead be made to the REGULUS missile. This missile, scheduled for production in 1953, had a comparatively low impact velocity, and it was felt that a suitable warhead might be created by relatively simple modifications of existing components.[52] Sandia reported, January 23, 1951, that the development of such a warhead appeared feasible, and that the Bureau of Ordnance had been requested to investigate the effects of impact velocities and warhead mounting methods on the penetration characteristics of the Mk 8 device.[53]

The XW-8/REGULUS was authorized for design activity by the Santa Fe Operations Office February 14, 1951.[54] It was noted that since the REGULUS would attain an

SECRET
RESTRICTED DATA

impact velocity of only Mach 1.2, there would be few shock problems, unless the weapon were employed against extremely hard targets such as igneous rock or heavy armor plate.[55]

It was determined that the fuzing accuracy for the XW-8/REGULUS could be less than for an air-burst device, since the only requirement was to initiate a pyrotechnic delay train about one minute prior to impact. Should the weapon be launched from a submarine, a simple arming system would protect the submarine against premature detonations.

The Sandia Weapons Development Board discussed the Mk 8 missile-warhead program in its April 10, 1951 meeting. It was felt that current weapon capabilities would not allow impact velocities higher than Mach 2.5 without danger of breakup of the device. Since the terminal velocity of the HERMES was estimated to be Mach 4.5, it was obvious that radical changes to either warhead or missile would have to be made if this missile were used. It was apparent that either approach would require much design investigation, and it was decided to consider only the XW-8/REGULUS.[56]

It was found that the warhead compartment of the REGULUS was long enough to hold the basic Mk 8 Bomb assembly, but that little excess clearance was available, and that access to the nose of the weapon was difficult. Additionally, the center of gravity of the missile would be about 30 inches forward of its optimum location, and it was decided to delete the afterbody of the Mk 8. Tests were started to determine the terraballistics of the Mk 8 without its afterbody, and to ascertain whether the warhead would break away from the missile on impact with various surfaces.[57]

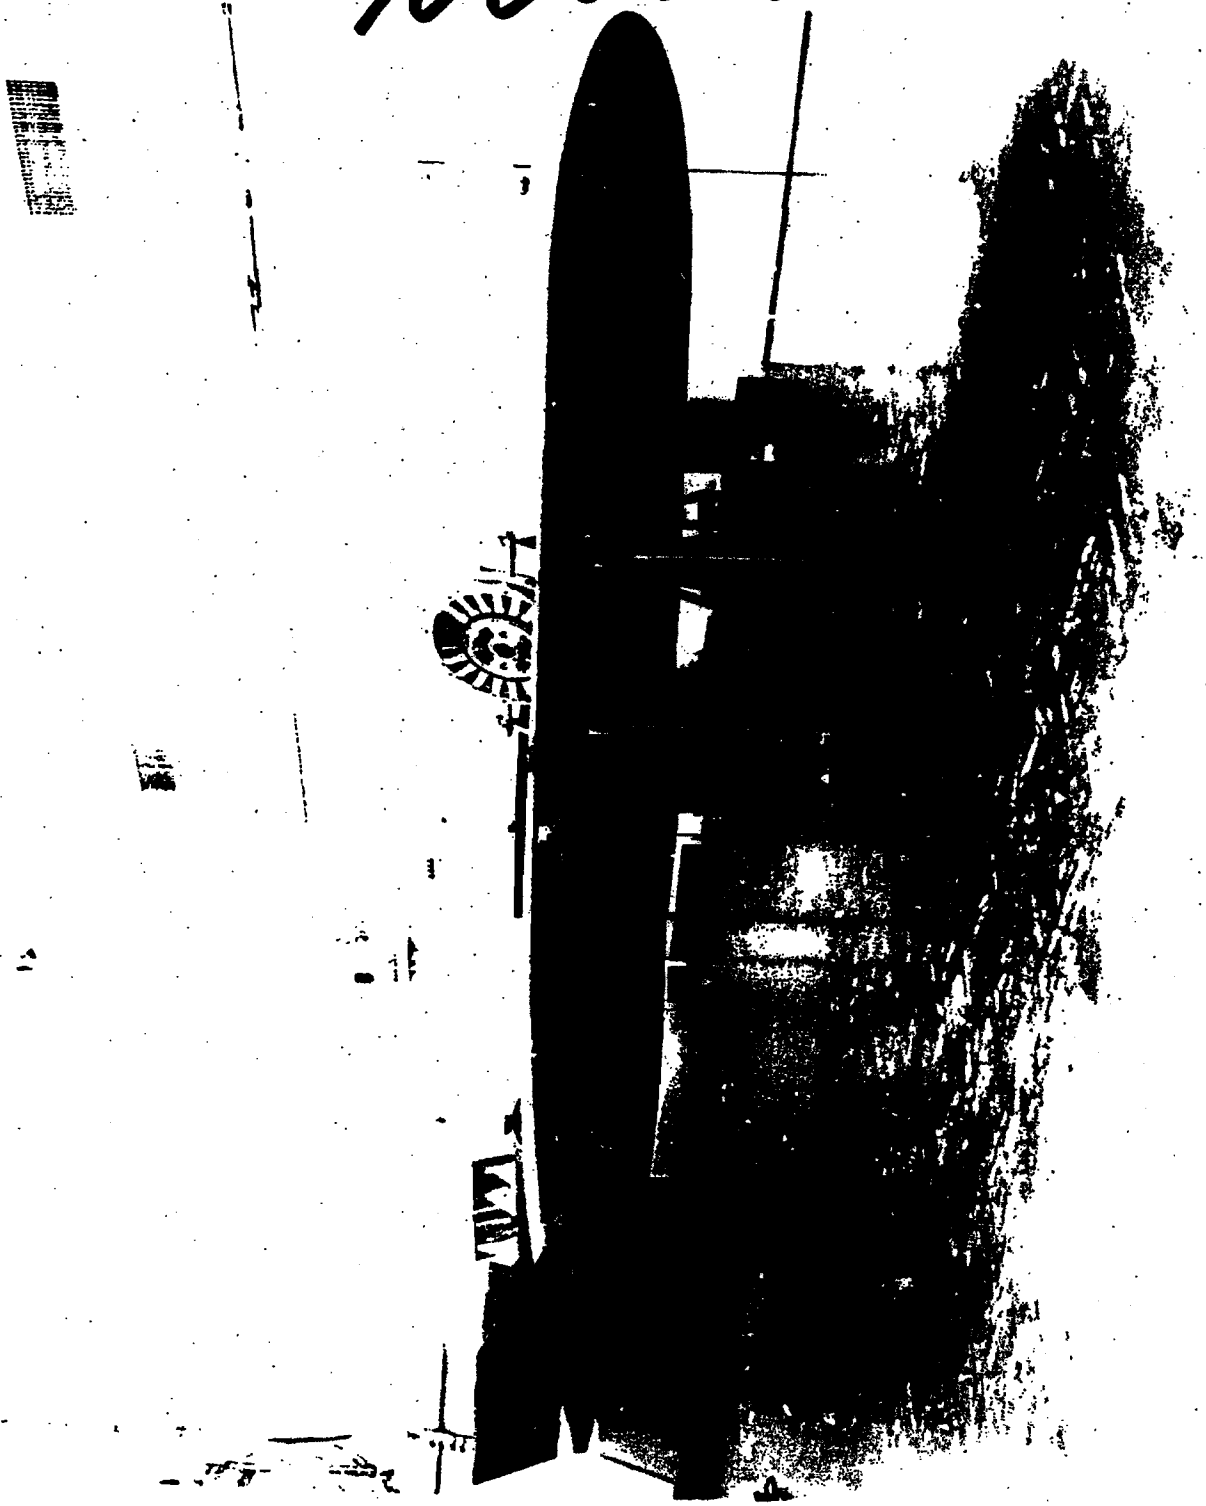
Another problem was the development of a mechanism to ignite the propellant of the internal gun device of the XW-8/REGULUS. In the drop bomb, this was accomplished by arming tapes, but the warhead application required either a device to pull the tapes at the proper point in the missile trajectory or a modification of the fuze.

yield would be the same as that of the Mk 8 Bomb. The warhead would function properly when subjected to missile impact speeds up to Mach 1.1 on water, earth, reinforced concrete and, if possible, harder targets. It would not broach or ricochet after impacts at angles between 60 and 90 degrees. The weapon would penetrate the target and detonate after coming to rest, and would be sufficiently watertight to function after water impact, followed by bottom impact.[64]

The Military Liaison Committee notified the Division of Military Application, October 3, 1952, that no requirement existed for design of penetration warheads capable of impact velocities higher than those of the REGULUS missile.[65]

Meanwhile, the Military decided that efficient use of the XW-8/REGULUS weapon required a high delivery accuracy. This was not possible with the existing missile system, and production requirements were deferred, awaiting refinement of the missile guidance system. Sandia was requested to complete its design work on the warhead, and the Navy was asked to proceed with scheduled flight tests.[66]

Successful component evaluation flights were conducted, and a successful warhead system test was held September 24, 1953. The Military Liaison Committee then suggested that, since there were few differences between the XW-8 Warhead and the extensively tested Mk 8 Bomb, further systems tests be held in abeyance.[67]



Design of the missile-warhead was completed in August 1954, and Report SC3483(TR), Status and Evaluation of the XW-8/REGULUS Warhead Installation at Design Release, was presented to the December 1, 1954 meeting of the Special Weapons Development Board.[68] The warhead was named the Mk 8 Mod 2, and production responsibility assigned to the Bureau of Ordnance.

The warhead contained three delay fuzes, two located on the side and one on the nose. (b)(3)

All requirements of the military characteristics were satisfied by the test program, although impact tests at less than 90 degrees were not conducted, and it was

not definitely determined whether the warhead would penetrate the target or break away on impact. However, Mk 8 Bomb tests had shown that satisfactory penetrations were achieved at entry angles as low as 30 degrees to the surface, and it was felt that the warhead would have similar satisfactory characteristics.

Subsequently, the possibility of developing a guidance system to effectively deliver the XW-8/REGULUS with pinpoint accuracy appeared remote. Consequently, on May 20, 1955, the Navy suspended activity in the program, together with work on the XW-11/REGULUS application.[69]

TX-10 External View

Subsequently, the Division of Military Application proposed that a lightweight, air-burst, gun-type missile warhead be developed,[74] and this suggestion received the backing of the Military Liaison Committee July 6, 1950.[75] It was proposed that Army Ordnance, then involved with the Mk 9 Shell, be requested to assist in design and development.[76]

Meanwhile, the lightweight, air-burst, gun-type bomb project had not been entirely forgotten, and the Military Liaison Committee, in a letter dated August 9, 1950, stated that the Joint Chiefs of Staff had established a requirement for the development of air-burst bombs sufficiently light in weight and small in cross section to be carried by high-speed tactical airplanes of the Air Force and Navy. It was felt that these bombs could be based on either implosion- or gun-type nuclear devices, and formal requests were made for both types.[77]

The subject was discussed in the August 16, 1950 meeting of the Sandia Weapons Development Board, with the Board agreeing to assume cognizance of the project. Two problems were immediately apparent: The development of a flexible fuzing system capable of attacking various tactical targets, and a weapon resistant to temperatures as low as -100°F.[78]

Sandia had meanwhile made a study of a lightweight bomb design and reported to AEC-Sandia August 17, 1950, that this could be produced by mid-1952. It was suggested that North American Aviation, Inc., be assigned the task of developing and manufacturing the outer case, internal support structures, and parts of the carrying pylon. Sandia would develop a fuzing and firing system, conduct drop tests, provide test and handling equipment, and act as project coordinator.[79]

On the same date, the Division of Military Application forwarded military characteristics for the above bomb. These required that the bomb be capable of tactical use by fighter, light bombardment, and attack (dive bomber) aircraft. The primary requirement was for external carriage, with alternate internal carriage being desired.

(b)(1), (b)(3)

The TX-G or Gun Committee agreed to accept interlaboratory responsibility for the TX-10.[26] The program was subjected to an intensive review in a Committee meeting of December 14, 1950, with the TX-10 being compared with the TX-7, an implosion design that had been pushed rapidly and which was now scheduled to enter stockpile earlier than the TX-10. It was felt by some conferees that the basic need for the TX-10 was eliminated by the advent of the TX-7. This latter weapon was larger than the proposed diameter of the TX-10 (27 inches versus 17 inches), but there appeared to be a sufficient variety of airplanes that could carry the TX-7.

(b)(1), (b)(3)

The problem was referred to the Sandia Weapons Development Board and discussed in a meeting December 20, 1950, with the Board being furnished copies of Sandia Report SC-1684(TR), A Critical Comparison Between the TX-7 and TX-10 Programs. This report noted that design was in work on a follow-on (and smaller) implosion device for the TX-7 (to be called the TX-12). The TX-12 would be less costly from the nuclear standpoint, would offer greater chances of increasing nuclear efficiency, and could be developed in about the same time scales. It was pointed out that work on the TX-10 would subtract effort from the TX-12, and that tactical use of the TX-10 (if manufactured in large numbers) would require major realignment of component production.

The Board noted that the TX-10 diameter would probably be smaller than the TX-7 or TX-12, but stated that further reductions in implosion-weapon diameter could be expected, as much nuclear design effort was currently being placed on implosion design improvements. After extensive discussion, the Board recommended that the TX-10 development be dropped in favor of the TX-12.[89]

The Division of Military Application wrote to Santa Fe Operations Office January 3, 1951, making reference to the above meeting. There were hopes that an interim TX-10 could be made available earlier than the TX-12, and it was suggested that the requirement for nuclear safing be eliminated and an external shape suitable for subsonic (but not necessarily supersonic) carriage be provided.[90]

The design status of the TX-10 was reviewed in the April 10, 1951 meeting of the Sandia Weapons Development Board. The bomb would be at least 17 inches in diameter and 2000 pounds in weight.

(b)(3), (b)(1)

The Board noted that the diameter and weight of the TX-10 exceeded the military characteristics, and that major reductions in these items could not be expected until the nuclear gun design was revised by Los Alamos.

(b)(3)

The project thus reverted to fundamental study of the problems of providing low burst heights, miniaturization, supersonic aerodynamics, and nuclear design improvements. Subsequently, the Military Liaison Committee canceled the TX-10 Bomb program May 7, 1952, noting that the Joint Chiefs of Staff had stated that a military requirement for the weapon no longer existed.

RESTRICTED DATA

Mk 11 Weapon

The Mk 11 Bomb, a gun-type penetrating weapon to be externally carried on high-speed aircraft, had its early beginnings when the gun-type device was considered for guided-missile application in March 1950. In this usage nuclear safing would be required to protect the missile launching site, and it would be necessary for the warhead to survive high impact velocities.[47]

Subsequently, the Division of Military Application expressed interest in a gun-type bomb that could be nuclearly safed and externally carried on high-speed aircraft.[99] The external shape of the Mk 8 did not lend itself to such carriage (due chiefly to its blunt nose), and it was felt that any modification of the nose shape would be complicated by the existence of the nose fuze. A nose redesign would require a lengthy effort, and it was suggested that a development program be authorized for a Mk II Elsie for such usage.[100]

The Military Liaison Committee released a set of desired military and technical characteristics for impact, delayed-action atomic bombs April 17, 1950. These characteristics described a bomb which could be nuclearly safed during aircraft carriage and that would be suitable for release at speeds up to Mach 1.2.[54] Subsequently, July 31, 1950, the Division of Military Application requested the Bureau of Ordnance to design a Mk 8-type weapon meeting these characteristics, and offered Sandia assistance in the task of fitting the design to appropriate carrying aircraft.[101] This proposal was accepted by the Bureau of Ordnance,[102] and nomenclature of TX-11 was assigned to the project November 29, 1950.[103]

There were three main gun-weapon problems being studied at this time: The ballistics problem relating to external carriage and release at high speeds; the nuclear safing problem, which concerned missiles as well as bombs; and the problem of increasing the resistance of the weapon to impacts on hard targets, such as reinforced concrete, rock and armor plate.

The Naval Ordnance Laboratory started to design the TX-11 fuzing system. It was felt that feasibility and preliminary design studies to establish tentative characteristics could be completed by January 1, 1952; and that detailed design

toss, glide and dive bombing. It would be capable of carriage and release at speeds up to Mach 1.4 and altitudes of 50,000 feet. It would be able to function satisfactorily after impacts on water, soil, reinforced concrete, and--to the extent practicable--harder targets.

The Board noted that the characteristics required external carriage at both subsonic and supersonic speeds, but a shape designed for one of these velocities would not be optimum for the other. It was felt that the design should be based on the assumption that the least drag during the major portion of the flight was desirable. Inasmuch as jet fighters en route to a target cruised at subsonic speeds, the bomb shape should be designed to meet this requirement.

The desire that the weapon be capable of penetration into hard rock was of concern. It was difficult to suitably define "hard rock," and there was felt to be a low incidence of this type of terrain near any probable targets. The scheduled design-release date was established as October 1953, with the bomb to enter stockpile in January 1955.[34]

The Bureau of Ordnance had been conducting tests of a soft-steel nose cap which, it was hoped, would crush and absorb the shock of weapon impact. These tests were not encouraging, and it was eventually decided to provide a Fiberglas nose cap. When the bomb was to be carried in an internal bomb bay, this nose cap could be removed.

Wind-tunnel tests had meanwhile narrowed the choice of weapon length to two possibilities; 146 and 169 inches. The Bureau of Ordnance recommended that the shorter figure be selected: It caused less drag at subsonic speed, it was compatible with all aircraft being considered for carriage of the bomb, and it could be carried internally in all aircraft except the B-50 without removing the nose cap.[109]

Full-scale drops at Inyokern produced excellent results.

(b)(1), (b)(3)

No detonation of the high explosive occurred during any of the impacts. Tests of 6-1/4-inch-diameter scale models against reinforced concrete 10 feet thick demonstrated that impact velocities between 2000 and 2200 feet per second could be

absorbed.[110] As a result of these tests, the length of the TX-11 was frozen at 146 inches on June 30, 1952, and the fin size was established at two bomb diameters, or 28 inches.[111]

Meanwhile, work had been undertaken on the design of a nuclear safing system,

(b)(3)

The fuzes were mechanically armed and were of a pyrotechnic design similar to those used in the Mk 8.

RESTRICTED DATA
UNCLASSIFIED

Joint Research and Development Board -- A Board established in mid-1946 as a postwar replacement for the Office of Scientific Research and Development. Its purpose was to suggest lines of research and development on military weapons and equipment.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Little Boy -- Code name for the gun-type weapon dropped on Hiroshima, Japan, August 6, 1945, during World War II. Originally called the Thin Man in reference to its long thin shape. The Thin Man was to use plutonium-239 as its nuclear material. Early samples of this isotope revealed that it contained small amounts of plutonium-240 which had a high preinitiation rate. A decision was then made to use uranium-235, allowing the length of the weapon to be radically reduced (due to the lower speed of assembly of the critical material). This change in outer shape was given the code name of Little Boy.

Los Alamos Scientific Laboratory -- A nuclear design organization located at Los Alamos, New Mexico. Called the Los Alamos Laboratory during World War II.

Mach -- A measure of speed. Mach 1.0 is the speed of sound, or 738 miles per hour at sea level.

Manhattan Engineer District -- A District of the Army Engineers established in August 1942 to provide the facilities that would be needed for design and construction of the atomic bomb.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

A En r v t Man n t l E

s A i ro e o o y s I

Naval Ordnance Laboratory -- A portion of the Bureau of Ordnance devoted to design and test of Naval ordnance.

Neutron -- An uncharged particle of slightly greater mass than the proton.

Operation Crossroads -- See Crossroads.

Pitch -- Motion of the bomb as it falls through the air, such that the nose and tail alternately rise and fall.

Proton -- The nucleus of the atom of the light isotope of hydrogen. It has a unit positive charge of electricity.

Prototype -- An early weapon type, generally hand-produced before a production run.

Pylon -- A strut to hold bomb in position below an airplane wing.

Pyrotechnic Fuze -- A fuze that operates by burning or detonation of a small charge of explosive.

Radar -- Named for Radio Detecting and Ranging. Radars emit a pulse of high-frequency energy and measure the time lapse from that transmission to receipt of a reflected electrical "echo" from an object. This time measurement determines the distance of the object from the transmitting antenna of the radar.

Ricochet -- A glancing rebound of a missile when it strikes a target.

Safing -- Putting a weapon in condition such that it cannot fire.

Salton Sea Test Base -- Located on the site of a Naval Auxiliary Air Station on the shores of Salton Sea, California. One of the early sites for ballistic tests of atomic bombs.

Sandia Research and Development Board -- A joint Sandia-Military board formed March 2, 1948, at Sandia Base to provide local guidance on weapons design.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent of uranium-238; the rest is uranium-235.

Z Division -- A division of the Los Alamos Scientific Laboratory, elements of which moved to Sandia Base and became the nucleus of Sandia Laboratory and Corporation.

History of Gun-Type Artillery-Fired Atomic Projectiles

Mk 9 Shell

The possibility of developing an artillery-delivered gun-type atomic device was discussed in late 1949 by Army Ordnance. This shell would be a defensive or offensive weapon against infantry masses concentrated in front of the sector through which a breakthrough was planned. It was hoped that a nuclear artillery shell, fuzed for air burst, could destroy the ability of these troops to stage an attack, or to defend the sector.

Possible delivery methods considered for such a weapon included railway rifles, guided missiles, aircraft, or artillery field pieces. Railway rifles, besides being almost obsolete, were ruled out due to heavy weight and relative immobility. Guided missiles capable of carrying atomic warheads were not as yet available. Bombing inaccuracy and difficulty in identifying battlefield targets made use of aircraft-delivered weapons unattractive.

It was felt, however, that artillery field pieces could be used, at least until suitable guided missiles became available. Army Ordnance had developed a mobile gun of 240-mm diameter (about 9-1/2 inches), weighing 90 tons, which was soon to be proof-fired, and a conference was held with Los Alamos Scientific Laboratory personnel November 10, 1949, at which use of this gun was advocated. The nuclear designers stated that a gun-type nuclear device would fit inside a 240-mm gun barrel, although concern was felt about the relatively inefficient usage of fissionable material in such an assembly.[1]

Another meeting was held on the same subject January 16-17, 1950. Increased Los Alamos interest in the project had developed, and Army Ordnance representatives discussed possible shell designs. One proposal was to develop a 240-mm-diameter shell, to fit the mobile gun, and another was to install a 280-mm barrel on the 240-mm mount, thus allowing the shell diameter to increase to about 11 inches.[2]

AFAP (Artillery-Fired Atomic Projectile), and Button (possibly because it was predicted that the shell could be delivered "right on the button").

The Ordnance Department proposed a set of military characteristics that were considered in a Button Committee meeting of August 11, 1950, and accepted on a preliminary basis.[9] The shell would weigh about 890 pounds and be fired with a muzzle velocity of 1700 feet per second from a 280-mm gun mounted on a 240-mm carriage.

(b)(1), (b)(3)

The shell would be able to withstand temperatures from -65°F to +160°F during storage and transportation, and operating-temperature limitations would be determined by the gun itself.[10]

(b)(1), (b)(3) A device would be designed to provide a surface burst, and it was hoped that this feature could be available concurrently with the time fuze.

The Button Coordination Committee was dissolved October 23, 1950, with Santa Fe Operations Office noting that the number and variety of weapons currently being developed necessitated the establishment of a uniform policy for assignment of responsibilities. Button was in full development but not yet scheduled for production, and Los Alamos and Sandia were requested to assume normal project responsibilities.[12] Subsequently, Sandia took over control of the nonnuclear phases of Button, and reassigned many of the design tasks to Army Ordnance.

(b)(1), (b)(3)

This

(b)(1), (b)(3)

However, subsequent design improvements, selection of high-quality component parts, and eventually, the use of three parallel fuzes, increased operational reliability to the point where timer fuzes were felt to be satisfactory.

Prototype shells were being fired by mid-1951, and demonstrated that nuclear assembly was taking place at the proper point in the trajectory.

(b)(1), (b)(3)

This created a maximum force of 3800 g's. The design of a lighter version with longer range was considered, but the higher stresses involved in this design caused later abandonment of this modification.

(b)(1), (b)(3)

UNCLASSIFIED

A proposed TX-9 status and characteristics report was prepared by the TX-G Committee. This noted that development of the TX-9 had been telescoped to such an extent that much of the testing would have to be conducted after the design had been released to production.

(b)(1), (b)(3)

Three independently operating mechanical time fuzes were located near the nose of the shell.

(b)(1), (b)(3)

The TX-G Committee met November 2, 1951, and noted that much TX-9 work remained to be done, including testing of the initiators, fuzes, and the conduct of a full-scale nuclear test; and that temperature limitations on both shell and gun were yet to be established. However, the stockpile date would not permit

UNCLASSIFIED

delaying design freeze. There had been no formal issuance of the military characteristics, but the Committee felt that the TX-9 design was adequate for operational use.[22] Design release was accordingly issued November 15, 1951.[23]

The Sandia Weapons Development Board, meeting January 16, 1952, recommended that the TX-9 be released "to" (rather than "for") production.[24] The choice of preposition indicated that the weapon, in some respects such as tests and drawings, was not at the normal stage of release for full production activity.[25] The weapon system was praised for its mobility, and it was noted that the gun could be emplaced in 15 minutes, and that the same length of time was required to assemble and fire the nuclear round.

(b)(1), (b)(3)

The Sandia Weapons Development Board, February 11, 1952, again recommended that the TX-9 be released to production,[26] and this was accepted by the Military Liaison Committee April 14, 1952.[27]

Initial deliveries of the TX-9 to stockpile were made in April 1952, right on schedule. Since the military characteristics had not been issued and the testing program was not completed, these units were temporarily designated as PM-9 or Pre-Mark, rather than by the more formal title of Mk 9 Mod 0.[28]

The military characteristics were officially released by the Military Liaison Committee July 18, 1952.[29]

(b)(1), (b)(3)

(b)(1), (b)(3)

The shell would be able to withstand 100-percent humidity and temperatures up to 90°F.[30]

Sandia recommended to Santa Fe Operations Office October 14, 1952, that the Mk 9 Mod 0 Shell be approved for operational suitability, training, and emergency use, based on examination of 12 early-production shells from Picatinny Arsenal. This proposal was accepted, and the first War Reserve-quality shells, the Mk 9 Mod 0-ZZ, were accepted for stockpiling in October 1952 (ZZ was the nuclear identification).[31]

(b)(1), (b)(3)

The controllable arming feature of the military characteristics was given attention. The TX-G Committee took this under consideration, but later noted that it would be difficult to develop and might degrade the reliability of the shell due to its complexity.[34] The Committee reported that modification to the Mk 9 Mod 0, to bring it in line with all the military characteristics, would require much design and testing, and suggested that this work be assigned to the Ordnance Corps. It was felt that the need for TX-G Committee direction was

declining, and that it could be replaced by an Ad Hoc Committee for each weapon. On December 15, 1952, the Atomic Energy Commission requested the Military Liaison Committee to transfer responsibility for nonnuclear components of the Mk 9 to the Army, but no action was taken.

The testing program required telemetering of internal events in the Mk 9 Shell, and this posed a difficult problem.

(b)(1), (b)(3)

Sandia had meanwhile concluded that a rugged and accurate telemetering system would be needed for rockets and guided missiles, and started to work on the problem.[36] This was a major undertaking, due to the 5000-g acceleration experienced by the shell. Additionally, the limited space available in the shell case demanded extreme circuit simplicity, and antenna design was severely restricted by the requirement that the external ballistic shape remain unchanged.

Both Army Ordnance and Sandia prepared designs of telemetering systems, and the results were evaluated in a TX-G Committee meeting September 18, 1952. The Ordnance system contained two channels with microsecond time resolution and four with millisecond time resolution. Sandia provided a dual system, each having five channels with microsecond and six with millisecond time resolution.

(b)(1), (b)(3)

The Picatinny system, being immediately available, was used for the first tests, and was later replaced by the Sandia system.[34]

The Sandia telemetering system was tested at Aberdeen in mid-December 1952. Results were generally satisfactory, but swampy terrain prohibited efficient location of telemetering receiving stations, and the range was too short for the maximum range of the Mk 9.[37] A proposal was made that the telemetering tests be conducted at the Nevada Test Site, but the location was later changed

to Ft. Sill, Oklahoma, home of The Artillery Center. These tests were held from January 19, 1954, to February 5, 1954, with 19 rounds being fired. Telemetering results were excellent, as was the performance of the Mk 9 Shell.[38]

A full-scale test of the Mk 9 had meanwhile been proposed, both to provide the Army with an operational test and to allow effects studies, both nuclear and military.[39] A decision was made in late 1952 to conduct this test in Operation Upshot-Knothole at the Nevada Test Site,[40] and the Mk 9 Mod 0-ZZ Shell was successfully tested in Shot Grable May 23, 1953.

Some study had been given to updating the stockpiled PM-9's to Mark status. However, it was felt that the PM-9 was entirely adequate, and that conversion was not required. Production of the Mk 9 was completed November 1953.

In April 1957, the Mk 9 was replaced in stockpile by the Mk 19 Shell. Mk 9 Shells, tools, and test and handling equipment were transferred to the Army for training and test purposes.

Mk 19 Shell

By late 1952 it was felt possible to reduce the weight of the Mk 9 Shell by about 200 pounds. This would produce a shell with the same (280-mm or 11-inch) diameter as the Mk 9, but with longer range and higher yield. The proposed atomic projectile would have the same weight as conventional high-explosive 280-mm shells, making it unnecessary to provide special spotting rounds, firing tables, or propellant charges. The Army Ordnance Corps authorized this new project March 1953, and the design of this Shell, called by the Army the T315 or Button II, became the first item of business for the Acorn Committee, which was established April 2, 1953, to centralize work on gun-type weapons.

(b)(1), (b)(3)

The Division of Military Application authorized development of this program, called the TX-19 Shell, April 28, 1953.[42]

(b)(1), (b)(3)

Sandia entered the program in June 1954, when the Atomic Energy Commission requested it to provide inflight telemetry for the projectile firing tests.[45] Sandia developed a system by which the internal nuclear events, such as assembly of the subcritical portions of the gun, were monitored.

(b)(1), (b)(3)

The Shell would be 53.62 inches long, about an inch shorter than the Mk 9. The sequence of operation would be identical to the Mk 9, and the two shells would be externally very similar.

(b)(1), (b)(3)

The Army withdrew the requirement for controllable arming. New mechanical fuzes were developed, which were more easily set than those in the Mk 9. Tests were made of an impact device, to determine whether it was safe enough for use, but it did not become available in time.

Stockpiling of the nonnuclear parts of the new weapon started in July 1955.[46] Operational suitability tests were conducted in August 1955, and the Mk 19 was declared satisfactory for field use.

(b)(1), (b)(3)

The increased launching stresses due to the lighter weight required some redesign and strengthening of parts of the ignition, fuzing and safing systems.

The nose fuze and the two internal fuzes of the Mk 19 had redesigned setting features. Settings on the internal fuzes were made with a closed-end ratchet wrench that allowed more rapid and accurate positioning. All fuzes were set in a clockwise direction, facing the nose of the shell, to prevent backlash on firing.[44]

Mk 23 Shell

The development requirements for a 16-inch atomic projectile were forwarded by the Military Liaison Committee to the Division of Military Application December 28, 1953. These called for the design of a shell to be fired from Naval 16-inch rifles and which would use Mk 19 nuclear components.[47] The project, known as Katie, would develop a shell that could be used for atomic support during amphibious operations.

A design-release date of December 31, 1954, was proposed, with stockpiling by July 1955. The task was a relatively straightforward one; that of adapting the features of the 280-mm T315 (Mk 19) Shell to a case whose external configuration was that of the Navy 16-inch HC Projectile Mk 13.

(b)(1), (b)(3)

Nomenclature of TX-23 was assigned by Sandia March 30, 1954, and was Sandia's only involvement with the project, other than the work being accomplished on the Mk 19, which was also applicable to the Mk 23.[48]

(b)(1), (b)(3)

It was hoped to provide contact cleanup, but on a not-to-delay basis.[50]

The military characteristics were approved by the Military Liaison Committee in mid-1955. The fuzing system would be rugged, reliable, and easily set or reset.

(b)(1), (b)(3)

The shell would function in a temperature range from 0°F to 125°F, and preparation for firing would require no more than 15 minutes.[52] These characteristics were reviewed without comment by Sandia August 15, 1955.[53]

The status of the Mk 23 was discussed in the December 12, 1956 meeting of the Special Weapons Development Board. The shell had a diameter of 16 inches, a length of 63.7 inches, and a weight of 1900 pounds

(b)(1), (b)(3)

The fuzing system contained three independent mechanical time fuzes in the nose of the projectile.

(b)(1), (b)(3)

The Mk 23 was stockpiled, and initial units delivered to the Fleet in October 1956.[54] These initial deliveries were made during the same period that the Navy retired the last 16-inch rifle from active use.

TX-32 Shell

The Division of Military Application, May 5, 1954, requested the Santa Fe Operations Office to develop a 240-mm (~~8.465~~ 9.45 inch) atomic shell, using the Mk 9 gun-type nuclear components. This design would provide a shell for the Army's 240-mm howitzer. Full-scale development activities were subsequently authorized by the Santa Fe Operations Office, subject to availability of funds and to orderly integration of the project into the Los Alamos program.[55]

The Military characteristics for a Shell, AE, 240-mm, T332, were released by the Division of Military Application June 18, 1954. The Army would manage the project, and the Atomic Energy Commission would furnish nuclear design and components.[56]

(b)(1), (b)(3)

The design was canceled in May 1955, in favor of an 8-inch implosion design, the XW-48, which had been proposed by the University of California Radiation Laboratory.[58]

The design was made available July 1955, for emergency capability use with the 8-inch howitzer M-2.

SECRET
RESTRICTED DATA

(b)(1), (b)(3)

LENGTH—116 IN
DIAMETER—14.5 IN.
WEIGHT—3150 LBS

Mk 8 Cross Section

12/8/50	TX-G Steering Committee appointed and holds initial meeting.
1/26/51	
	(b)(3)
3/15/51	
Early 1951	Externally carried TX-8 Bomb assigned nomenclature of TX-8 Prime.
10/51	TX-8 Prime program divided into two parts: TX-8-X1 (to cover carriage at subsonic speeds) and TX-8-X2 (a program to reduce drag in high-speed carriage).
11/51	Mk 8 Mod 0 achieves production.
1/52	Mk 8 Mod 0 enters stockpile.
4/1/52	
	(b)(3)
9/53	Mk 8 Bomb with Mk 8 Mod 1 Fuze (TX-8-X2) enters stockpile.
11/55	Mk 8 Mod 3 Bomb enters stockpile.
5/57	Mk 8 Bombs retired as Mk 11 enters stockpile.

Mk 8 Warhead

3/50	Gun-type warheads considered for missile application.
9/13/50	Santa Fe Operations Office requests that penetrating warheads be applied to guided missiles.
2/14/51	Santa Fe Operations Office authorizes design of XW-8/REGULUS.
1/18/52	XW-5/REGULUS program assigned priority over XW-8/REGULUS.
8/21/52	Field Command forwards proposed military characteristics for XW-8/REGULUS to Sandia.
9/24/53	Successful XW-8/REGULUS system test held.

8/54 Design of XW-8/REGULUS completed.

5/20/55 Program activity suspended.

TX-10 Weapon

5/6/48 Sandia Research and Development Board assigns priorities to weapon design projects.

1/21/49 Division of Military Application requests Bureau of Ordnance to study possible adaptation of Mk 8 as a light air-burst weapon.

4/22/49 Military Liaison Committee requests that study be restricted to a preliminary investigation.

3/8/50 Guided-missile symposium at Sandia Base proposes use of a light-weight gun-type device as a missile warhead.

7/6/50 Military Liaison Committee releases formal requirement for an air-burst, gun-type warhead.

8/9/50 Military Liaison Committee establishes formal requirement for a lightweight air-turst bomb.

8/17/50 Division of Military Application forwards characteristics for lightweight air-burst bombs.

9/6/50 Bureau of Ordnance, in reply to January 21, 1949 request of the Division of Military Application, offers to adapt the Mk 8 as a lightweight air-burst bomb.

10/3/50 Division of Military Application notifies Bureau of Ordnance that Sandia will develop the lightweight air-burst bomb.

10/18/50 Sandia Weapons Development Board discusses bomb and warhead applications. Santa Fe Operations Office subsequently authorizes deletion of warhead requirement. Bomb officially designated the TX-10.

SECRET
RESTRICTED DATA

4/1/55 Mk 11 design released.

1/1/56 Early production units of Mk 11 (Mk 91 Mod 0) become available.

7/1/56 Mk 91 Mod 0 enters stockpile.

8/56

(b)(3)

History of Gun-Type Bombs and Warheads

Mk 8 Bomb

The gun method of assembling nuclear material, used in the wartime Little Boy design, was the first atomic weapon system to be devised, predating the establishment of the Los Alamos Laboratory. The method was nuclearly inefficient and was largely ignored for a time after the end of World War II, while interest centered on implosion techniques.

(b)(1), (b)(3)

At this time, the Los Alamos Scientific Laboratory was fully occupied in the above-mentioned study of improvements in implosion devices, and suggested that the task of developing a water-penetrating weapon (which probably would use gun techniques) could best be accomplished by a military group. No immediate action was taken on this suggestion, but the subject was briefly examined by the Z Division of Los Alamos in late 1946 and early 1947.

(b)(1), (b)(3)

The topic was subsequently discussed in a meeting of the Weapons Subcommittee of the AEC General Advisory Committee, and a decision made May 15, 1947 that consideration of a penetrating weapon be postponed.[4]

Meanwhile, however, the Military Liaison Committee had been discussing the general subject of subsurface atomic weapons. At the instigation of the Navy member, Rear Admiral William S. Parsons (who had armed the wartime gun-type Little Boy for

its historic drop on Hiroshima), Section ReM of the Navy's Bureau of Ordnance, prepared preliminary sketches of a penetrating gun device.

At about the same time, other groups were considering the same subject. The Joint Research and Development Board had established a Committee on Atomic Energy, and the subject of penetrating weapons was discussed in the October 2, 1947 meeting of this Committee. It was urged that serious consideration be given to the development of a gun-type device suitable for penetration use. Since the AEC weapon laboratories were already fully occupied with other high-priority work, the Committee recommended that the facilities of the Bureau of Ordnance be used.[5]

The Division of Military Application had also been considering the advisability of invoking the assistance of the military services in the development of penetrating weapons. Los Alamos had noted that gun systems were inherently inefficient, and expressed an opinion that the weapons laboratories should continue to concentrate on design of implosion devices.[6] Thus the Military Liaison Committee was requested to assign mechanical design of a gun-type penetration weapon to the Bureau of Ordnance.[7]

These several requests, all in the same vein, were presented for consideration to the Military Liaison Committee which, April 9, 1948, requested the Atomic Energy Commission to undertake development of a penetrating-type weapon, using the facilities of the Bureau of Ordnance.[8] This request was formally presented to the Bureau April 27, 1948, and accepted.[9] A code name of "Minnie" was initially assigned to the project, but was later found to have been used for a Bureau of Ships propulsion project and, in mid-July 1948, the name was changed to "LC" (a follow-on term to "LB," for the Little Boy), and which came to be commonly written as "Elsie."[10] That the Elsie program was considered a matter of some interest to the Military was indicated in a May 6, 1948 meeting of the Sandia Research and Development Board in which the project was assigned top priority, second only to the schedule for getting the Mk 4 Bomb into full-scale production.

The Bureau of Ordnance issued detailed work assignments. The Naval Ordnance Laboratory would be responsible for developing suitable pyrotechnic delay fuzes.

The Naval Ordnance Test Station would study external ballistics and design the tail. The Naval Powder Factory would investigate powder development. The Naval Ordnance Plant would handle much of the manufacturing and testing program, and when this location was subsequently closed, the work would be transferred to the Naval Proving Grounds and the Naval Gun Factory. Section ReM of the Bureau of Ordnance would provide overall design controls, including the task of guaranteeing survival of the nuclear assembly under impact conditions.

The development program would proceed in three overlapping phases. Feasibility and preliminary design studies would outline the most promising general design characteristics of the weapon, and these were scheduled for completion January 1, 1949. The second phase, covering experimental development and testing of prototype weapon design, would be completed a year later. The third phase, manufacture of prototype weapons, would be finished in another year, or January 1, 1951.

(b)(3)

The studies advanced rapidly and, by September 3, 1948, the Bureau of Ordnance could report that the design appeared feasible and that a weapon could probably be devised that would function satisfactorily after impact on water, and possibly after impact on hard surfaces which the weapon might encounter beneath the surface of the water.[11] It was initially felt that the fuze should be actuated at impact and have a delay of 1 to 2 minutes before bomb detonation, but it was later decided that a more reliable bomb would be created if the fuze action were initiated at time of release of the bomb from the carrying aircraft.

The diameter of the bomb would be about 14 inches and the weight would be about 3000 pounds, as compared to 28 inches and 8900 pounds for the Little Boy. These reductions were due to the more compact nuclear assembly and a decrease in the thickness of the bomb case. The shape would be roughly cylindrical, with a flat nose for good penetration characteristics, and the bomb would attain a maximum impact velocity of 1500 feet per second. The minimum release altitude would be 500 feet, to give the bomb enough time during its fall to assume proper entry attitude, and there would be no restriction on maximum release altitude. It was felt that three separate and independent fuzes should be used, to provide adequate relisbility. A meeting was held October 25 and 26, 1948, with Los Alamos assuming the task of developing impact-resistant initiators.[12]

An extensive series of tests was performed. The first group included 174 half-scale bombs of 6.25-inch diameter. These were fabricated in 49 different configurations, and were impacted against targets of steel and concrete at different angles, striking velocities, and missile temperatures ranging from -65°F to +165°F.

(b)(3)

Following the above, some 38 full-scale impact tests were conducted, to confirm the half-scale results. Interior ballistic tests were performed, to check the burning rate of various propellants and the behavior of the missile in the gun barrel. As fuze components became available, they were subjected to the shock produced by firing from a 14.25-inch-diameter railway gun.

Two series of wind-tunnel tests were held, one at the University of Minnesota to obtain aerodynamic coefficients of various tail configurations, and the other at the California Institute of Technology Cooperative Wind Tunnel to evaluate aerodynamic characteristics of five basic designs.

This paper was circulated for comment to Sandia and Los Alamos as well as the Military, and was subjected to a critical review.[23] The formal issue of the characteristics on November 10, 1950, however, retained the release speed requirement and noted that the bomb should function reliably when released at any altitude up to 50,000 feet and survive impacts on water, reinforced concrete, and--hopefully--thin steel plate.

(b)(3)

The November 22, 1950 meeting of the Sandia Weapons Development Board reviewed the overall gun-type weapons program, which now included the TX-9, TX-10, and TX-11, in addition to the TX-8. It was noted that the TX-8 was composed of three main parts: The nose, the tail, and the clamping ring which joined them. The bomb diameter had been fixed at 14.5 inches, its length at 116 inches, and its weight at 3260 pounds. The nose was a heavy forging with a blunt shape for water and ground entry, and contained the internal gun barrel, tamper, and projectile.

(b)(3)

A saddle on the external top of the bomb case contained switches and electrical connections to operate the primers.[25]

Sandia had proposed that an interlaboratory gun-type weapon coordination committee be established, similar in scope and authority to the TX-5 Steering Committee. Action was taken on this suggestion in late 1950, and the first meeting of this Gun Committee, with representation from Los Alamos and Sandia, was held December 8, 1950.[26] At this time, the TX-5 Steering Committee was renamed the TX-N Steering Committee to reflect its interest in all implosion weapons, and the new Gun Committee came to be known as the TX-G Steering Committee.

The first meeting of the TX-G Committee heard a report from Los Alamos concerning progress on design of an initiator for the TX-8. The initial design had been based on the device used in the Little Boy, and was then modified as design weaknesses were uncovered by the testing program. Some idea of the problems encountered were shown by the increasing impact requirements as the design progressed. The initial

assumption had been that the highest shock encountered in ground impact would be 7500 g's. This figure had progressively increased during design and was now 100,000 to 300,000 g's.

(b)(3)

Studies were meanwhile in progress on systems for nuclear safing.

(b)(3)

In early 1951 it was decided to identify the adaptation of the TX-8 for external carriage at subsonic speeds as the TX-8' (or TX-8 Prime) program. Plans were made to make only minor changes to the TX-8 and provide early, but only partial, satisfaction of the requirements for an externally carried TX-8. It was felt that, if this program could not be accomplished within a short time, it should be canceled in favor of the TX-11 Bomb, then being designed for external carriage on high-speed aircraft.

At this time, the AD4 and the F4U5 were the only carriers specified for the TX-8'. The AD4 was selected as the test aircraft, and Sandia issued a contract through the Bureau of Aeronautics to Douglas Aircraft Company to modify this aircraft for TX-8 carriage. Douglas designed a nose cap to reduce drag and help protect the TX-8' fuzing elements.

In late October 1951, the TX-8' program was divided into two parts; the TX-8-X1 and TX-8-X2. The X1 was the basic TX-8' program; the X2 was to provide a cleaner aerodynamic design and reduce the drag caused by the saddle. Inasmuch as 20 drops had already been made with the TX-8-X1, its compatibility and reliability were felt to have been proven, and attention was concentrated on the TX-8-X2 design.[33]

The T-28 saddle functions were replaced by a small box located in the aircraft fuselage. This allowed the use of a standard two-hook bomb rack and increased the clearance between the externally carried bomb and the ground. Fairings were installed over the side fuzes to reduce drag. Fuze tapes used for safing were pulled through the nose fairing to protect them from the windstream. A quick disconnect was installed, to permit the weapon to be dropped with tapes in place, thus leaving barriers in the path between the primer and the propellant, and preventing the fuzes from firing the main propellant charge.

This new device was called the T-31, and a subcontract was issued for its development. Due to the subsequent failure of the subcontractor to achieve a satisfactory T-31, Sandia produced a design having the T-31 located inside the bomb pylon, thus making it possible to detach the arming tapes from the pylon after bomb release, and prevent aircraft damage caused by whipping of the tapes in the slipstream. This work was undertaken November 5, 1951, and satisfactory hardware was being produced 10 days later.

The Mk 8 Mod 0 weapon was initially produced in November 1951 and was stockpiled in January 1952.

(b)(1), (b)(3)

The Military Liaison Committee, in a letter dated October 20, 1952, requested that the bomb be designed to withstand storage for 6-month periods under occasional temperature extremes of -80°F to +165°F, and flight bomb-bay temperatures of -90°F. It was pointed out that external bomb carriage might experience even more rigorous conditions of -100°F during a 12-hour flight, and that the 24-hour limitation regarding weapon assembly would be operationally troublesome.[40]

Inasmuch as the propellant characteristics were specified by the Bureau of Ordnance, the problem was referred to this organization.[41] It was noted that the environmental criteria had been specified after detail design of the Mk 8 had been essentially completed, and that these criteria differed considerably from the initial Mk 8 development objectives. It was also pointed out that any project to provide a propellant with improved temperature characteristics would duplicate work being undertaken in the TX-11 program. The Bureau of Ordnance subsequently allowed relaxation of the temperature limitations to 7 days at 130°F, 60 days at 120°F, and indefinitely at 110°F.[42] On March 12, 1953, the Military Liaison Committee agreed that major redesign efforts toward relieving temperature limits be directed toward the TX-11.[43]

The possibility of water leakage into the interior of the gun nuclear system had been a matter of early concern.

(b)(1), (b)(3)

When recovered, there was only about half a cup of water in the barrel, and this leakage was not felt great. Nevertheless, the Military, in the April 16, 1952 meeting of the Sandia Weapons Development Board, requested that the possible effects of this leakage on weapon performance be studied.[38]

Consequently, drops were made on a limestone bed in southwestern New Mexico. This rock possessed extremely high compressive strengths, from 18,000 to 23,000 pounds per square inch (average concrete strengths were about 4500 psi).

(b)(1), (b)(3)

Only one weapon showed any evidence of leakage. Experiments were started, using O-rings as replacements for the cork gaskets used to seal the openings in the bomb case.

It had been decided that the TX-8-X2 changes constituted a modification to the fuze rather than the bomb. Thus the Mk 8 Bomb with Mk 8 Mod 1 Fuze, incorporating a frangible nose and T-31 fuze tape control, was released for production and entered stockpile September 1953.

The TX-G Committee, whose functions had been largely assumed by the Special Weapons Development Board, was dissolved in January 1954. The Aspen Committee, which was directing Sandia-Los Alamos activities on the TX-11 weapon, agreed to handle any residual interlaboratory matters on the Mk 8 program.

(b)(3)

This change was made in the Mk 8 Mod 2 Bomb which was stockpiled in May 1955.

Meanwhile, studies had been made of the desirability of replacing the original Abner initiator with an improved design, the Phoebe. This change, plus the O-rings for sealing the bomb case, was known as the TX-8-X3 program during development.[44] Changes to the Atomic Energy Act permitted the Military to produce and stockpile certain atomic weapons parts, and it was suggested that the Bureau of Ordnance assume control of TX-8-X3 production work.[45] This proposal was rejected by the Atomic Energy Commission, which felt that close phasing was required, due to changes to both nuclear and nonnuclear portions of the Mk 8, and that Sandia should retain production control.[46] The Mk 8 Mod 3 was stockpiled in October 1955.

By February 1957, the Mk 11 Bomb was in production and entering stockpile. A decision was made to retire the Mk 8 weapons on a one-for-one basis as Mk 11's entered War Reserve. This retirement program started May 1957 and was completed 2 months later.

Mk 8 Warhead

The first consideration of a gun-type device for use with guided missiles was in a Los Alamos meeting of early March 1950, in which various missile programs were discussed.[47] Little immediate action was taken and, during the summer of that year,

attention was concentrated on developing the Elsie as a free-fall bomb to be released from aircraft. However, September 13, 1950, Santa Fe Operations Office requested Sandia and Los Alamos to consider the application of a penetrating warhead to various guided missiles. The missiles suggested were the HERMES A-3, HERMES C-1, REGULUS, RIGEL, and TRITON.[48]

It was obvious that a gun-type warhead would be more impact-resistant than an implosion design, and the request was referred to the Bureau of Ordnance, then doing work on the Mk 8 Bomb.

(b)(1), (b)(3)

Any missile usage would involve higher impact velocities and require new tests and additional design effort.[49] The Division of Military Application then referred the project to the Sandia Weapons Development Board, requesting that any Mk 8 Warhead developed be compatible with the above five missiles.[50]

Sandia made a preliminary study and, December 20, 1950, reported to the Santa Fe Operations Office that a firm estimate of the magnitude of the program could not be made. The terminal velocities of the missiles cited had not been definitely fixed, but were believed to be significantly greater than any previously considered in atomic-bomb design. Sandia proposed that a general investigation of impact warheads be continued, in an effort to delineate the most universally useful type of warhead and to outline a development program.[51]

The Santa Fe Operations Office suggested that initial application of the penetrating warhead be made to the REGULUS missile. This missile, scheduled for production in 1953, had a comparatively low impact velocity, and it was felt that a suitable warhead might be created by relatively simple modifications of existing components.[52] Sandia reported, January 23, 1951, that the development of such a warhead appeared feasible, and that the Bureau of Ordnance had been requested to investigate the effects of impact velocities and warhead mounting methods on the penetration characteristics of the Mk 8 device.[53]

The XW-8/REGULUS was authorized for design activity by the Santa Fe Operations Office February 14, 1951.[54] It was noted that since the REGULUS would attain an

SECRET
RESTRICTED DATA

impact velocity of only Mach 1.2, there would be few shock problems, unless the weapon were employed against extremely hard targets such as igneous rock or heavy armor plate.[55]

It was determined that the fuzing accuracy for the XW-8/REGULUS could be less than for an air-burst device, since the only requirement was to initiate a pyrotechnic delay train about one minute prior to impact. Should the weapon be launched from a submarine, a simple arming system would protect the submarine against premature detonations.

The Sandia Weapons Development Board discussed the Mk 8 missile-warhead program in its April 10, 1951 meeting. It was felt that current weapon capabilities would not allow impact velocities higher than Mach 2.5 without danger of breakup of the device. Since the terminal velocity of the HERMES was estimated to be Mach 4.5, it was obvious that radical changes to either warhead or missile would have to be made if this missile were used. It was apparent that either approach would require much design investigation, and it was decided to consider only the XW-8/REGULUS.[56]

It was found that the warhead compartment of the REGULUS was long enough to hold the basic Mk 8 Bomb assembly, but that little excess clearance was available, and that access to the nose of the weapon was difficult. Additionally, the center of gravity of the missile would be about 30 inches forward of its optimum location, and it was decided to delete the afterbody of the Mk 8. Tests were started to determine the terraballistics of the Mk 8 without its afterbody, and to ascertain whether the warhead would break away from the missile on impact with various surfaces.[57]

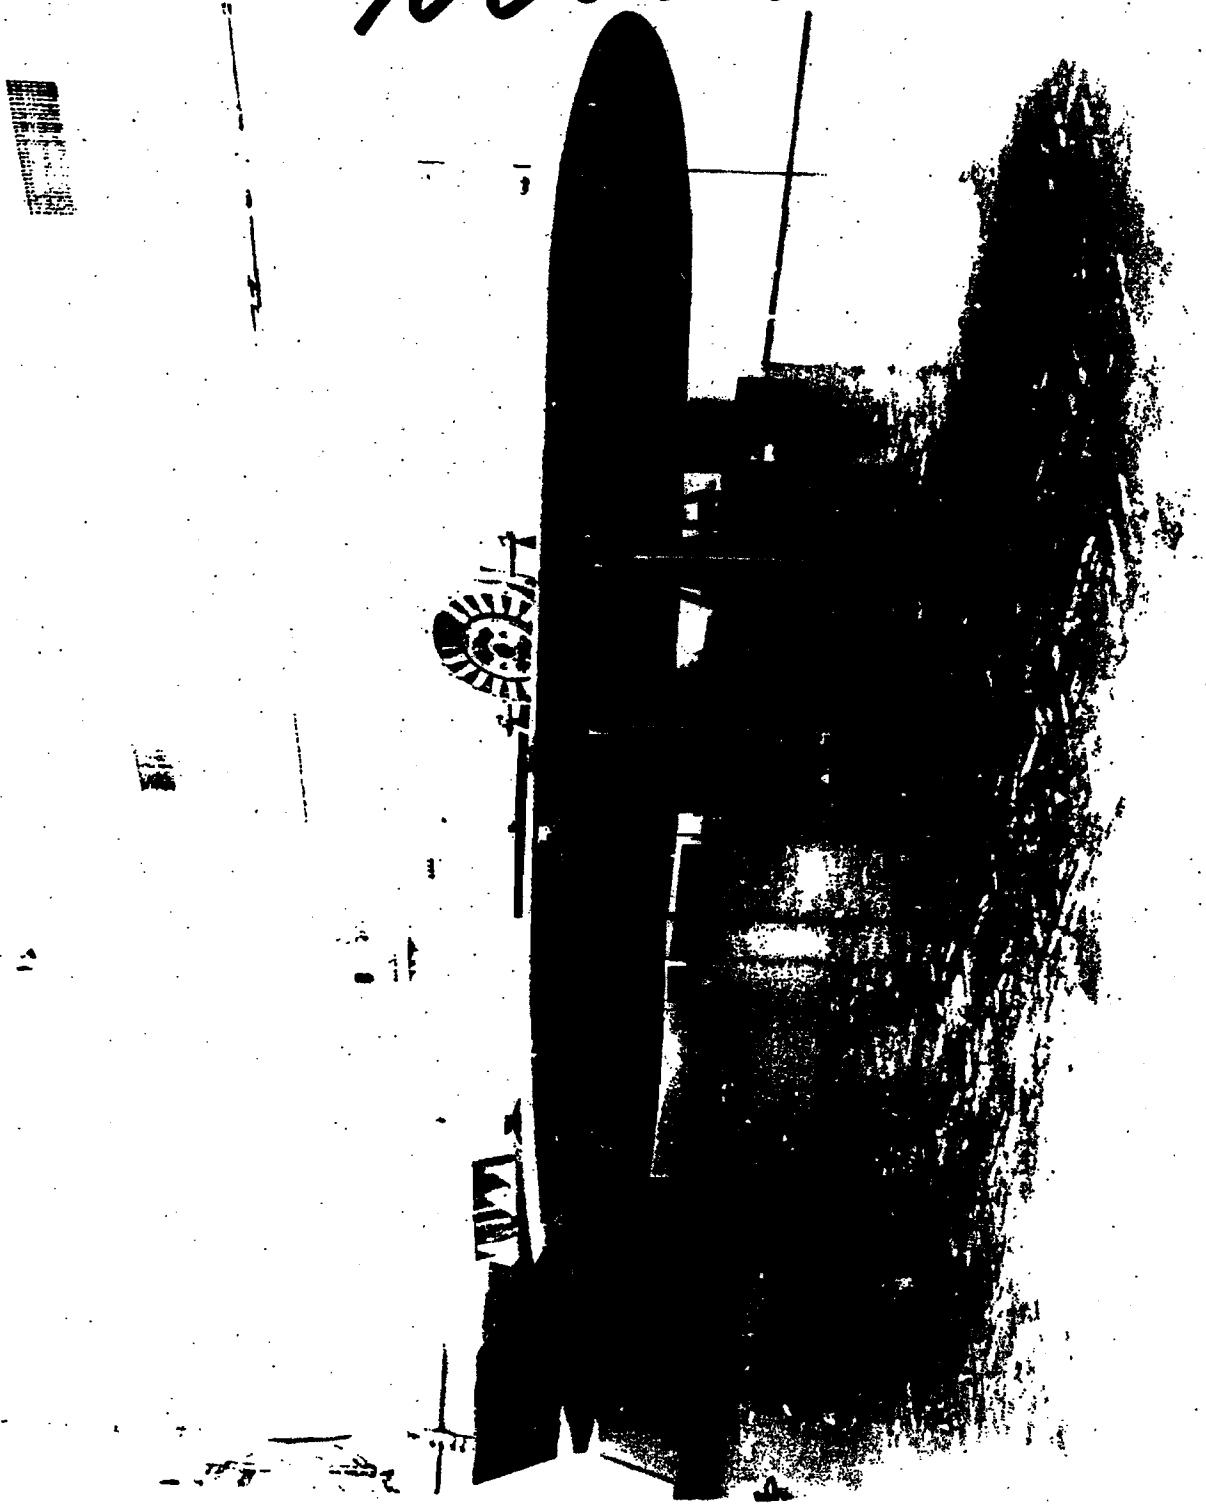
Another problem was the development of a mechanism to ignite the propellant of the internal gun device of the XW-8/REGULUS. In the drop bomb, this was accomplished by arming tapes, but the warhead application required either a device to pull the tapes at the proper point in the missile trajectory or a modification of the fuze.

yield would be the same as that of the Mk 8 Bomb. The warhead would function properly when subjected to missile impact speeds up to Mach 1.1 on water, earth, reinforced concrete and, if possible, harder targets. It would not broach or ricochet after impacts at angles between 60 and 90 degrees. The weapon would penetrate the target and detonate after coming to rest, and would be sufficiently watertight to function after water impact, followed by bottom impact.[64]

The Military Liaison Committee notified the Division of Military Application, October 3, 1952, that no requirement existed for design of penetration warheads capable of impact velocities higher than those of the REGULUS missile.[65]

Meanwhile, the Military decided that efficient use of the XW-8/REGULUS weapon required a high delivery accuracy. This was not possible with the existing missile system, and production requirements were deferred, awaiting refinement of the missile guidance system. Sandia was requested to complete its design work on the warhead, and the Navy was asked to proceed with scheduled flight tests.[66]

Successful component evaluation flights were conducted, and a successful warhead system test was held September 24, 1953. The Military Liaison Committee then suggested that, since there were few differences between the XW-8 Warhead and the extensively tested Mk 8 Bomb, further systems tests be held in abeyance.[67]



Design of the missile-warhead was completed in August 1954, and Report SC3483(TR), Status and Evaluation of the XW-8/REGULUS Warhead Installation at Design Release, was presented to the December 1, 1954 meeting of the Special Weapons Development Board.[68] The warhead was named the Mk 8 Mod 2, and production responsibility assigned to the Bureau of Ordnance.

The warhead contained three delay fuzes, two located on the side and one on the nose. (b)(3)

All requirements of the military characteristics were satisfied by the test program, although impact tests at less than 90 degrees were not conducted, and it was

not definitely determined whether the warhead would penetrate the target or break away on impact. However, Mk 8 Bomb tests had shown that satisfactory penetrations were achieved at entry angles as low as 30 degrees to the surface, and it was felt that the warhead would have similar satisfactory characteristics.

Subsequently, the possibility of developing a guidance system to effectively deliver the XW-8/REGULUS with pinpoint accuracy appeared remote. Consequently, on May 20, 1955, the Navy suspended activity in the program, together with work on the XW-11/REGULUS application.[69]

TX-10 External View

Subsequently, the Division of Military Application proposed that a lightweight, air-burst, gun-type missile warhead be developed,[74] and this suggestion received the backing of the Military Liaison Committee July 6, 1950.[75] It was proposed that Army Ordnance, then involved with the Mk 9 Shell, be requested to assist in design and development.[76]

Meanwhile, the lightweight, air-burst, gun-type bomb project had not been entirely forgotten, and the Military Liaison Committee, in a letter dated August 9, 1950, stated that the Joint Chiefs of Staff had established a requirement for the development of air-burst bombs sufficiently light in weight and small in cross section to be carried by high-speed tactical airplanes of the Air Force and Navy. It was felt that these bombs could be based on either implosion- or gun-type nuclear devices, and formal requests were made for both types.[77]

The subject was discussed in the August 16, 1950 meeting of the Sandia Weapons Development Board, with the Board agreeing to assume cognizance of the project. Two problems were immediately apparent: The development of a flexible fuzing system capable of attacking various tactical targets, and a weapon resistant to temperatures as low as -100°F.[78]

Sandia had meanwhile made a study of a lightweight bomb design and reported to AEC-Sandia August 17, 1950, that this could be produced by mid-1952. It was suggested that North American Aviation, Inc., be assigned the task of developing and manufacturing the outer case, internal support structures, and parts of the carrying pylon. Sandia would develop a fuzing and firing system, conduct drop tests, provide test and handling equipment, and act as project coordinator.[79]

On the same date, the Division of Military Application forwarded military characteristics for the above bomb. These required that the bomb be capable of tactical use by fighter, light bombardment, and attack (dive bomber) aircraft. The primary requirement was for external carriage, with alternate internal carriage being desired.

(b)(1), (b)(3)

The TX-G or Gun Committee agreed to accept interlaboratory responsibility for the TX-10.[26] The program was subjected to an intensive review in a Committee meeting of December 14, 1950, with the TX-10 being compared with the TX-7, an implosion design that had been pushed rapidly and which was now scheduled to enter stockpile earlier than the TX-10. It was felt by some conferees that the basic need for the TX-10 was eliminated by the advent of the TX-7. This latter weapon was larger than the proposed diameter of the TX-10 (27 inches versus 17 inches), but there appeared to be a sufficient variety of airplanes that could carry the TX-7.

(b)(1), (b)(3)

The problem was referred to the Sandia Weapons Development Board and discussed in a meeting December 20, 1950, with the Board being furnished copies of Sandia Report SC-1684(TR), A Critical Comparison Between the TX-7 and TX-10 Programs. This report noted that design was in work on a follow-on (and smaller) implosion device for the TX-7 (to be called the TX-12). The TX-12 would be less costly from the nuclear standpoint, would offer greater chances of increasing nuclear efficiency, and could be developed in about the same time scales. It was pointed out that work on the TX-10 would subtract effort from the TX-12, and that tactical use of the TX-10 (if manufactured in large numbers) would require major realignment of component production.

The Board noted that the TX-10 diameter would probably be smaller than the TX-7 or TX-12, but stated that further reductions in implosion-weapon diameter could be expected, as much nuclear design effort was currently being placed on implosion design improvements. After extensive discussion, the Board recommended that the TX-10 development be dropped in favor of the TX-12.[89]

The Division of Military Application wrote to Santa Fe Operations Office January 3, 1951, making reference to the above meeting. There were hopes that an interim TX-10 could be made available earlier than the TX-12, and it was suggested that the requirement for nuclear safing be eliminated and an external shape suitable for subsonic (but not necessarily supersonic) carriage be provided.[90]

The design status of the TX-10 was reviewed in the April 10, 1951 meeting of the Sandia Weapons Development Board. The bomb would be at least 17 inches in diameter and 2000 pounds in weight.

(b)(3), (b)(1)

The Board noted that the diameter and weight of the TX-10 exceeded the military characteristics, and that major reductions in these items could not be expected until the nuclear gun design was revised by Los Alamos.

(b)(3)

The project thus reverted to fundamental study of the problems of providing low burst heights, miniaturization, supersonic aerodynamics, and nuclear design improvements. Subsequently, the Military Liaison Committee canceled the TX-10 Bomb program May 7, 1952, noting that the Joint Chiefs of Staff had stated that a military requirement for the weapon no longer existed.

(b)(3)

SECRET
RESTRICTED DATA

Mk 11 Weapon

The Mk 11 Bomb, a gun-type penetrating weapon to be externally carried on high-speed aircraft, had its early beginnings when the gun-type device was considered for guided-missile application in March 1950. In this usage nuclear safing would be required to protect the missile launching site, and it would be necessary for the warhead to survive high impact velocities.[47]

Subsequently, the Division of Military Application expressed interest in a gun-type bomb that could be nuclearly safed and externally carried on high-speed aircraft.[99] The external shape of the Mk 8 did not lend itself to such carriage (due chiefly to its blunt nose), and it was felt that any modification of the nose shape would be complicated by the existence of the nose fuze. A nose redesign would require a lengthy effort, and it was suggested that a development program be authorized for a Mk II Elsie for such usage.[100]

The Military Liaison Committee released a set of desired military and technical characteristics for impact, delayed-action atomic bombs April 17, 1950. These characteristics described a bomb which could be nuclearly safed during aircraft carriage and that would be suitable for release at speeds up to Mach 1.2.[54] Subsequently, July 31, 1950, the Division of Military Application requested the Bureau of Ordnance to design a Mk 8-type weapon meeting these characteristics, and offered Sandia assistance in the task of fitting the design to appropriate carrying aircraft.[101] This proposal was accepted by the Bureau of Ordnance,[102] and nomenclature of TX-11 was assigned to the project November 29, 1950.[103]

There were three main gun-weapon problems being studied at this time: The ballistics problem relating to external carriage and release at high speeds; the nuclear safing problem, which concerned missiles as well as bombs; and the problem of increasing the resistance of the weapon to impacts on hard targets, such as reinforced concrete, rock and armor plate.

The Naval Ordnance Laboratory started to design the TX-11 fuzing system. It was felt that feasibility and preliminary design studies to establish tentative characteristics could be completed by January 1, 1952; and that detailed design

toss, glide and dive bombing. It would be capable of carriage and release at speeds up to Mach 1.4 and altitudes of 50,000 feet. It would be able to function satisfactorily after impacts on water, soil, reinforced concrete, and--to the extent practicable--harder targets.

The Board noted that the characteristics required external carriage at both subsonic and supersonic speeds, but a shape designed for one of these velocities would not be optimum for the other. It was felt that the design should be based on the assumption that the least drag during the major portion of the flight was desirable. Inasmuch as jet fighters en route to a target cruised at subsonic speeds, the bomb shape should be designed to meet this requirement.

The desire that the weapon be capable of penetration into hard rock was of concern. It was difficult to suitably define "hard rock," and there was felt to be a low incidence of this type of terrain near any probable targets. The scheduled design-release date was established as October 1953, with the bomb to enter stockpile in January 1955.[34]

The Bureau of Ordnance had been conducting tests of a soft-steel nose cap which, it was hoped, would crush and absorb the shock of weapon impact. These tests were not encouraging, and it was eventually decided to provide a Fiberglas nose cap. When the bomb was to be carried in an internal bomb bay, this nose cap could be removed.

Wind-tunnel tests had meanwhile narrowed the choice of weapon length to two possibilities; 146 and 169 inches. The Bureau of Ordnance recommended that the shorter figure be selected: It caused less drag at subsonic speed, it was compatible with all aircraft being considered for carriage of the bomb, and it could be carried internally in all aircraft except the B-50 without removing the nose cap.[109]

Full-scale drops at Inyokern produced excellent results.

(b)(1), (b)(3)

No detonation of the high explosive occurred during any of the impacts. Tests of 6-1/4-inch-diameter scale models against reinforced concrete 10 feet thick demonstrated that impact velocities between 2000 and 2200 feet per second could be

absorbed.[110] As a result of these tests, the length of the TX-11 was frozen at 146 inches on June 30, 1952, and the fin size was established at two bomb diameters, or 28 inches.[111]

Meanwhile, work had been undertaken on the design of a nuclear safing system,

(b)(3)

The fuzes were mechanically armed and were of a pyrotechnic design similar to those used in the Mk 8.

SECRET
RESTRICTED DATA

Glossary of Terms

Ad Hoc Working Group -- A group established by the Guided Missiles Committee to oversee the design of one particular missile-warhead installation.

Armed Forces Special Weapons Project -- An interdepartmental agency formed to handle military functions related to atomic weapons.

(b)(1), (b)(3)

Contact Fuze -- A fuze that detonates the weapon by contact with the ground or target.

Crossroads -- Full-scale tests of Mk III Bombs, held at the Pacific Proving Grounds. The Bikini Baker shot was held July 25, 1946. Much effects data were gained, and the shot was so destructive that a scheduled deep underwater burst was canceled.

Division of Military Application -- An AEC office that functions as liaison between the Military and weapons designers and producers.

Drag -- Resistance created by the passage of a shape through the air.

Field Command -- The local office of the Armed Forces Special Weapons Project, located on Sandia Base, Albuquerque, New Mexico.

SECRET
RESTRICTED DATA
UNCLASSIFIED

Joint Research and Development Board -- A Board established in mid-1946 as a postwar replacement for the Office of Scientific Research and Development. Its purpose was to suggest lines of research and development on military weapons and equipment.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Little Boy -- Code name for the gun-type weapon dropped on Hiroshima, Japan, August 6, 1945, during World War II. Originally called the Thin Man in reference to its long thin shape. The Thin Man was to use plutonium-239 as its nuclear material. Early samples of this isotope revealed that it contained small amounts of plutonium-240 which had a high preinitiation rate. A decision was then made to use uranium-235, allowing the length of the weapon to be radically reduced (due to the lower speed of assembly of the critical material). This change in outer shape was given the code name of Little Boy.

Los Alamos Scientific Laboratory -- A nuclear design organization located at Los Alamos, New Mexico. Called the Los Alamos Laboratory during World War II.

Mach -- A measure of speed. Mach 1.0 is the speed of sound, or 738 miles per hour at sea level.

Manhattan Engineer District -- A District of the Army Engineers established in August 1942 to provide the facilities that would be needed for design and construction of the atomic bomb.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

A En r v t Man n t l E

s A i ro e o o y s I

Naval Ordnance Laboratory -- A portion of the Bureau of Ordnance devoted to design and test of Naval ordnance.

Neutron -- An uncharged particle of slightly greater mass than the proton.

Operation Crossroads -- See Crossroads.

Pitch -- Motion of the bomb as it falls through the air, such that the nose and tail alternately rise and fall.

Proton -- The nucleus of the atom of the light isotope of hydrogen. It has a unit positive charge of electricity.

Prototype -- An early weapon type, generally hand-produced before a production run.

Pylon -- A strut to hold bomb in position below an airplane wing.

Pyrotechnic Fuze -- A fuze that operates by burning or detonation of a small charge of explosive.

Radar -- Named for Radio Detecting and Ranging. Radars emit a pulse of high-frequency energy and measure the time lapse from that transmission to receipt of a reflected electrical "echo" from an object. This time measurement determines the distance of the object from the transmitting antenna of the radar.

Ricochet -- A glancing rebound of a missile when it strikes a target.

Safing -- Putting a weapon in condition such that it cannot fire.

Salton Sea Test Base -- Located on the site of a Naval Auxiliary Air Station on the shores of Salton Sea, California. One of the early sites for ballistic tests of atomic bombs.

Sandia Research and Development Board -- A joint Sandia-Military board formed March 2, 1948, at Sandia Base to provide local guidance on weapons design.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent of uranium-238; the rest is uranium-235.

Z Division -- A division of the Los Alamos Scientific Laboratory, elements of which moved to Sandia Base and became the nucleus of Sandia Laboratory and Corporation.

(b)(3)

History of Gun-Type Bombs and Warheads

Mk 8 Bomb

The gun method of assembling nuclear material, used in the wartime Little Boy design, was the first atomic weapon system to be devised, predating the establishment of the Los Alamos Laboratory. The method was nuclearly inefficient and was largely ignored for a time after the end of World War II, while interest centered on implosion techniques.

(b)(1), (b)(3)

At this time, the Los Alamos Scientific Laboratory was fully occupied in the above-mentioned study of improvements in implosion devices, and suggested that the task of developing a water-penetrating weapon (which probably would use gun techniques) could best be accomplished by a military group. No immediate action was taken on this suggestion, but the subject was briefly examined by the Z Division of Los Alamos in late 1946 and early 1947.

(b)(1), (b)(3)

The topic was subsequently discussed in a meeting of the Weapons Subcommittee of the AEC General Advisory Committee, and a decision made May 15, 1947 that consideration of a penetrating weapon be postponed.[4]

Meanwhile, however, the Military Liaison Committee had been discussing the general subject of subsurface atomic weapons. At the instigation of the Navy member, Rear Admiral William S. Parsons (who had armed the wartime gun-type Little Boy for

its historic drop on Hiroshima), Section ReM of the Navy's Bureau of Ordnance, prepared preliminary sketches of a penetrating gun device.

At about the same time, other groups were considering the same subject. The Joint Research and Development Board had established a Committee on Atomic Energy, and the subject of penetrating weapons was discussed in the October 2, 1947 meeting of this Committee. It was urged that serious consideration be given to the development of a gun-type device suitable for penetration use. Since the AEC weapon laboratories were already fully occupied with other high-priority work, the Committee recommended that the facilities of the Bureau of Ordnance be used.[5]

The Division of Military Application had also been considering the advisability of invoking the assistance of the military services in the development of penetrating weapons. Los Alamos had noted that gun systems were inherently inefficient, and expressed an opinion that the weapons laboratories should continue to concentrate on design of implosion devices.[6] Thus the Military Liaison Committee was requested to assign mechanical design of a gun-type penetration weapon to the Bureau of Ordnance.[7]

These several requests, all in the same vein, were presented for consideration to the Military Liaison Committee which, April 9, 1948, requested the Atomic Energy Commission to undertake development of a penetrating-type weapon, using the facilities of the Bureau of Ordnance.[8] This request was formally presented to the Bureau April 27, 1948, and accepted.[9] A code name of "Minnie" was initially assigned to the project, but was later found to have been used for a Bureau of Ships propulsion project and, in mid-July 1948, the name was changed to "LC" (a follow-on term to "LB," for the Little Boy), and which came to be commonly written as "Elsie."[10] That the Elsie program was considered a matter of some interest to the Military was indicated in a May 6, 1948 meeting of the Sandia Research and Development Board in which the project was assigned top priority, second only to the schedule for getting the Mk 4 Bomb into full-scale production.

The Bureau of Ordnance issued detailed work assignments. The Naval Ordnance Laboratory would be responsible for developing suitable pyrotechnic delay fuzes.

The Naval Ordnance Test Station would study external ballistics and design the tail. The Naval Powder Factory would investigate powder development. The Naval Ordnance Plant would handle much of the manufacturing and testing program, and when this location was subsequently closed, the work would be transferred to the Naval Proving Grounds and the Naval Gun Factory. Section ReM of the Bureau of Ordnance would provide overall design controls, including the task of guaranteeing survival of the nuclear assembly under impact conditions.

The development program would proceed in three overlapping phases. Feasibility and preliminary design studies would outline the most promising general design characteristics of the weapon, and these were scheduled for completion January 1, 1949. The second phase, covering experimental development and testing of prototype weapon design, would be completed a year later. The third phase, manufacture of prototype weapons, would be finished in another year, or January 1, 1951.

(b)(3)

The studies advanced rapidly and, by September 3, 1948, the Bureau of Ordnance could report that the design appeared feasible and that a weapon could probably be devised that would function satisfactorily after impact on water, and possibly after impact on hard surfaces which the weapon might encounter beneath the surface of the water.[11] It was initially felt that the fuze should be actuated at impact and have a delay of 1 to 2 minutes before bomb detonation, but it was later decided that a more reliable bomb would be created if the fuze action were initiated at time of release of the bomb from the carrying aircraft.

The diameter of the bomb would be about 14 inches and the weight would be about 3000 pounds, as compared to 28 inches and 8900 pounds for the Little Boy. These reductions were due to the more compact nuclear assembly and a decrease in the thickness of the bomb case. The shape would be roughly cylindrical, with a flat nose for good penetration characteristics, and the bomb would attain a maximum impact velocity of 1500 feet per second. The minimum release altitude would be 500 feet, to give the bomb enough time during its fall to assume proper entry attitude, and there would be no restriction on maximum release altitude. It was felt that three separate and independent fuzes should be used, to provide adequate relisbility. A meeting was held October 25 and 26, 1948, with Los Alamos assuming the task of developing impact-resistant initiators.[12]

An extensive series of tests was performed. The first group included 174 half-scale bombs of 6.25-inch diameter. These were fabricated in 49 different configurations, and were impacted against targets of steel and concrete at different angles, striking velocities, and missile temperatures ranging from -65°F to +165°F.

(b)(3)

Following the above, some 38 full-scale impact tests were conducted, to confirm the half-scale results. Interior ballistic tests were performed, to check the burning rate of various propellants and the behavior of the missile in the gun barrel. As fuze components became available, they were subjected to the shock produced by firing from a 14.25-inch-diameter railway gun.

Two series of wind-tunnel tests were held, one at the University of Minnesota to obtain aerodynamic coefficients of various tail configurations, and the other at the California Institute of Technology Cooperative Wind Tunnel to evaluate aerodynamic characteristics of five basic designs.

directive was issued August 30, 1950, accompanied by a request that the facilities of the Bureau of Ordnance be used to the fullest extent possible.[17] At this time, the Elsie was assigned nomenclature of TX-8.[18]

An intensive study had been undertaken of changes required to allow external carriage of the TX-8. There were several reasons why these changes were necessary. For one, the fuze system had been designed to operate under protected bomb-bay conditions. For another, the shape of the TX-8, with its blunt nose, caused excessive drag, especially at high speeds.

(b)(3)

It was obvious that this would require considerable study, and it was suggested that the Bureau of Ordnance establish a parallel program for the development of a Mk II Elsie suitable for either internal or external suspension, while work continued on an internally carried TX-8.[19]

The Bureau made a survey and reported that the existing shape of the TX-8 was adequate for subsonic external carriage if some minor changes were made to the tail design,[20] and the shape could be carried in the space available under the centerline of the F4U, AD and A2D airplanes. It was noted that development of a shape for external carriage at supersonic velocities would require additional study and development, and this effort would be of interest in connection with a recent proposal that an XW-8 Warhead be fitted to a guided missile. Subsequently, October 3, 1950, the Division of Military Application authorized development of an externally carried TX-8 with subsonic aircraft and development of a new bomb (the TX-11) for high-speed external carriage.[21]

Meanwhile, the Armed Forces Special Weapons Project had been drawing up a paper specifying the desired military and technical characteristics of penetrating-type weapons.

(b)(1), (b)(3)

This paper was circulated for comment to Sandia and Los Alamos as well as the Military, and was subjected to a critical review.[23] The formal issue of the characteristics on November 10, 1950, however, retained the release speed requirement and noted that the bomb should function reliably when released at any altitude up to 50,000 feet and survive impacts on water, reinforced concrete, and--hopefully--thin steel plate.

(b)(3)

The November 22, 1950 meeting of the Sandia Weapons Development Board reviewed the overall gun-type weapons program, which now included the TX-9, TX-10, and TX-11, in addition to the TX-8. It was noted that the TX-8 was composed of three main parts: The nose, the tail, and the clamping ring which joined them. The bomb diameter had been fixed at 14.5 inches, its length at 116 inches, and its weight at 3260 pounds. The nose was a heavy forging with a blunt shape for water and ground entry, and contained the internal gun barrel, tamper, and projectile.

(b)(3)

A saddle on the external top of the bomb case contained switches and electrical connections to operate the primers.[25]

Sandia had proposed that an interlaboratory gun-type weapon coordination committee be established, similar in scope and authority to the TX-5 Steering Committee. Action was taken on this suggestion in late 1950, and the first meeting of this Gun Committee, with representation from Los Alamos and Sandia, was held December 8, 1950.[26] At this time, the TX-5 Steering Committee was renamed the TX-N Steering Committee to reflect its interest in all implosion weapons, and the new Gun Committee came to be known as the TX-G Steering Committee.

The first meeting of the TX-G Committee heard a report from Los Alamos concerning progress on design of an initiator for the TX-8. The initial design had been based on the device used in the Little Boy, and was then modified as design weaknesses were uncovered by the testing program. Some idea of the problems encountered were shown by the increasing impact requirements as the design progressed. The initial

assumption had been that the highest shock encountered in ground impact would be 7500 g's. This figure had progressively increased during design and was now 100,000 to 300,000 g's.

(b)(3)

Studies were meanwhile in progress on systems for nuclear safing.

(b)(3)

In early 1951 it was decided to identify the adaptation of the TX-8 for external carriage at subsonic speeds as the TX-8' (or TX-8 Prime) program. Plans were made to make only minor changes to the TX-8 and provide early, but only partial, satisfaction of the requirements for an externally carried TX-8. It was felt that, if this program could not be accomplished within a short time, it should be canceled in favor of the TX-11 Bomb, then being designed for external carriage on high-speed aircraft.

At this time, the AD4 and the F4U5 were the only carriers specified for the TX-8'. The AD4 was selected as the test aircraft, and Sandia issued a contract through the Bureau of Aeronautics to Douglas Aircraft Company to modify this aircraft for TX-8 carriage. Douglas designed a nose cap to reduce drag and help protect the TX-8' fuzing elements.

In late October 1951, the TX-8' program was divided into two parts; the TX-8-X1 and TX-8-X2. The X1 was the basic TX-8' program; the X2 was to provide a cleaner aerodynamic design and reduce the drag caused by the saddle. Inasmuch as 20 drops had already been made with the TX-8-X1, its compatibility and reliability were felt to have been proven, and attention was concentrated on the TX-8-X2 design.[33]

The T-28 saddle functions were replaced by a small box located in the aircraft fuselage. This allowed the use of a standard two-hook bomb rack and increased the clearance between the externally carried bomb and the ground. Fairings were installed over the side fuzes to reduce drag. Fuze tapes used for safing were pulled through the nose fairing to protect them from the windstream. A quick disconnect was installed, to permit the weapon to be dropped with tapes in place, thus leaving barriers in the path between the primer and the propellant, and preventing the fuzes from firing the main propellant charge.

This new device was called the T-31, and a subcontract was issued for its development. Due to the subsequent failure of the subcontractor to achieve a satisfactory T-31, Sandia produced a design having the T-31 located inside the bomb pylon, thus making it possible to detach the arming tapes from the pylon after bomb release, and prevent aircraft damage caused by whipping of the tapes in the slipstream. This work was undertaken November 5, 1951, and satisfactory hardware was being produced 10 days later.

The Mk 8 Mod 0 weapon was initially produced in November 1951 and was stockpiled in January 1952.

(b)(1), (b)(3)

The Military Liaison Committee, in a letter dated October 20, 1952, requested that the bomb be designed to withstand storage for 6-month periods under occasional temperature extremes of -80°F to +165°F, and flight bomb-bay temperatures of -90°F. It was pointed out that external bomb carriage might experience even more rigorous conditions of -100°F during a 12-hour flight, and that the 24-hour limitation regarding weapon assembly would be operationally troublesome.[40]

Inasmuch as the propellant characteristics were specified by the Bureau of Ordnance, the problem was referred to this organization.[41] It was noted that the environmental criteria had been specified after detail design of the Mk 8 had been essentially completed, and that these criteria differed considerably from the initial Mk 8 development objectives. It was also pointed out that any project to provide a propellant with improved temperature characteristics would duplicate work being undertaken in the TX-11 program. The Bureau of Ordnance subsequently allowed relaxation of the temperature limitations to 7 days at 130°F, 60 days at 120°F, and indefinitely at 110°F.[42] On March 12, 1953, the Military Liaison Committee agreed that major redesign efforts toward relieving temperature limits be directed toward the TX-11.[43]

The possibility of water leakage into the interior of the gun nuclear system had been a matter of early concern.

(b)(1), (b)(3)

When recovered, there was only about half a cup of water in the barrel, and this leakage was not felt great. Nevertheless, the Military, in the April 16, 1952 meeting of the Sandia Weapons Development Board, requested that the possible effects of this leakage on weapon performance be studied.[38]

Consequently, drops were made on a limestone bed in southwestern New Mexico. This rock possessed extremely high compressive strengths, from 18,000 to 23,000 pounds per square inch (average concrete strengths were about 4500 psi).

(b)(1), (b)(3)

Only one weapon showed any evidence of leakage. Experiments were started, using O-rings as replacements for the cork gaskets used to seal the openings in the bomb case.

It had been decided that the TX-8-X2 changes constituted a modification to the fuze rather than the bomb. Thus the Mk 8 Bomb with Mk 8 Mod 1 Fuze, incorporating a frangible nose and T-31 fuze tape control, was released for production and entered stockpile September 1953.

The TX-G Committee, whose functions had been largely assumed by the Special Weapons Development Board, was dissolved in January 1954. The Aspen Committee, which was directing Sandia-Los Alamos activities on the TX-11 weapon, agreed to handle any residual interlaboratory matters on the Mk 8 program.

(b)(3)

This change was made in the Mk 8 Mod 2 Bomb which was stockpiled in May 1955.

Meanwhile, studies had been made of the desirability of replacing the original Abner initiator with an improved design, the Phoebe. This change, plus the O-rings for sealing the bomb case, was known as the TX-8-X3 program during development.[44] Changes to the Atomic Energy Act permitted the Military to produce and stockpile certain atomic weapons parts, and it was suggested that the Bureau of Ordnance assume control of TX-8-X3 production work.[45] This proposal was rejected by the Atomic Energy Commission, which felt that close phasing was required, due to changes to both nuclear and nonnuclear portions of the Mk 8, and that Sandia should retain production control.[46] The Mk 8 Mod 3 was stockpiled in October 1955.

By February 1957, the Mk 11 Bomb was in production and entering stockpile. A decision was made to retire the Mk 8 weapons on a one-for-one basis as Mk 11's entered War Reserve. This retirement program started May 1957 and was completed 2 months later.

Mk 8 Warhead

The first consideration of a gun-type device for use with guided missiles was in a Los Alamos meeting of early March 1950, in which various missile programs were discussed.[47] Little immediate action was taken and, during the summer of that year,

attention was concentrated on developing the Elsie as a free-fall bomb to be released from aircraft. However, September 13, 1950, Santa Fe Operations Office requested Sandia and Los Alamos to consider the application of a penetrating warhead to various guided missiles. The missiles suggested were the HERMES A-3, HERMES C-1, REGULUS, RIGEL, and TRITON.[48]

It was obvious that a gun-type warhead would be more impact-resistant than an implosion design, and the request was referred to the Bureau of Ordnance, then doing work on the Mk 8 Bomb.

(b)(1), (b)(3)

Any missile usage would involve higher impact velocities and require new tests and additional design effort.[49] The Division of Military Application then referred the project to the Sandia Weapons Development Board, requesting that any Mk 8 Warhead developed be compatible with the above five missiles.[50]

Sandia made a preliminary study and, December 20, 1950, reported to the Santa Fe Operations Office that a firm estimate of the magnitude of the program could not be made. The terminal velocities of the missiles cited had not been definitely fixed, but were believed to be significantly greater than any previously considered in atomic-bomb design. Sandia proposed that a general investigation of impact warheads be continued, in an effort to delineate the most universally useful type of warhead and to outline a development program.[51]

The Santa Fe Operations Office suggested that initial application of the penetrating warhead be made to the REGULUS missile. This missile, scheduled for production in 1953, had a comparatively low impact velocity, and it was felt that a suitable warhead might be created by relatively simple modifications of existing components.[52] Sandia reported, January 23, 1951, that the development of such a warhead appeared feasible, and that the Bureau of Ordnance had been requested to investigate the effects of impact velocities and warhead mounting methods on the penetration characteristics of the Mk 8 device.[53]

The XW-8/REGULUS was authorized for design activity by the Santa Fe Operations Office February 14, 1951.[54] It was noted that since the REGULUS would attain an

SECRET
RESTRICTED DATA

impact velocity of only Mach 1.2, there would be few shock problems, unless the weapon were employed against extremely hard targets such as igneous rock or heavy armor plate.[55]

It was determined that the fuzing accuracy for the XW-8/REGULUS could be less than for an air-burst device, since the only requirement was to initiate a pyrotechnic delay train about one minute prior to impact. Should the weapon be launched from a submarine, a simple arming system would protect the submarine against premature detonations.

The Sandia Weapons Development Board discussed the Mk 8 missile-warhead program in its April 10, 1951 meeting. It was felt that current weapon capabilities would not allow impact velocities higher than Mach 2.5 without danger of breakup of the device. Since the terminal velocity of the HERMES was estimated to be Mach 4.5, it was obvious that radical changes to either warhead or missile would have to be made if this missile were used. It was apparent that either approach would require much design investigation, and it was decided to consider only the XW-8/REGULUS.[56]

It was found that the warhead compartment of the REGULUS was long enough to hold the basic Mk 8 Bomb assembly, but that little excess clearance was available, and that access to the nose of the weapon was difficult. Additionally, the center of gravity of the missile would be about 30 inches forward of its optimum location, and it was decided to delete the afterbody of the Mk 8. Tests were started to determine the terraballistics of the Mk 8 without its afterbody, and to ascertain whether the warhead would break away from the missile on impact with various surfaces.[57]

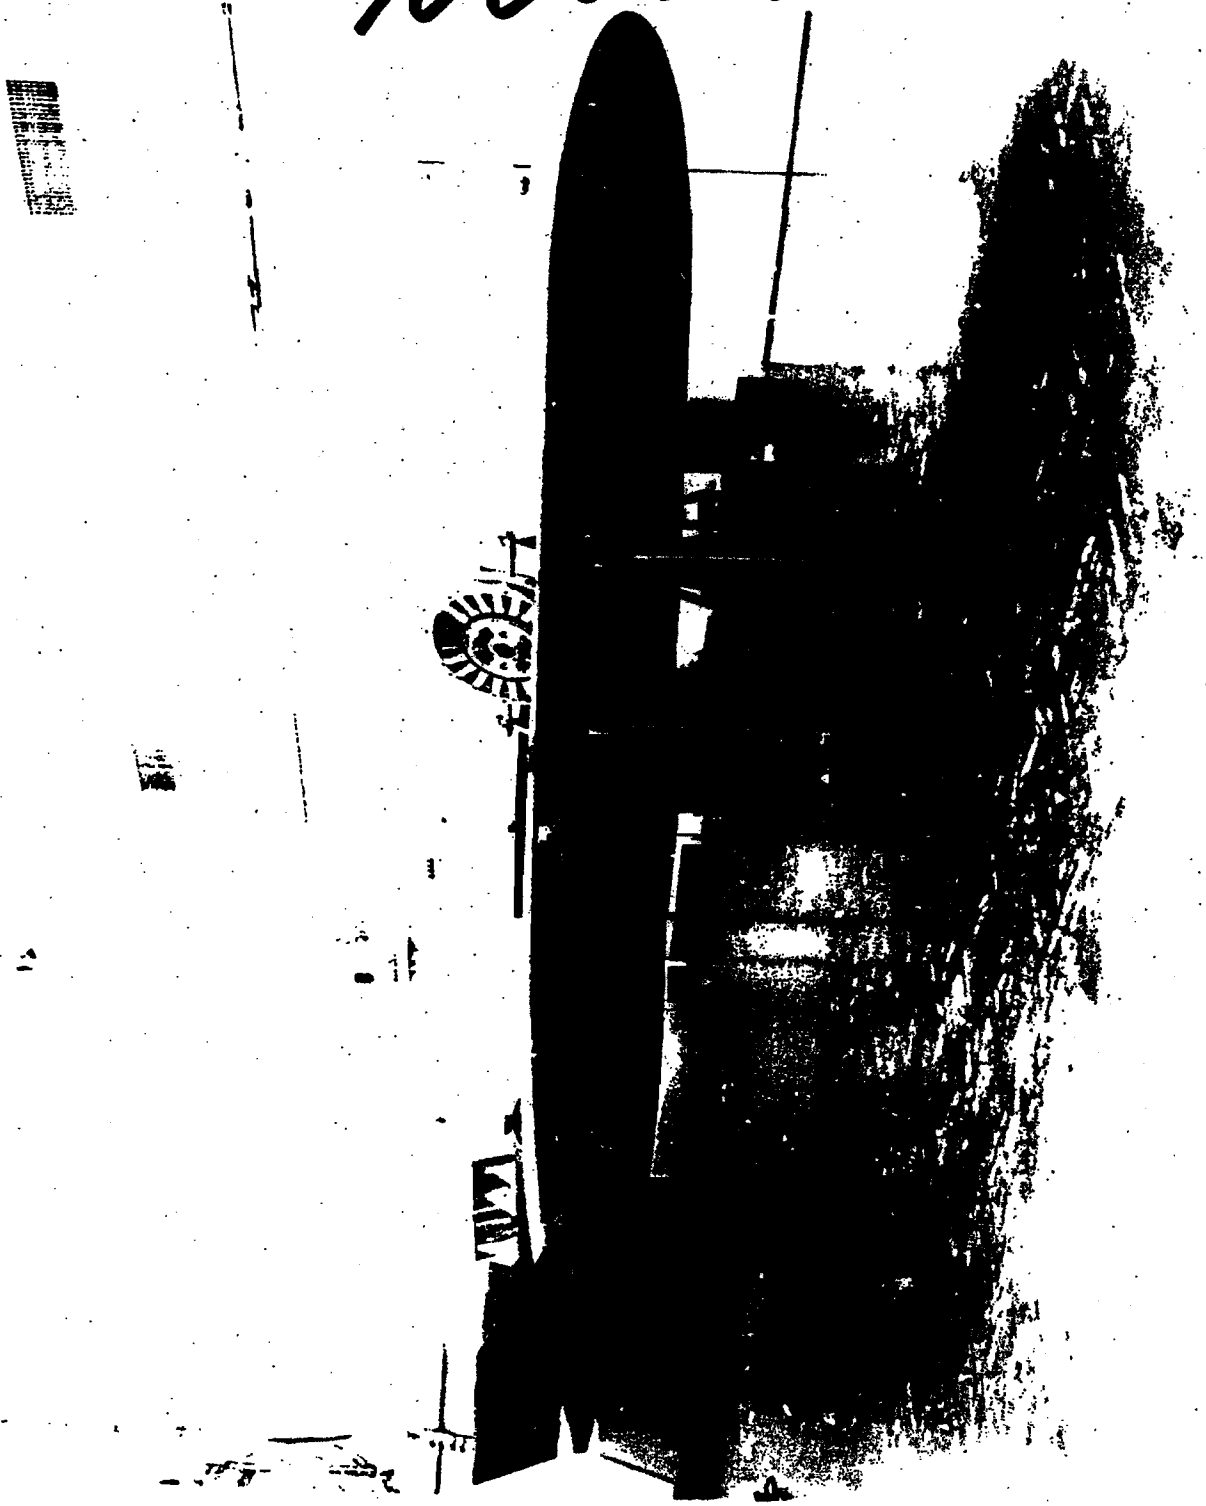
Another problem was the development of a mechanism to ignite the propellant of the internal gun device of the XW-8/REGULUS. In the drop bomb, this was accomplished by arming tapes, but the warhead application required either a device to pull the tapes at the proper point in the missile trajectory or a modification of the fuze.

yield would be the same as that of the Mk 8 Bomb. The warhead would function properly when subjected to missile impact speeds up to Mach 1.1 on water, earth, reinforced concrete and, if possible, harder targets. It would not broach or ricochet after impacts at angles between 60 and 90 degrees. The weapon would penetrate the target and detonate after coming to rest, and would be sufficiently watertight to function after water impact, followed by bottom impact.[64]

The Military Liaison Committee notified the Division of Military Application, October 3, 1952, that no requirement existed for design of penetration warheads capable of impact velocities higher than those of the REGULUS missile.[65]

Meanwhile, the Military decided that efficient use of the XW-8/REGULUS weapon required a high delivery accuracy. This was not possible with the existing missile system, and production requirements were deferred, awaiting refinement of the missile guidance system. Sandia was requested to complete its design work on the warhead, and the Navy was asked to proceed with scheduled flight tests.[66]

Successful component evaluation flights were conducted, and a successful warhead system test was held September 24, 1953. The Military Liaison Committee then suggested that, since there were few differences between the XW-8 Warhead and the extensively tested Mk 8 Bomb, further systems tests be held in abeyance.[67]



Design of the missile-warhead was completed in August 1954, and Report SC3483(TR), Status and Evaluation of the XW-8/REGULUS Warhead Installation at Design Release, was presented to the December 1, 1954 meeting of the Special Weapons Development Board.[68] The warhead was named the Mk 8 Mod 2, and production responsibility assigned to the Bureau of Ordnance.

The warhead contained three delay fuzes, two located on the side and one on the nose. (b)(3)

All requirements of the military characteristics were satisfied by the test program, although impact tests at less than 90 degrees were not conducted, and it was

not definitely determined whether the warhead would penetrate the target or break away on impact. However, Mk 8 Bomb tests had shown that satisfactory penetrations were achieved at entry angles as low as 30 degrees to the surface, and it was felt that the warhead would have similar satisfactory characteristics.

Subsequently, the possibility of developing a guidance system to effectively deliver the XW-8/REGULUS with pinpoint accuracy appeared remote. Consequently, on May 20, 1955, the Navy suspended activity in the program, together with work on the XW-11/REGULUS application.[69]

TX-10 External View

Subsequently, the Division of Military Application proposed that a lightweight, air-burst, gun-type missile warhead be developed,[74] and this suggestion received the backing of the Military Liaison Committee July 6, 1950.[75] It was proposed that Army Ordnance, then involved with the Mk 9 Shell, be requested to assist in design and development.[76]

Meanwhile, the lightweight, air-burst, gun-type bomb project had not been entirely forgotten, and the Military Liaison Committee, in a letter dated August 9, 1950, stated that the Joint Chiefs of Staff had established a requirement for the development of air-burst bombs sufficiently light in weight and small in cross section to be carried by high-speed tactical airplanes of the Air Force and Navy. It was felt that these bombs could be based on either implosion- or gun-type nuclear devices, and formal requests were made for both types.[77]

The subject was discussed in the August 16, 1950 meeting of the Sandia Weapons Development Board, with the Board agreeing to assume cognizance of the project. Two problems were immediately apparent: The development of a flexible fuzing system capable of attacking various tactical targets, and a weapon resistant to temperatures as low as -100°F.[78]

Sandia had meanwhile made a study of a lightweight bomb design and reported to AEC-Sandia August 17, 1950, that this could be produced by mid-1952. It was suggested that North American Aviation, Inc., be assigned the task of developing and manufacturing the outer case, internal support structures, and parts of the carrying pylon. Sandia would develop a fuzing and firing system, conduct drop tests, provide test and handling equipment, and act as project coordinator.[79]

On the same date, the Division of Military Application forwarded military characteristics for the above bomb. These required that the bomb be capable of tactical use by fighter, light bombardment, and attack (dive bomber) aircraft. The primary requirement was for external carriage, with alternate internal carriage being desired.

(b)(1), (b)(3)

The TX-G or Gun Committee agreed to accept interlaboratory responsibility for the TX-10.[26] The program was subjected to an intensive review in a Committee meeting of December 14, 1950, with the TX-10 being compared with the TX-7, an implosion design that had been pushed rapidly and which was now scheduled to enter stockpile earlier than the TX-10. It was felt by some conferees that the basic need for the TX-10 was eliminated by the advent of the TX-7. This latter weapon was larger than the proposed diameter of the TX-10 (27 inches versus 17 inches), but there appeared to be a sufficient variety of airplanes that could carry the TX-7.

(b)(1), (b)(3)

The problem was referred to the Sandia Weapons Development Board and discussed in a meeting December 20, 1950, with the Board being furnished copies of Sandia Report SC-1684(TR), A Critical Comparison Between the TX-7 and TX-10 Programs. This report noted that design was in work on a follow-on (and smaller) implosion device for the TX-7 (to be called the TX-12). The TX-12 would be less costly from the nuclear standpoint, would offer greater chances of increasing nuclear efficiency, and could be developed in about the same time scales. It was pointed out that work on the TX-10 would subtract effort from the TX-12, and that tactical use of the TX-10 (if manufactured in large numbers) would require major realignment of component production.

The Board noted that the TX-10 diameter would probably be smaller than the TX-7 or TX-12, but stated that further reductions in implosion-weapon diameter could be expected, as much nuclear design effort was currently being placed on implosion design improvements. After extensive discussion, the Board recommended that the TX-10 development be dropped in favor of the TX-12.[89]

The Division of Military Application wrote to Santa Fe Operations Office January 3, 1951, making reference to the above meeting. There were hopes that an interim TX-10 could be made available earlier than the TX-12, and it was suggested that the requirement for nuclear safing be eliminated and an external shape suitable for subsonic (but not necessarily supersonic) carriage be provided.[90]

The design status of the TX-10 was reviewed in the April 10, 1951 meeting of the Sandia Weapons Development Board. The bomb would be at least 17 inches in diameter and 2000 pounds in weight.

(b)(3), (b)(1)

The Board noted that the diameter and weight of the TX-10 exceeded the military characteristics, and that major reductions in these items could not be expected until the nuclear gun design was revised by Los Alamos.

(b)(3)

The project thus reverted to fundamental study of the problems of providing low burst heights, miniaturization, supersonic aerodynamics, and nuclear design improvements. Subsequently, the Military Liaison Committee canceled the TX-10 Bomb program May 7, 1952, noting that the Joint Chiefs of Staff had stated that a military requirement for the weapon no longer existed.

RESTRICTED DATA

Mk 11 Weapon

The Mk 11 Bomb, a gun-type penetrating weapon to be externally carried on high-speed aircraft, had its early beginnings when the gun-type device was considered for guided-missile application in March 1950. In this usage nuclear safing would be required to protect the missile launching site, and it would be necessary for the warhead to survive high impact velocities.[47]

Subsequently, the Division of Military Application expressed interest in a gun-type bomb that could be nuclearly safed and externally carried on high-speed aircraft.[99] The external shape of the Mk 8 did not lend itself to such carriage (due chiefly to its blunt nose), and it was felt that any modification of the nose shape would be complicated by the existence of the nose fuze. A nose redesign would require a lengthy effort, and it was suggested that a development program be authorized for a Mk II Elsie for such usage.[100]

The Military Liaison Committee released a set of desired military and technical characteristics for impact, delayed-action atomic bombs April 17, 1950. These characteristics described a bomb which could be nuclearly safed during aircraft carriage and that would be suitable for release at speeds up to Mach 1.2.[54] Subsequently, July 31, 1950, the Division of Military Application requested the Bureau of Ordnance to design a Mk 8-type weapon meeting these characteristics, and offered Sandia assistance in the task of fitting the design to appropriate carrying aircraft.[101] This proposal was accepted by the Bureau of Ordnance,[102] and nomenclature of TX-11 was assigned to the project November 29, 1950.[103]

There were three main gun-weapon problems being studied at this time: The ballistics problem relating to external carriage and release at high speeds; the nuclear safing problem, which concerned missiles as well as bombs; and the problem of increasing the resistance of the weapon to impacts on hard targets, such as reinforced concrete, rock and armor plate.

The Naval Ordnance Laboratory started to design the TX-11 fuzing system. It was felt that feasibility and preliminary design studies to establish tentative characteristics could be completed by January 1, 1952; and that detailed design

toss, glide and dive bombing. It would be capable of carriage and release at speeds up to Mach 1.4 and altitudes of 50,000 feet. It would be able to function satisfactorily after impacts on water, soil, reinforced concrete, and--to the extent practicable--harder targets.

The Board noted that the characteristics required external carriage at both subsonic and supersonic speeds, but a shape designed for one of these velocities would not be optimum for the other. It was felt that the design should be based on the assumption that the least drag during the major portion of the flight was desirable. Inasmuch as jet fighters en route to a target cruised at subsonic speeds, the bomb shape should be designed to meet this requirement.

The desire that the weapon be capable of penetration into hard rock was of concern. It was difficult to suitably define "hard rock," and there was felt to be a low incidence of this type of terrain near any probable targets. The scheduled design-release date was established as October 1953, with the bomb to enter stockpile in January 1955.[34]

The Bureau of Ordnance had been conducting tests of a soft-steel nose cap which, it was hoped, would crush and absorb the shock of weapon impact. These tests were not encouraging, and it was eventually decided to provide a Fiberglas nose cap. When the bomb was to be carried in an internal bomb bay, this nose cap could be removed.

Wind-tunnel tests had meanwhile narrowed the choice of weapon length to two possibilities; 146 and 169 inches. The Bureau of Ordnance recommended that the shorter figure be selected: It caused less drag at subsonic speed, it was compatible with all aircraft being considered for carriage of the bomb, and it could be carried internally in all aircraft except the B-50 without removing the nose cap.[109]

Full-scale drops at Inyokern produced excellent results.

(b)(1), (b)(3)

No detonation of the high explosive occurred during any of the impacts. Tests of 6-1/4-inch-diameter scale models against reinforced concrete 10 feet thick demonstrated that impact velocities between 2000 and 2200 feet per second could be

absorbed.[110] As a result of these tests, the length of the TX-11 was frozen at 146 inches on June 30, 1952, and the fin size was established at two bomb diameters, or 28 inches.[111]

Meanwhile, work had been undertaken on the design of a nuclear safing system,

Glossary of Terms

Ad Hoc Working Group -- A group established by the Guided Missiles Committee to oversee the design of one particular missile-warhead installation.

Armed Forces Special Weapons Project -- An interdepartmental agency formed to handle military functions related to atomic weapons.

(b)(1), (b)(3)

Contact Fuze -- A fuze that detonates the weapon by contact with the ground or target.

Crossroads -- Full-scale tests of Mk III Bombs, held at the Pacific Proving Grounds. The Bikini Baker shot was held July 25, 1946. Much effects data were gained, and the shot was so destructive that a scheduled deep underwater burst was canceled.

Division of Military Application -- An AEC office that functions as liaison between the Military and weapons designers and producers.

Drag -- Resistance created by the passage of a shape through the air.

Field Command -- The local office of the Armed Forces Special Weapons Project, located on Sandia Base, Albuquerque, New Mexico.

SECRET
RESTRICTED DATA
UNCLASSIFIED

Joint Research and Development Board -- A Board established in mid-1946 as a postwar replacement for the Office of Scientific Research and Development. Its purpose was to suggest lines of research and development on military weapons and equipment.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Little Boy -- Code name for the gun-type weapon dropped on Hiroshima, Japan, August 6, 1945, during World War II. Originally called the Thin Man in reference to its long thin shape. The Thin Man was to use plutonium-239 as its nuclear material. Early samples of this isotope revealed that it contained small amounts of plutonium-240 which had a high preinitiation rate. A decision was then made to use uranium-235, allowing the length of the weapon to be radically reduced (due to the lower speed of assembly of the critical material). This change in outer shape was given the code name of Little Boy.

Los Alamos Scientific Laboratory -- A nuclear design organization located at Los Alamos, New Mexico. Called the Los Alamos Laboratory during World War II.

Mach -- A measure of speed. Mach 1.0 is the speed of sound, or 738 miles per hour at sea level.

Manhattan Engineer District -- A District of the Army Engineers established in August 1942 to provide the facilities that would be needed for design and construction of the atomic bomb.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

Mk 12 Warhead

2/1/51	Military Liaison Committee notifies the Division of Military Application that the Air Force is contracting for Bureau of Ordnance development of an air-launched, free-flight rocket.
4/10/51	(b)(3)
6/5/51	Santa Fe Operations Office assigns nomenclature of XW-12.
7/13/51	TX-N Committee urges that XW-12 Warhead be assigned a high development priority.
10/29/52	Military Liaison Committee requests the Division of Military Application to undertake a preliminary investigation of an air-defense warhead.
11/14/52	Division of Military Application suggests that the study of an air-defense warhead include application to TALOS missile.
2/10/53	Military Liaison Committee notes that the Joint Chiefs of Staff have established a requirement for development of surface-to-air missiles with atomic warheads, with particular reference to the TALOS missile.
5/15/53	Field Command proposes set of military characterisitcs for a 22-inch-diameter air-defense warhead.

6/23/53	Bureau of Ordnance notes that XW-12/TALOS-W warhead installation cannot meet all the requirements for the air-defense warhead.
10/6/53	Armed Forces Special Weapons Project requests that XW-12 Warhead use as many Mk 12 Bomb components as possible, in order to expedite the development work.
1/18/54	Field Command requests Sandia to continue study of warheads capable of operation at high altitudes.
10/11/54	Field Command requests Sandia to delay Joint Task Group activities on the XW-12/TALOS-W, due to unavailability of missiles.
12/14/54	Proposal made that the XW-30 Warhead replace the XW-12.
11/21/55	XW-12/TALOS-W project terminated in favor of use of XW-30 Warhead.

History of the Mk 12 Weapon

Mk 12 Bomb

One of the military aims in the early development of atomic weapons was that of reducing the size and weight of the implosion bomb. Much progress had been made toward this end in the Mk 5 and Mk 7 programs, and, subsequently, the Los Alamos Scientific Laboratory continued intensive study in this area.

(b)(3)

This request was accordingly integrated into the 1951 Los Alamos program.[2]

(b)(3)

The desired military characteristics were forwarded by the Military Liaison Committee to the Division of Military Application March 6, 1951.[4] These called for an implosion weapon smaller than the TX-7 and established a maximum weight of 1200 pounds for the bomb. It was requested that the

Sandia presented a draft report of the proposed ordnance characteristics of the TX-12 to the October 12, 1951 meeting of the Sandia Weapons Development Board. The box dimensions of the tail fins had been established at 30 inches. A duplicate set of batteries would be incorporated to increase weapon reliability.

(b)(1), (b)(3)

The subject was discussed in the November 7 and December 11, 1951, meetings of the Sandia Weapons Development Board.[17,18] It was felt essential to

have complete flexibility of action, and a decision was made to provide a 7-option fuze, to include:

Radar air burst 1 with safe-separation time 1
Radar air burst 2 with safe-separation time 2
Radar air burst 1 with safe-separation time 2
Radar air burst 2 with safe-separation time 1
Timer air burst 1 with safe-separation time 3
Timer air burst 2 with safe-separation time 4
Contact burst with safe-separation time 5.[19]

Subsequently, Sandia made a survey of weapons then being designed, and proposed use of a tactical fuze on the Mk 7 and Mk 12 Bombs. This proposal would have standardized fuze design and simplified pilot operation, but a decision was made that flexibility was preferred.

The initial provisions for bomb carriage included a Navy wing rack with a separation of 14 inches between attachment lugs and an Air Force rack with 30 inches between lugs. In late 1951 the Navy changed the 14-inch rack to a 20-inch design. It was subsequently suggested that the mid portion of the bomb case be strengthened so that sway bracing would not damage the case. Initially, it was requested that work continue on the original case design, and that the strong case be provided in a modification, and this proposal was accepted by the Military Liaison Committee July 9, 1952.[20]

The barometric switches were deleted in early 1952.[21] A decision had been made to use the TX-12 only as a tactical bomb and in low-altitude releases.[22] The baroswitches were then unnecessary, as they were designed to prohibit arming of the X-unit at high altitudes and prevent inadvertent arcing. Additionally, low-pressure testing of X-units had demonstrated that there was little possibility of such arcing at altitudes up to 50,000 feet.

modification program, called the TX-12-X2, was instituted to provide a more rugged fin, a more powerful operating motor, and a gear train to carry heavier loads.[34] This modification was scheduled to appear in stockpile during December 1956, but difficulties with the fin actuation mechanism delayed production of acceptable Mod kits of the Mk 12 Mod 1 until February 1957. The stockpile was completely modified by November 1957, with the allowable fin operating speed being increased to 220 knots. Simultaneously, a set of canted lugs was provided, to provide better compatibility with AD-series aircraft.[35]

Mk 12 Warhead

The Military Liaison Committee notified the Division of Military Application February 1, 1951, that the Air Force was contracting for Navy Bureau of Ordnance development of an air-launched, free-flight rocket.

(b)(3)

This information was forwarded to Santa Fe operations Office with a request that some thought be given to this usage, but that work on the TX-12 Bomb not be delayed.[37]

Additional criteria covering this rocket-warhead combination were furnished by the Division of Military Application March 13, 1951. Possible uses of the weapon included support of troops and defense against mass aircraft raids. Since it was desirable to carry the weapon on small, fast aircraft, its size and weight were to be as small as possible, and it was hoped that the weapon shape would have minimum effect on aircraft performance. The range of the rocket would enable safe escape of aircraft and crew after weapon launch.

(b)(1), (b)(3)

It was noted that a time fuze might be best for certain targets, but that requirements for accuracy of burst height in low-altitude deliveries might well require a target-triggered system.[38]

(b)(3)

Subsequently, November 16, 1951, the Committee on Atomic Energy of the Research and Development Board (the postwar replacement of the Office of Scientific Research and Development) noted that the ability to transport and direct atomic warheads against military targets constituted a most serious problem. The Committee noted that, with development of smaller and lighter atomic warheads, delivery would no longer be restricted to large bombers, and that guided missiles and rockets would be available in the near future. The report urged that high priority be given to the development of an air-to-ground rocket with an air-burst atomic warhead, to be used by attack and fighter aircraft making target approaches at low altitudes.[41]

The Military Liaison Committee notified the Division of Military Application February 10, 1953, that the Joint Chiefs of Staff had established a formal requirement for development of surface-to-air missiles with atomic warheads. The immediate objective was the design of an air-defense system to deliver an XW-12 Warhead by means of the TALOS-W missile.[47] The TALOS was 30 inches in diameter and 30 feet long, and was in the shape of a cylinder with one set of four stubby fins at its midpoint and another set at its tail. The missile was fired vertically, then programmed over into horizontal flight at a speed of Mach 2 to its target, which could be 60 miles distant. The Atomic Energy Commission would provide the warhead, and the Bureau of Ordnance would have responsibility for the rest of the weapon, with the Johns Hopkins Applied Physics Laboratory acting as prime contractor for the Navy.

It was planned to carry engineering studies through detail design and fabrication of a limited number of nose sections, complete with simulated warheads or warhead components. These nose sections would be combined with tail sections and subjected to flight tests, starting December 1953, as the final step in establishing the feasibility of the missile as an atomic warhead carrier. A TALOS-W Coordination Committee was appointed and held its first meeting March 4, 1953,[48] and the program was placed in design development stage March 6, 1953.

The Coordination Committee met April 10, 1953. Sandia discussed safing and arming problems, and proposed that 5000 feet be established as an adequate safe-separation distance and that, for failures just off the launcher, there be no self-destruct provisions. Likewise, in the late boost phase and in the time interval between separation and the end-of-being captured phase, there should be no self-destruct provisions, as nuclear arming would not have been initiated by this time. For subsequent failures it was recommended that self-destruction be required. The Atomic

Energy Commission would supply the warhead, with all necessary testing and handling equipment, and the Navy would be responsible for the adaption kit, including the warhead primary power supply.[49]

Field Command proposed, May 15, 1953, a set of military characteristics for an air-defense warhead having an outer diameter of 22 inches.

(b)(1), (b)(3)

Due to a possible requirement for high quantities, it was requested that the warhead have minimum nuclear and monetary cost.

A maximum weight of 650 pounds and a length of 60 inches was desired. The warhead would have to withstand accelerations of ±50 g's along the longitudinal axis of the warhead and 10 g's along any axis perpendicular to this. Other environmental conditions included temperatures from -65°F to +165°F and altitudes from sea level to 80,000 feet. Nuclear insertion should be possible at any time during warhead flight except during high acceleration and boost. Operating cycles should not exceed 6 seconds for insertion, nor 3 seconds for retraction. The warhead, except for the nuclear capsule, should remain functionally ready for periods of at least 6 months when installed in the missile. The nuclear capsule should be capable of storage in the insertion mechanism for at least 30 days.[50]

The Bureau of Ordnance notified Field Command June 23, 1953 that the XW-12/TALOS-W warhead installation could meet some, but not all, of the above requirements for an air-defense warhead. It was pointed out that the proposal to the Joint Chiefs of Staff had been based on use of TX-12 Bomb components in the XW-12 Warhead. This did not provide an optimum weapon, but the decision appeared both practical and in the best interests of the Services. The Bureau noted that early flights of the TALOS-W program were scheduled for December 1953, that airframe hardware had been released for production, and that the first missile was being assembled. It was felt that the nuclear capsule could not resist a 30-day storage period in an uncontrolled atmosphere.[51]

At the meeting of the TALOS-W Coordination Committee on June 25, 1953, Sandia stated that delivery of production-type warheads to stockpile could be made by June 1955, provided that the approved military characteristics were similar to those proposed by Field Command and that an early resolution of the self-destruction problem could be achieved. Development of a new and smaller X-unit, which had been under way at Sandia since January, was given Committee support. Production of the TALOS-W by the Navy was promised for early 1955.[52]

The August 4, 1953 meeting of the Coordination Committee heard a Sandia report on the self-destruction mechanism. This report proposed rapid retraction of the nuclear capsule, achieved by applying a higher voltage than normal to the mechanism. This, combined with a modification to the retraction gear ratio, promised a faster retraction time than previously believed possible. The Committee approved the proposal and requested that Sandia provide a detailed design.[53]

The Armed Forces Special Weapons Project in Washington notified Field command, October 6, 1953, that the XW-12 Warhead should use as many components from the TX-12 Bomb as possible, in order to accelerate development of the warhead. It was recognized that the XW-12/TALOS was not an optimum warhead for air-defense use, as it made uneconomical use of fissionable material, could not operate at high altitudes without an artificial environment, and could not withstand long storage in the operationally ready condition (that is, with the nuclear components installed in the nuclear insertion mechanism), without an artificial environment. However, no changes which would delay development would be allowed unless these were required to ensure proper operation. It was hoped that the weapon would provide an interim capability with at least some of the desired characteristics. Complete design release of the warhead installation was scheduled for the second quarter of 1954, first production by the second quarter of 1955, and stockpile entry in the third quarter of 1955.[54]

Meanwhile, the Bureau of Ordnance had noted that the design of the missile/warhead had progressed to the point where it was necessary to provide a definite division of responsibilities in the development of the warhead adaption kit. The TALOS-W warhead was contained in an isolated inner body which held only the warhead and some adaption-kit components, all of which performed functions relating to warhead operations. It was thus felt that the Atomic Energy Commission should assume development responsibility for these components in order to assure proper warhead functioning, and the AEC was requested to take over cognizance of the safing and arming system, the self-destruction system, plus hardware and adapters.[55]

The Santa Fe Operations Office replied that prime responsibility for design and development of the TALOS-W adaption kit rested with the Bureau of Ordnance, and that there was no compelling reason to reassign any of the portions of the adaption kit. However, the AEC, in a subcontractorlike role, could undertake to design and develop any portions of the kit for the Bureau of Ordnance on a reimbursable basis.[56] This information was forwarded to the Navy Department by the Division of Military Application.[57]

Field Command wrote to AEC-Sandia January 18, 1954, noting that the use of an artificial environment, to ensure warhead operability at all TALOS-W flight altitudes, would be acceptable in order to expedite design release of the warhead installation. However, it was requested that Sandia continue work on a warhead capable of operation at altitudes up to 60,000 feet without an artificial environment in the TALOS-W, and up to 100,000 feet in other applications. Hopefully, components so developed could be used in any air-defense warhead.

Sandia replied, February 2, 1954, that the warhead was located in the duct of the missile's ram-jet engine, where the pressure was greater than in other locations. This, of course, did not exactly provide an artificial

malfunction on another. All warhead components had been design-released, and drawings and specifications had been completed and filed for possible future reference.[64]

On November 21, 1955, the Assistant Secretary of Defense officially terminated the XW-12/TALOS-W project.

Glossary of Mk 12 Terms

Abee -- A radar design that superseded the Archie, a development of the "Tail-Warning Charlie" radar that signaled the approach of an enemy aircraft.

Adaption Kit -- Those items peculiar to the warhead installation less the warhead; namely, the arming and fuzing systems, power supply, and all hardware, adapters, and the like, required by a particular installation.

AEC-Sandia -- The Sandia Field Office of the Atomic Energy Commission.

Albert -- A radar design that superseded the Abee.

Armed Forces Special Weapons Project -- An interdepartmental agency formed to handle military functions related to atomic weapons.

Assistant Secretary of Defense -- Created by Department of Defense directive June 30, 1953, as part of DOD reorganization. Handles research and development activities of the DOD.

Barometric Switch -- A switch actuated by air pressure.

Bureau of Ordnance -- That part of the Navy Department having to do with design and procurement of ordnance.

Capsule -- The nuclear ~~assembly~~ element of an atomic weapon which, when subjected to compression in the implosion process, becomes supercritical and produces a nuclear reaction.

Centrifuge -- A device employing centrifugal force to stress weapons components. Consists of a horizontally mounted arm. On one end of the arm is placed the item to be tested; on the other end of the arm is placed a rocket engine. Firing of the rocket causes a high rotational speed of the arm.

Contact Fuze -- A fuze that detonates the weapon by contact with the ground or the target.

Detonators -- ~~Devices containing bridge wires which, when subjected to an electrical current, burn rapidly and act as a match to apply a flame to various points on the outer surface of the high-explosive sphere.~~ Explosive devices which when initiated by the X-unit signal the lens charges of the high explosive sphere.

Division of Military Application -- An AEC office that functions as liaison between the Military and the weapons designers and producers.

Field Command -- The local office of the Armed Forces Special Weapons Project, located on Sandia Base, New Mexico.

Fuze -- A combination of the arming and firing devices of a weapon.

Guided Missile -- A trajectile that is directed to its target while in flight or motion, either by a preset self-reacting device within the trajectile or by radio command outside the missile.

Implosion -- The effect created when a sphere of high explosive is detonated on its exterior surface. The force of the shock wave is directed largely toward the center of the sphere.

Inverter -- A device for converting direct current into alternating current.

Joint Chiefs of Staff -- An Army-Navy-Air Force group to determine policy and to develop joint strategic objectives of the Armed Forces.

Joint Task Group -- A military group established to test the stockpile-to-target sequence of a weapon.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Mach -- A measure of speed. Mach 1.0 is the speed of sound, or 738 miles per hour at sea level.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense committee established by the Atomic Energy Act to advise and consult with the Atomic Energy Commission on all matters relating to military applications of atomic energy.

Missile Warhead -- The explosive or nuclear device carried by a missile.

Operation Tumbler-Snapper -- See Tumbler-Snapper.

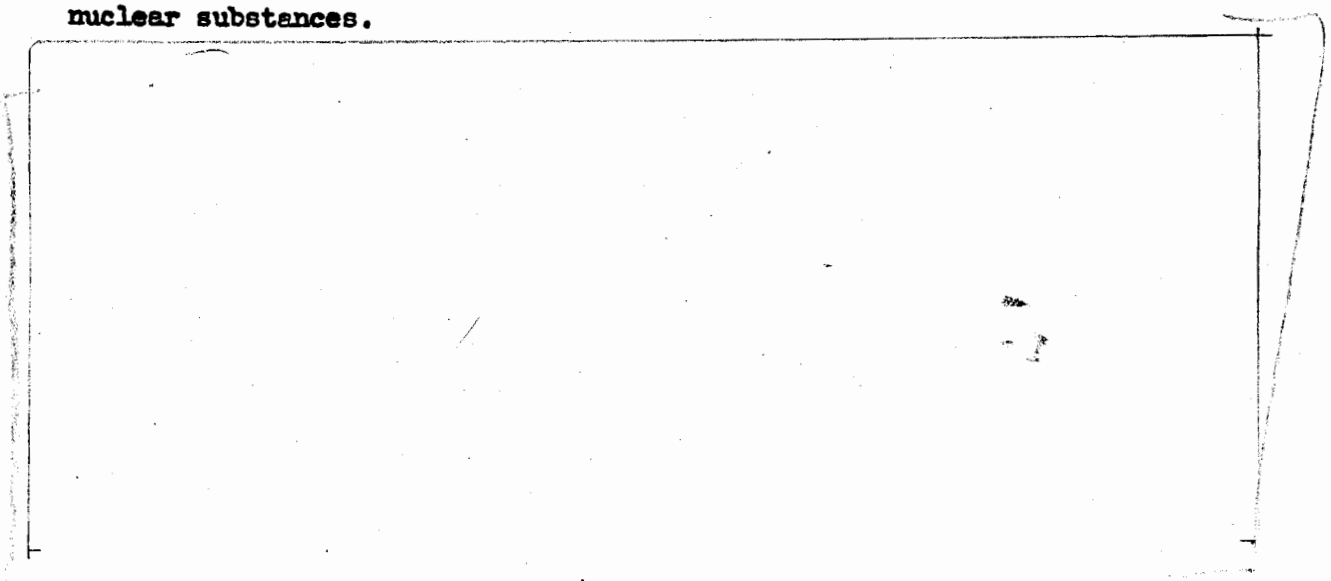
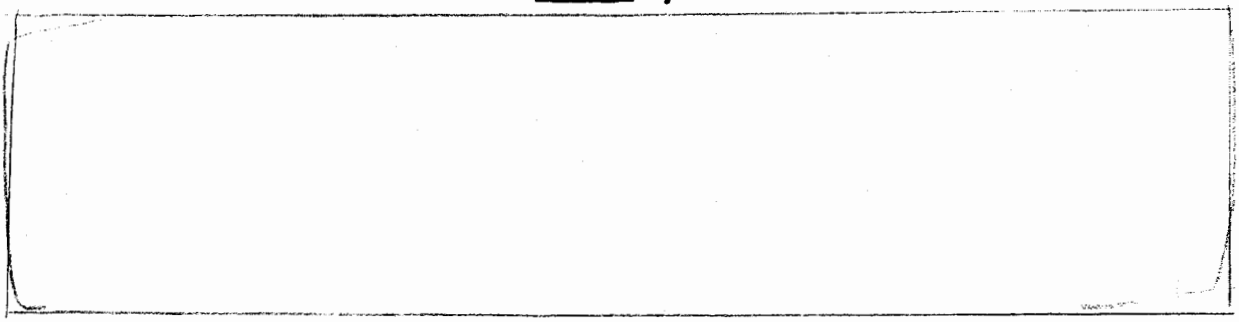
Introduction

In this discussion the following general scheme is considered. By an explosion of one or several conventional auxiliary fission bombs, one hopes to establish conditions for the explosion of a "principal" bomb. This latter may be either a fission or a thermonuclear assembly.

We propose to discuss certain general features of such an arrangement. The main purpose of the "auxiliary" system is to induce very high compressions in the principal assembly. It is known (L. W. Nordheim, unpublished data) that, for example, in the "Alarm Clock" high compressions of the active core will permit economy in the tritium put initially into the system and may be instrumental in starting thermonuclear reactions in assemblies of a feasible size. Ordinarily one uses high explosives as the auxiliary system. Great compression can be obtained, but the size of the highly compressed region is small. In certain thermonuclear arrangements, like the Alarm Clock, the size and the mass of the material to be compressed is so great that inordinate amounts of HE would have to be used. We have the following situation in mind, as an example.



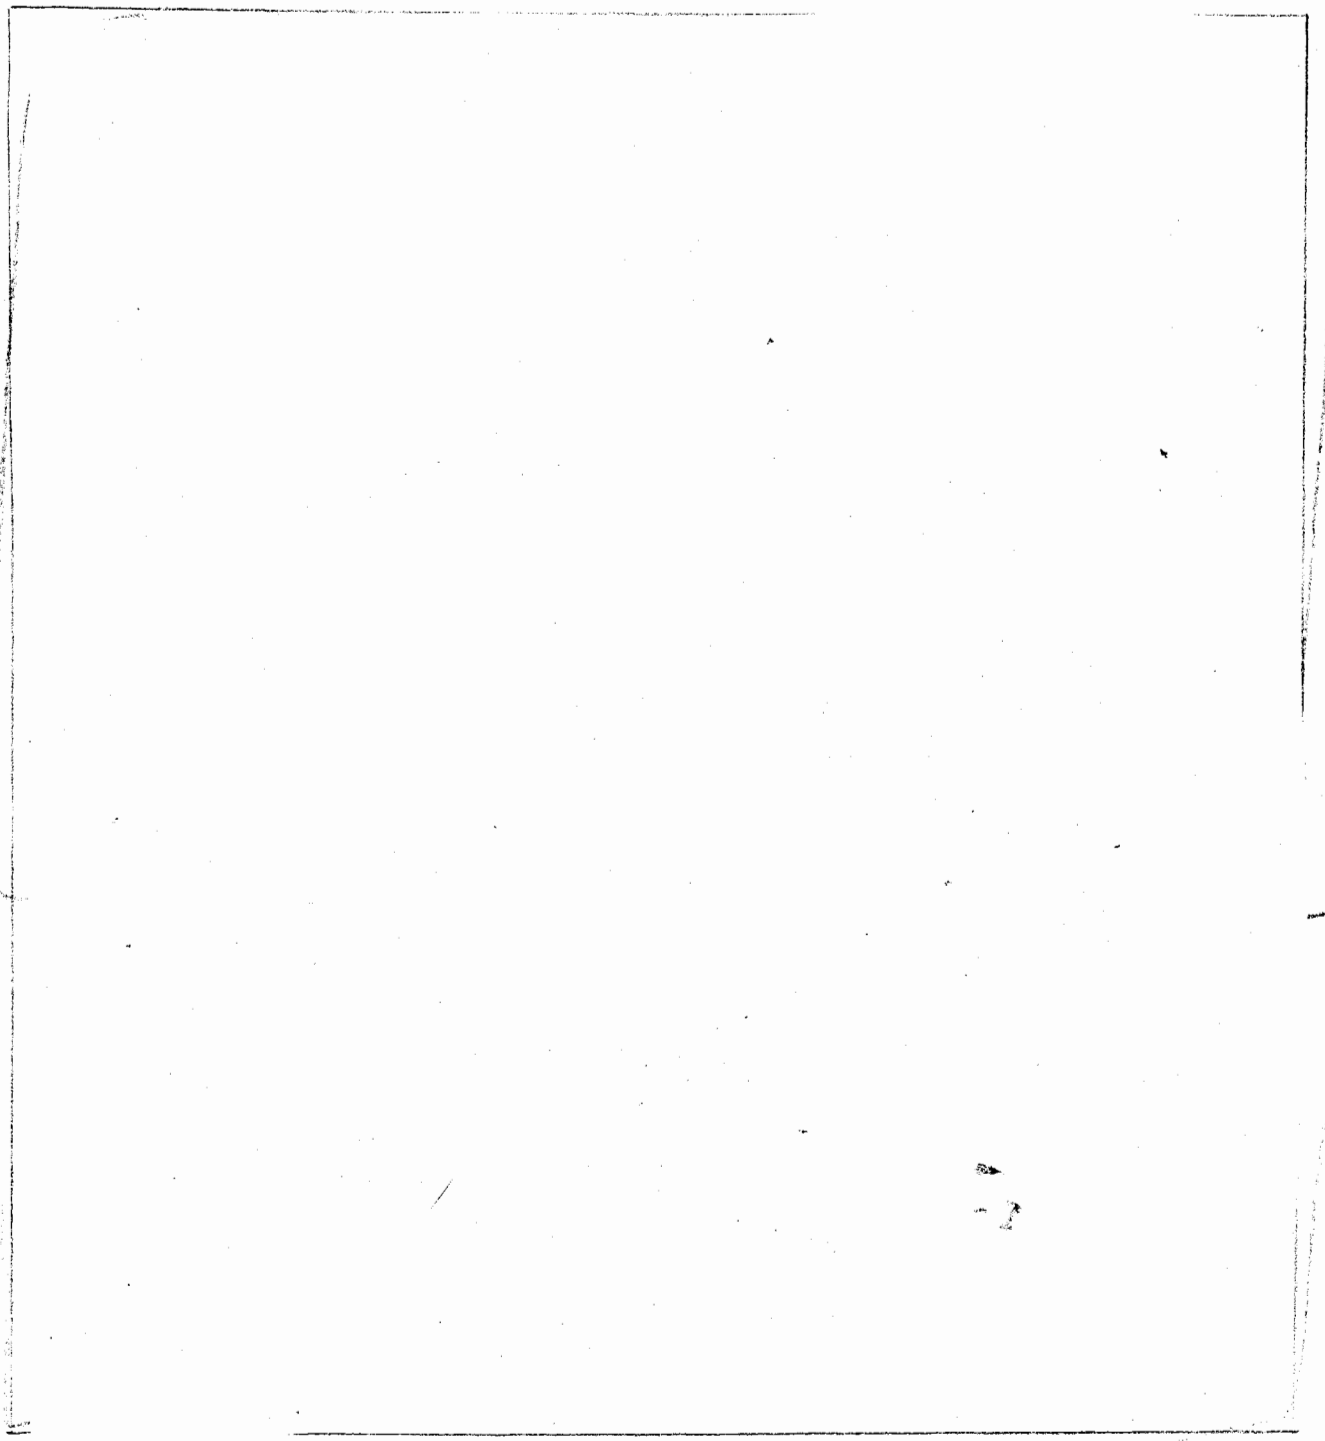


63

We shall discuss in the sequel the hoped-for compressions.

The arrangement might be called heterocatalytic, involving as it does a setting off of a reaction in one system by a reaction started in another material--the "auxiliary" arrangement is located at a considerable distance (from the purely nuclear point of view), like 50 cm to 5 meters. This is in distinction to hitherto-considered auto-catalytic schemes based essentially on self-implosions of a mixture of nuclear substances.

63



The difference of sound velocities is due to three reasons. One is the difference in average atomic weights, due primarily to the different degrees of ionization. Thus a light element like carbon would be almost completely ionized and would behave like a gas of approximate atomic weight 2. Uranium, on the other hand, would suffer approximately 10-fold ionization and would have an effective atomic weight near 8. The ratio four in atomic weights would give rise to a factor two in sound velocities. The higher velocity is of course to be expected in carbon.

A second reason for a difference in sound velocities is the fact that a completely ionized material acts like a monatomic gas with $\gamma = \frac{5}{3}$, whereas uranium, in which ionization is still proceeding, has probably a γ-value near 1.4. This will increase the ratio of sound velocities by another 10%.

The third reason is that the same shock strength will produce a lower temperature in a material of higher density since in each material the given energy density is distributed among more particles. This effect might give rise to temperature ratios as high as a factor four and to sound velocity ratios as high as a factor two. (In principle this effect could be made even greater but one would soon begin to lose by poor matching of acoustic impedance.)

It is, therefore, reasonable to assume that materials can be found in which sound velocities differ by a factor somewhere between 2 and 4. There should be no difficulty in making materials of any intermediate sound velocity.

[redacted]

In fact, the essential parts of the design do not depend sensitively on complicated shapes and the necessary planning is, therefore, comparatively simple.

The proposals are outlined here extremely sketchily. Quantitative work to elaborate these general suggestions would have to include the following calculations:

CHAPTER I

Summary of SFO Progress, 1947 to 1954

Santa Fe Operations fulfilled its mission assignments for the period July 1947 to January 1954. Atomic weapons of required efficiency, variety and utility were developed, produced and placed in stockpile in conformance with constantly expanding military requirements and approved schedules. New weapons of greater destructive power, of greater efficiency, and of at least equal variety and utility were in development prior to production or were clearly foreseen as a result of research. A major store of other knowledge of great value to other national programs, such as military utilization and civil defense, was obtained through SFO or SFO-related activity.

Weapons-wise, the six and one-half year period encompassed the A-bomb or fission stage and concluded well beyond the threshold of the H-bomb or thermonuclear stage. History may refer to the period by its weapons, A-bomb and H-bomb. In the memory of SFO management it may well be characterized as the building period. It extended from the beginning to the essential completion of the job of building the organization, the physical plant, and the basic programs required for mission accomplishment.

Weapons-wise and otherwise the final six months, July 1 through December 31, 1953, were a period of transition. As of July 1, management was already shifting from the phase of major stress on organizing and building to one of major stress on consolidating and tidying-up administration and operations. Midway in the period the direction of the implosion weapon program was reversed from added expansion to major retrenchment when the Military slashed its requirements for training and for stockpile. As the period closed, plans for one new high explosives plant and projected increases in facilities at two others had been cancelled and studies were under way to determine the degree of need for the remaining high explosives production facilities. Accompanying the cutback on implosion weapons was a military determination for concentration on thermonuclear weapons. As the period closed, plans were under way for achieving the scheduled production, but largely through organizations and facilities already established during thermonuclear development. As in weapons, the final six months also brought major developments in other phases of Santa Fe Operations. Planning was well under way at the close of the period to adjust to the changes involved in bringing San Francisco Operations Office and the Livermore Laboratory into SFO, and to those involved in concentrating on development and production of thermonuclear weapons. ALOO

Because of the tremendous gains made in the past six and one-half years, and the remarkable crystallization of a large development and production complex achieved since mid-1950, SFO had never before been so ready to meet expanded and urgent national requirements. Starting almost from scratch, without adequate tools to perform its mission, it had forged its tools and at the same time achieved its atomic weapons mission. Today its organizational structure and large plant complex is at once basically sound enough to stand the load of increased and new requirements, and flexible enough to adapt to changed circumstances.

6

[redacted]

1. JULY 1947 TO JULY 1950

The newly-created Atomic Energy Commission took over responsibility for the atomic energy program on January 1, 1947. On July 2 the Office of Santa Fe Directed Operations (now Santa Fe Operations Office) was established to administer the atomic weapons field program. Two weeks later, the present Manager of SFOO arrived at Los Alamos to be the first civilian manager of the project.

In mid-1947, Los Alamos Scientific Laboratory, assisted by a small Sandia Branch, was carrying the major weight of weapons manufacture. There was some production of mechanical components at the Army's Rock Island (Ill.) Arsenal. The Salt Wells Pilot Plant of Naval Ordnance Test Station, Inyokern, California, was producing high explosives. There was little participation by private industry. Two weapons types were being produced in extremely limited quantity. Units going into stockpile were laboratory-fabricated. The limited production chain had only one source for each major component. Three major modifications of one Mark weapon were in early development.

The SFOO assignment at the beginning of its operations represented a tremendous undertaking. It was required to build the mandatory physical plant and organization, while at the same time assuring continuous production of weapons, and maintaining basic and applied research for development of more powerful, more varied, or more efficient weapons. The scope and priority of initial assignment were direct reflections of the situation:

> To build and develop at Los Alamos, the heart of the program, a community that would be adequate to obtain and to retain the type of personnel required. This meant rebuilding and expanding the community.
>
> To provide a climate in which LASL could proceed with its job of basic nuclear research and development, and to provide a Technical Area physical plant adequate for the job.
>
> To organize and supervise an ordnance development, production, and testing complex, relieving LASL of these responsibilities.
>
> To expand production and facilities at other sites, in order to achieve a continuous flow of component parts.
>
> To evolve an organization competent to achieve basic management and program objectives.

ALOO

Approximately two and one-half peacetime years provided a relatively secure period unhampered by wartime expediencies, during which programs could be adequately planned and activated. The value of time for orderly development of a basic SFO structure was underwritten by national and international events near the end of the period. In the Autumn of 1949 Russia tested an atomic weapon, and SFO moved immediately out of its "peace-time" period into one of increased mission urgency and of "crash" programs. This was intensified in early 1950 with the decision to go all out on thermonuclear weapon development. It was further intensified three days before the end of the reporting period by the outbreak of the Korean War.

DOE/AL

[redacted]

Subcommittee, consisting largely of SFO contractor personnel, made two major recommendations in the interest of reduced security costs without weakening national security: (1) Recognition that no security is involved in approximate yield of nuclear detonations in Nevada; and, (2) application of the reactor field's "black box" idea to those items of nuclear weapons which are clearly of a military and not AEC nature. A field classification board was established at Sandia in addition to the one at LASL.

Declassification

Declassification is necessarily highly centralized and is performed for SFO by an Assistant Director, LASL, advised by Senior and Responsible Reviewers (the latter at LASL and Sandia) and by field classification boards. The normal tendency to overclassify has been materially reduced and a continuing program to review classified material for downgrading or declassification has been continued. Formal declassification was accomplished during the three years on 585 items from LASL and 16 from Sandia. Publication of "The Effects of Atomic Weapons" and release of information in the Rosenberg-Greenglass cases opened a fairly large field of information which could be considered for declassification.

Security

Considerable program stabilization was achieved while planning and activating "crash" basis expansion. To provide coordinated service over a wide geographic area, security offices were established in New York and in Los Angeles. As of July 1953, SFOO had security responsibility in 423 security facilities, 25 per cent of the entire AEC's facilities. A key achievement was segregation of staff and operating functions, with the Office of Security providing over-all direction and with SFOO Field Offices tending more toward local administration and less toward operations. For instance, installation guarding was being performed by contractor employees (or the Military) at all points except Los Alamos. Particular SFOO emphasis was placed on continuous review, evaluation, and coordination of security programs and measures throughout SFO. Careful analysis and action made possible a reduction of more than 50 per cent in ratio of guards to total Q-cleared work force at major SFO installations, the 1950 figure having been one to seven and the mid-1953 figure one to seventeen. Reductions in size of limited access areas and institution of various personnel security safeguards permitted a 3,750 reduction in number of Q-clearances processed in fiscal 1953 as compared with 1952. Two permanent panels of Personnel Security Board members were set up in 1950 to assist in administrative review of personnel clearance cases. Document control measures were intensified. Classified documents on hand June 30, 1953, totaled 53,000,000 with unaccounted-for documents totaling 840.

Information

There was a heavy, continuing output of classified reports, primarily by LASL and Sandia, with efforts being made to prepare them in a form not containing critical weapon data and so permitting wider classified distribution. LASL formed a Weapons Test Report section to replace special groups previously organized for each test series and to provide centralized and uniform handling, with 275 such reports issued prior to mid-1953. In addition to the requirement for technical reports, Sandia also had a heavy requirement for preparation of training manuals for the Military.

AL00

LASL and Sandia issued 493 formal, nonclassified reports on scientific and technological subjects during the period. There was a continuing flow of unclassified research material, particularly from UCLA's medical school.

[redacted]

CHAPTER II

The Weapons Manufacturing Organization

In accomplishing its primary missions of adding to the store of knowledge on the use of atomic energy for weapons and of delivering finished atomic weapons to stockpile, SFO operates in five broad areas: Government administration, research and development, testing, production, and storage. Two broad categories of components make up the final products: The explosive system (fissile and conventional) and the inert system (fuzing and case). Prior to July 1953, two general types of weapons were manufactured for stockpile: Implosion and gun, with the thermonuclear type still in the pre-stockpile-production stage. The technical and operating functions are performed almost wholly by contractors. The extensive organization of key, operating contractors is in turn supported by thousands of contracts with governmental, not-for-profit, and private enterprise agencies which furnish scientific, technical, production, and supply services. Government support and supervision are provided by a direct AEC organization in headquarters and field offices.

The initial three years of AEC stewardship were described as a period of building a staff, organization, and physical structure to match the developing programs. In July 1947, Los Alamos was the weapons organization. During the next three years the structure at Los Alamos was revised and strengthened, while simultaneously specialized capabilities were established elsewhere. In July 1950, it was projected that the basic structure was essentially complete, that only minor future expansion would be required. Reflecting new scientific discoveries and the changes in program requirements which developed after that date, the three years from 1950 to 1953 were in fact marked by major changes and expansions in the Santa Fe Operations organization—headquarters, field, and contractor—and in the physical plant.

This section presents an oversimplified picture of the development of philosophy, total organization, and plan of operations during six years from mid-1947 to mid-1953. It presents the key details of office and contractor location, physical plant, missions, and personnel. In order to show the full scope, a summary of the related Armed Forces organization is also presented.

4. FACTORS ENTERING INTO FIELD MANAGEMENT AND ORGANIZATION

ALOO

The mission assignment of SFO has remained unchanged, including research, development, testing, production, and custody of nuclear weapons. The scope has been materially expanded, for instance requiring organizational variations to cover implosion-type, gun-type, and thermonuclear weapons. A development in June 1952, was activation of Livermore Branch, University of California Radiation Laboratory, as a weapons development installation reporting to a new Operations Office at San Francisco. The new laboratory uses SFO facilities, particularly those at LASL, Sandia, Inyokern, and the two proving grounds, and

[redacted]

[redacted]

requires detailed coordination with Los Alamos and with Santa Fe Operations Office, but it reports to AEC staff divisions in Washington.

Full field responsibility for performance of mission assignments continues to rest with the Manager, SFO. The parallel full field authority delegated in 1947, in keeping with the original philosophy of full decentralization, has been progressively limited, in keeping with an apparent swing toward a philosophy of centralization which seemingly accelerated after late 1950. These limitations have not been expressed in a redefinition of Operations Office authority, but in a series of actions each of which removed the control of some aspect of day-to-day performance and placed it with a Washington headquarters staff office.

There have been two major changes since 1947 affecting the line of command through which the Commission directs the field program. In 1947, the Manager, SFO, reported to the General Manager, the chief executive officer, with the Division of Military Application in the position of a staff division; in September, 1948, the General Manager delegated direct supervision of SFO to the Director, DMA. Paralleling the swing to centralization which became apparent in 1950 there has been an intensification of direct control exercised by specialized Washington staff offices over counterpart phases of field operation, expressed not through the command channel but directly through functional channels.

The expressed philosophy of AEC operation has remained constant, being that the maximum degree of operations and supply will be performed through contract with private enterprise. The application of the philosophy in SFO has been reviewed on several occasions, specifically with regard to the Zia and the University of California contracts at Los Alamos and on occasion with regard to operation of production facilities by the Military. In keeping with this philosophy, SFOO's plan of management has been to retain final field responsibility and control, providing policy and regulatory framework, and requiring performance. Manufacturing responsibilities are assigned by SFOO to its contractors in order to utilize to the fullest extent possible the management know-how, operating skills, and efficiency of private enterprise. To the fullest extent possible, authority is also delegated by SFOO to its field offices and to its contractors. Staff functions are retained by the Operations Office headquarters and field office organization. Technical and manufacturing functions are delegated.

5. SANTA FE OPERATIONS OFFICE

Prior to 1947, the Manhattan Engineer District managed and operated the nuclear weapons field organization which was largely centered in Los Alamos. From January 1, 1947, when the newly-created Atomic Energy Commission took over responsibility for the atomic energy program, until July 1947 the Military continued to provide supervision at Los Alamos. On July 2, the AEC established the Office of Santa Fe Directed Operations (now known as Santa Fe Operations Office) to conduct the weapons program. Two weeks later Carroll L. Tyler arrived at Los Alamos, becoming the first direct AEC Manager.

One of his immediate jobs was to organize a staff. There have been numerous reorganizations since, but the general outline of the staff formed by late 1948 has remained constant, changes largely reflecting new areas of key interest. Near the end of the first three years, the Santa Fe Operations Office headquarters and field staff was revised as a start toward providing, on the one hand, an operations-wide administration and, on the other, a more clearly-defined administration of the Los Alamos community.

DOE/ALO

[redacted]

[redacted]

SFOO Transfer to Albuquerque

At the start of the present reporting period, July 1950, SFO headquarters was still at Los Alamos. It was then decided that reorganization and physical separation of SFO headquarters office from Los Alamos to another geographic location was desirable for several reasons: (a) Shortage of housing at Los Alamos; (b) rapid and widespread addition of SFO facilities outside of Los Alamos; (c) increased demand on the SFOO staff for supervision and coordination of programs extending beyond the Los Alamos area; and, (d) expansion in the testing, production, and stockpiling programs.

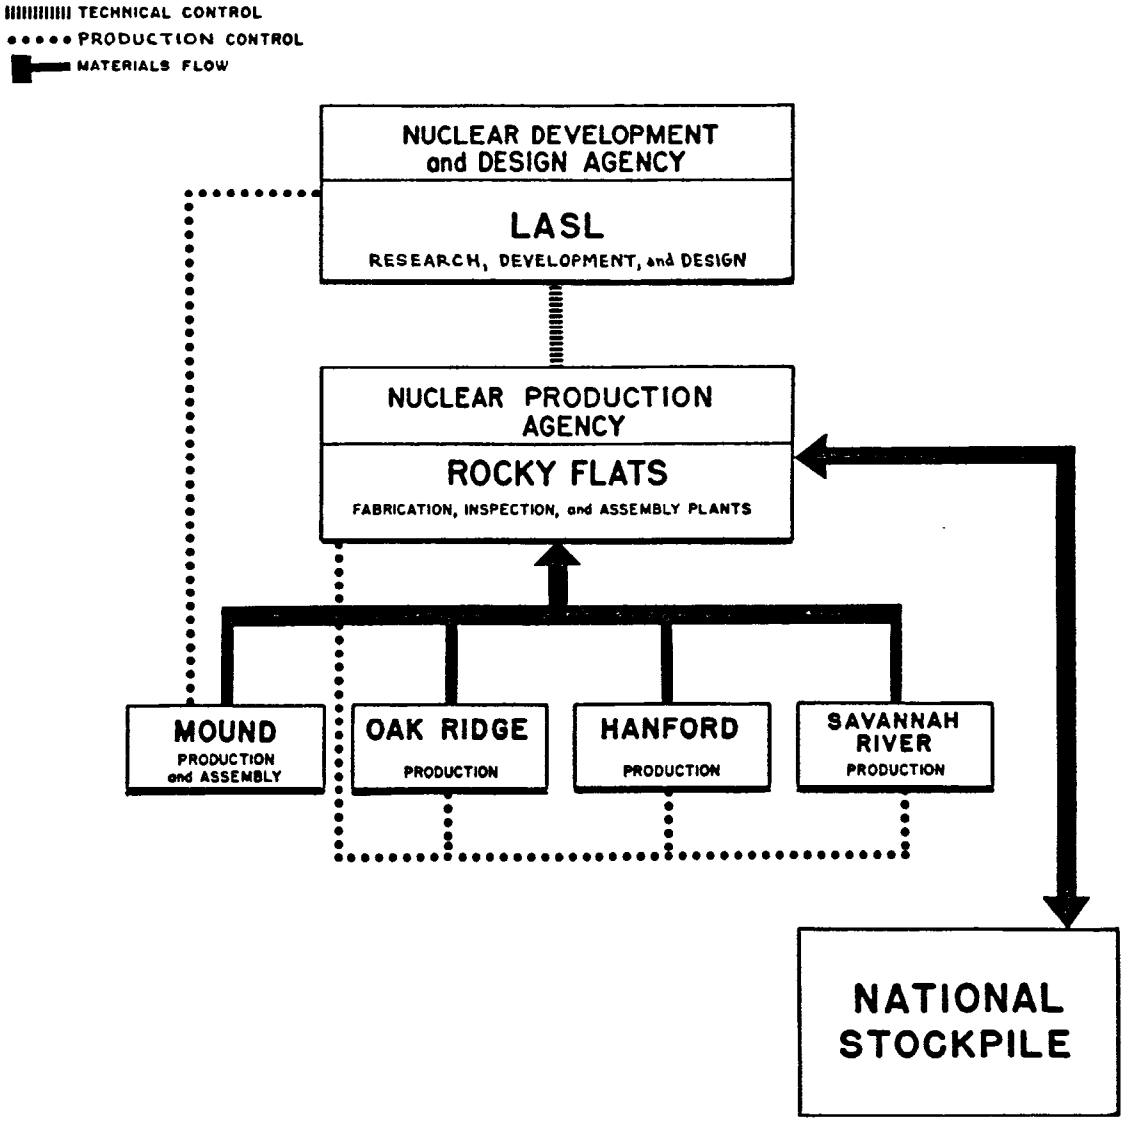
After considerable study Albuquerque was chosen as the location, and the former Simms Girl's School (then occupied by Sandia Laboratory personnel) was selected as the site. Albuquerque was selected after a survey of several cities because residential facilities were obtainable, major AEC and military installations were located there and contact with Los Alamos would not be difficult, and there was fair transportation to other SFO geographic areas.

SFOO was formally established at the Albuquerque location on June 18, 1951, and movement of approximately 300 employees was effected between August and October. Eleven staff offices and divisions at Los Alamos were transferred to Albuquerque. Also on June 18, 1951, the Los Alamos Field Office was created to take care of AEC interests at Los Alamos, and to it was transferred the Office of Community Management. LAFO became administrator for all phases, except program assumptions or changes thereto, of the Los Alamos Scientific Laboratory contract.

The reorganization and physical separation of SFO headquarters office from Los Alamos has resulted in improved SFO-wide planning, greater coordination and integration, more concentrated attention on local Los Alamos problems, and more effective staff utilization.

Development of Staff

The development of the present SFOO headquarters and field staff is indicated in the accompanying "Comparative SFOO Organization Chart 1950-1953." It is not fully descriptive. As of July 1953, SFOO had personnel assigned to numerous stockpile locations; had branch security offices in New York and in Los Angeles; had representatives stationed at Inyokern, Salton Sea, and Picatinny Arsenal; and had resident auditors stationed in Kansas City, Los Alamos, Los Angeles, and Rocky Flats.



The staff Office of Test Operations was established on December 26, 1951, reflecting the need which had developed during 1951 and which would continue. The Office of Patent Attorney was established on June 15, 1952, with transfer of the SFO-wide responsibility from the LASL Patent Attorney. Not shown on the accompanying chart are several technical staff functions, which have from the start been accomplished by technical contractor personnel as direct staff assistants to the Operations Manager. The Director, LASL, is in effect technical staff officer and additionally head of the SFO programs of classification and of declassification, functions which he delegates to his Assistant Director for Classification and Security.

ALOO

There have been continuing changes throughout the past three years in key staff personnel. In anticipation of the move to Albuquerque, George P. Kraker, then Sandia Field Manager, was transferred to a new position as Deputy Operations Manager. Present personnel are noted in accompanying illustrations.

[redacted]

NUCLEAR DEVELOPMENT and PRODUCTION OPERATIONS

AEC-SFOO
2/54

ALCO

DOE/AD

[redacted]

The Manager, SFO, presented a resulting "Management Plan for Implosion-type Weapons" to the Commission on September 22, 1952, explaining that the plan would set a pattern for bringing additional production agencies into the program as developments might require. The plan as presented featured two points:

> Divesting Sandia Laboratory progressively of production functions, so that it could concentrate on technical functions, applying to Sandia the same principle which had proved resultful for LASL.
>
> Concentrating production function responsibility in a single contractor agency, this principle having been approved as applied to the nuclear production field, conforming with the Panel's guidance, and having been recommended by Sandia and by Bendix.

The plan established that implementing action would begin immediately, with transfer of functions to be progressive, with an overlap of up to two years before a clear cut and complete division would be achieved.

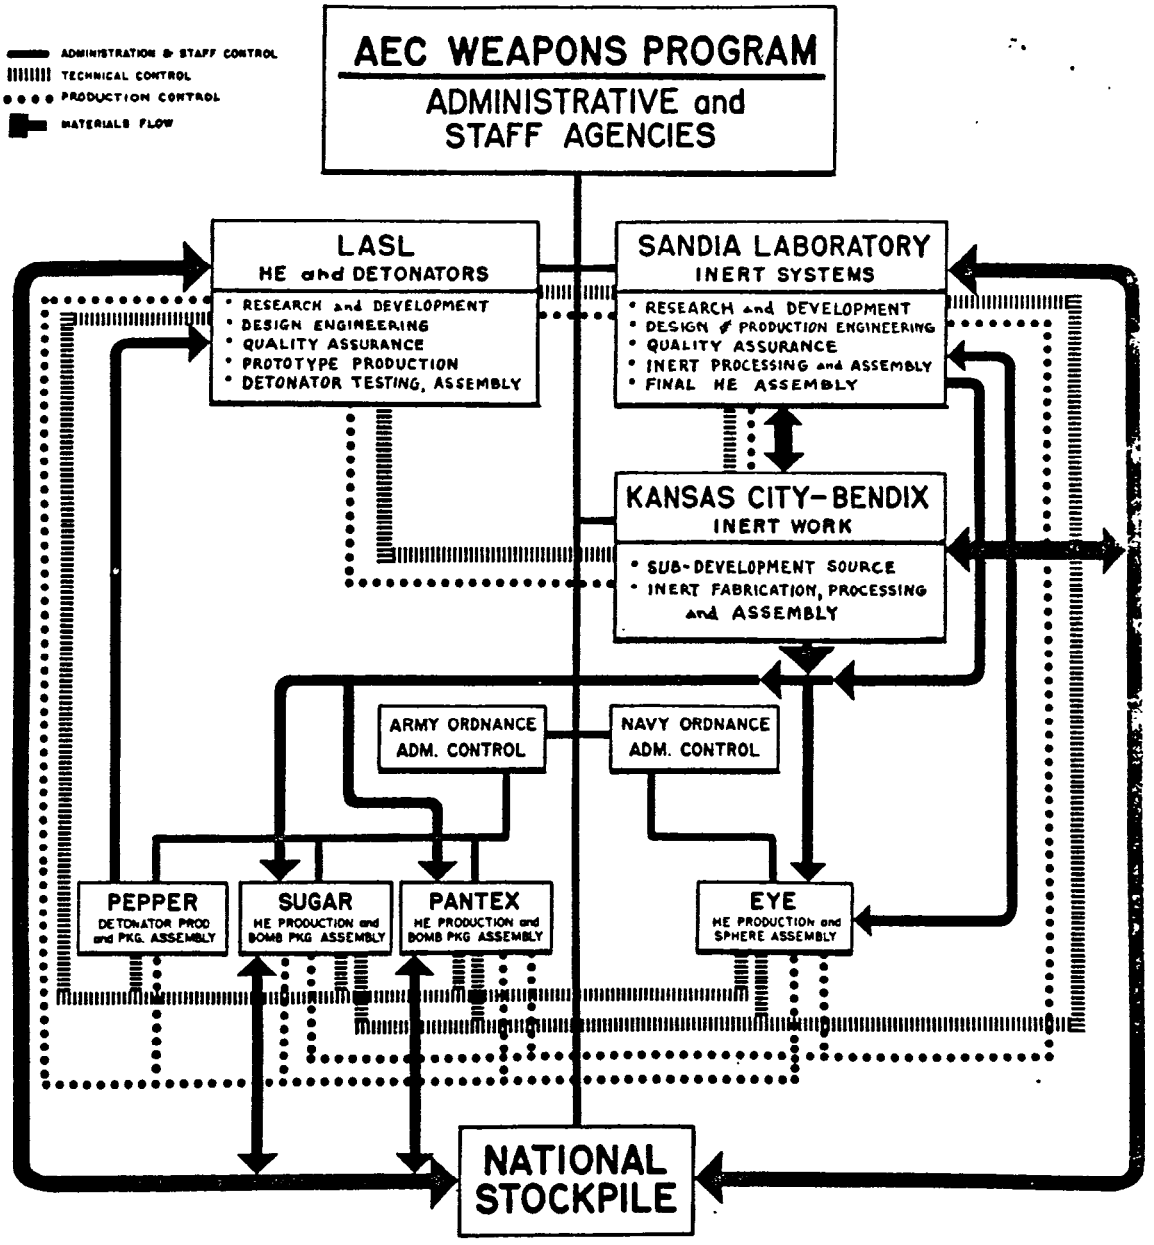
The full details of the plan presented in September 1952, have not been accomplished. There has been some divestment of non-developmental functions from Sandia Laboratory, and plans project accomplishment of this phase. Some production responsibilities have been transferred to the Kansas City plant. An Inter-plant Advisory Committee, of concerned plant, LASL, and SFOO personnel, has been established as a monitoring activity for high explosives fabrication and assembly.

The Mid-1953 Pattern of Operation Developed for Implosion Weapons

The operating philosophy thus proposed had been established for nuclear manufacture and for inert component development. It was uncertain whether it would be adopted for non-nuclear production. The pattern in effect in mid-1953 was as follows:

> Los Alamos, as the research, development, and design agency for the basic explosion system of all weapons;
>
> Sandia, as the research, development, and design agency for the inert system for all weapons to the extent that responsibility rests with SFO, and for related functions;
>
> Rocky Flats, as the production agency for nuclear components;
>
> Kansas City, becoming more and more a production agency for mechanical and electronic components; and,
>
> Inyokern, Burlington, Pantex, and Spoon River sharing production of high explosives.
>
> Picatinny Arsenal, producing detonators.

ALOO



The Nuclear Component System

The accompanying chart presents a clear picture of the system.

LASL, operated by University of California, was the nuclear development agency with full responsibility under AEC program approval and program controls. It had the technical

[redacted]

NON-NUCLEAR IMPLOSION WEAPONS OPERATIONS - JULY 1953

AEC-SF00
2/54

AL00

DOE/[redacted]

[redacted]

[redacted]

functions of: Research and development, product design, test and evaluation, quality assurance, and preparation of standards for stockpile surveillance. It performed only developmental and engineering production, including fabrication and assembly of nuclear components.

Rocky Flats plant, operated by Dow Chemical Company, when fully operative would be the nuclear production agency with full responsibility subject to AEC controls and to LASL technical supervision, probably for all weapons types. It would have responsibility for: Production (process) engineering; fabrication of uranium and plutonium units in its own plant, and procurement from AEC fabrication plants; receipt, inspection, and assembly of nuclear capsules, and shipment to stockpile; other phases of final inspection and assembly; other phases of nuclear production procurement; and assisting Los Alamos in process engineering during development by coordinating startup of new production at the other installations.

Included in the production system were:

Mound Laboratory, for initiator fabrication (reports to OROO);
Industrial sources, for container fabrication;

Oak Ridge (OROO), Hanford (HOO), and Savannah (SROO) for nuclear fabrication.

Procurement flowed from AEC plants and from private industry to the production agency; and final product flowed from the production agency to stockpile.

The High Explosive System

LASL remained the development agency for HE and detonator components, retaining technical functions only. It performed only developmental or prototype production, including fabrication and assembly. (As of July 1, 1953, shipment of detonators was still from producer to LASL but agreement had been reached to ship from producer to stockpile.)

Inyokern (California) Salt Wells Pilot Plant, operated by Navy Ordnance, performed process engineering, tooling design, and pilot plant for new HE, other HE fabrication and assembly.

Burlington (Iowa) plant, contract with Army Ordnance for operation by Silas-Mason Company, and Pantex (Texas) plant, contract with Army Ordnance for operation by Procter & Gamble Defense Corporation, performed HE production and weapon assembly.

Spoon River (Illinois) plant was under construction, to be operated by Thompson Products Company, initially for HE production and assembly. A second Project Plum was projected, in view of existing requirements, for HE production and weapon assembly, perhaps through addition of production lines at Burlington and Pantex.

Picatinny Arsenal (New Jersey), operated by Army Ordnance, performed detonator production.

ALOO

It was projected that over a period of years as Thompson Products developed a capability, responsibility would be transferred there for Inyokern's process engineering, tooling design, and pilot plant operation. Spoon River would thus become the leadoff plant on production of new models and development and procurement for the entire high explosive system.

DECLAS

[redacted]

The Inert Component System

Sandia Laboratory, operated by Sandia Corporation, remained the development agency for inert bomb and warhead installation components of all weapon types. It would eventually retain only technical functions, plus developmental or prototype fabrication and assembly.

Kansas City plant, operated by Bendix Aviation, was becoming the production agency for mechanical and electronic components. It might eventually have full responsibility, subject to AEC controls and to Sandia technical supervision. As of July 1, 1953, it had responsibility for: Some measure of process engineering; procurement from private industry; logistic support of HE plants; inert fabrication and assembly; and some base spares procurement.

The Pattern of Organization for Other Weapons Types

During the three years prior to July 1953, SFO developed and produced gun-type weapons and missile warhead installations, and conducted an extensive thermonuclear development program. The preceding paragraphs on development of the SFO organization for contractor operations dealt essentially with the organization for implosion-type weapons. There were variations and there were responsibilities assigned elsewhere as far as gun-type, missile warhead installation, and thermonuclear activities were concerned. These are described briefly below.

Gun-Type Weapons Manufacture

A penetration weapon program was operated jointly by SFO and the Navy. LASL was responsible for the nuclear phases. Sandia had responsibility for final design, environmental testing, development of handling equipment, and certain technical studies of fuzing and weapon effects. The Navy performed development and related production of the gun mechanism and ordnance.

Active work on development of an artillery-fired atomic projectile began after mid-1950. It was a joint LASL-Sandia program, with Picatinny Arsenal handling the bulk of the development work under SFO guidance.

As of July 1, 1953, responsibility for future gun-type work was divided: LASL and Rocky Flats, nuclear development and production; and Armed Forces (Army and Navy), non-nuclear design and production.

Missile Warhead Installations

Sandia Laboratory has been engaged actively in the development of atomic warhead installations for missiles, both guided and free ballistic, since October 1950. Inasmuch as the basic explosive system is in general identical with other implosion-type bombs, LASL has not needed to conduct developmental programs, Sandia now acting as the LASL agent in this respect. Future developments may bring LASL directly into the picture, as for anti-aircraft missiles.

AL00

Following considerable exploratory work, the Military Liaison Committee requested in November 1950 that atomic warheads be developed for a number of specified missiles. It became immediately apparent that in addition to problems associated with the basic warhead, integration of the missile guidance system and the warhead arming and fuzing system would constitute a major area of investigation and development; and that, aside from technical questions, division of development and production responsibilities between SFO and DOD

would require resolution. With concurrence of DOD and AEC, the Special Weapons Development Board was designated late in 1950 as the agency to determine division of arming and fuzing responsibilities. The Board did allocate and set up some Ad Hoc Working Groups. Subsequently, it was agreed that after the first four atomic warhead installations, the Military would assume the arming and fuzing responsibilities. As a consequence, the Ad Hoc Working Groups are now in the process of reconstitution into Joint Project Groups reporting to: the CG, FC, AFSWP; President, Sandia Corporation; and the designated DOD agency as principals.

Because of the large number of missiles designated to carry atomic warhead installations, it was evident that a high degree of standardization would be required. Considerable progress has been made in the direction of interchangeable warheads, not only between several missiles but also between a warhead and the associated free-fall bomb. This has resulted in the so-called "Maximum Bomb Availability Plan" whereby all warheads are to be stockpiled with their fuzes in bomb configurations until the bomb requirements are satisfied. Bomb-to-warhead conversion components and complements (analogous to fuzes) will also be stockpiled to provide the conversion capability to missile warhead installations when desired. Lately, considerable development effort has been devoted toward simplification of the bomb-to-warhead conversion process. Employment of standardized weapon components (i.e., baroswitches, radars, etc.), test equipment, and handling equipment has resulted in significant savings in both bomb and missile warhead installation programs.

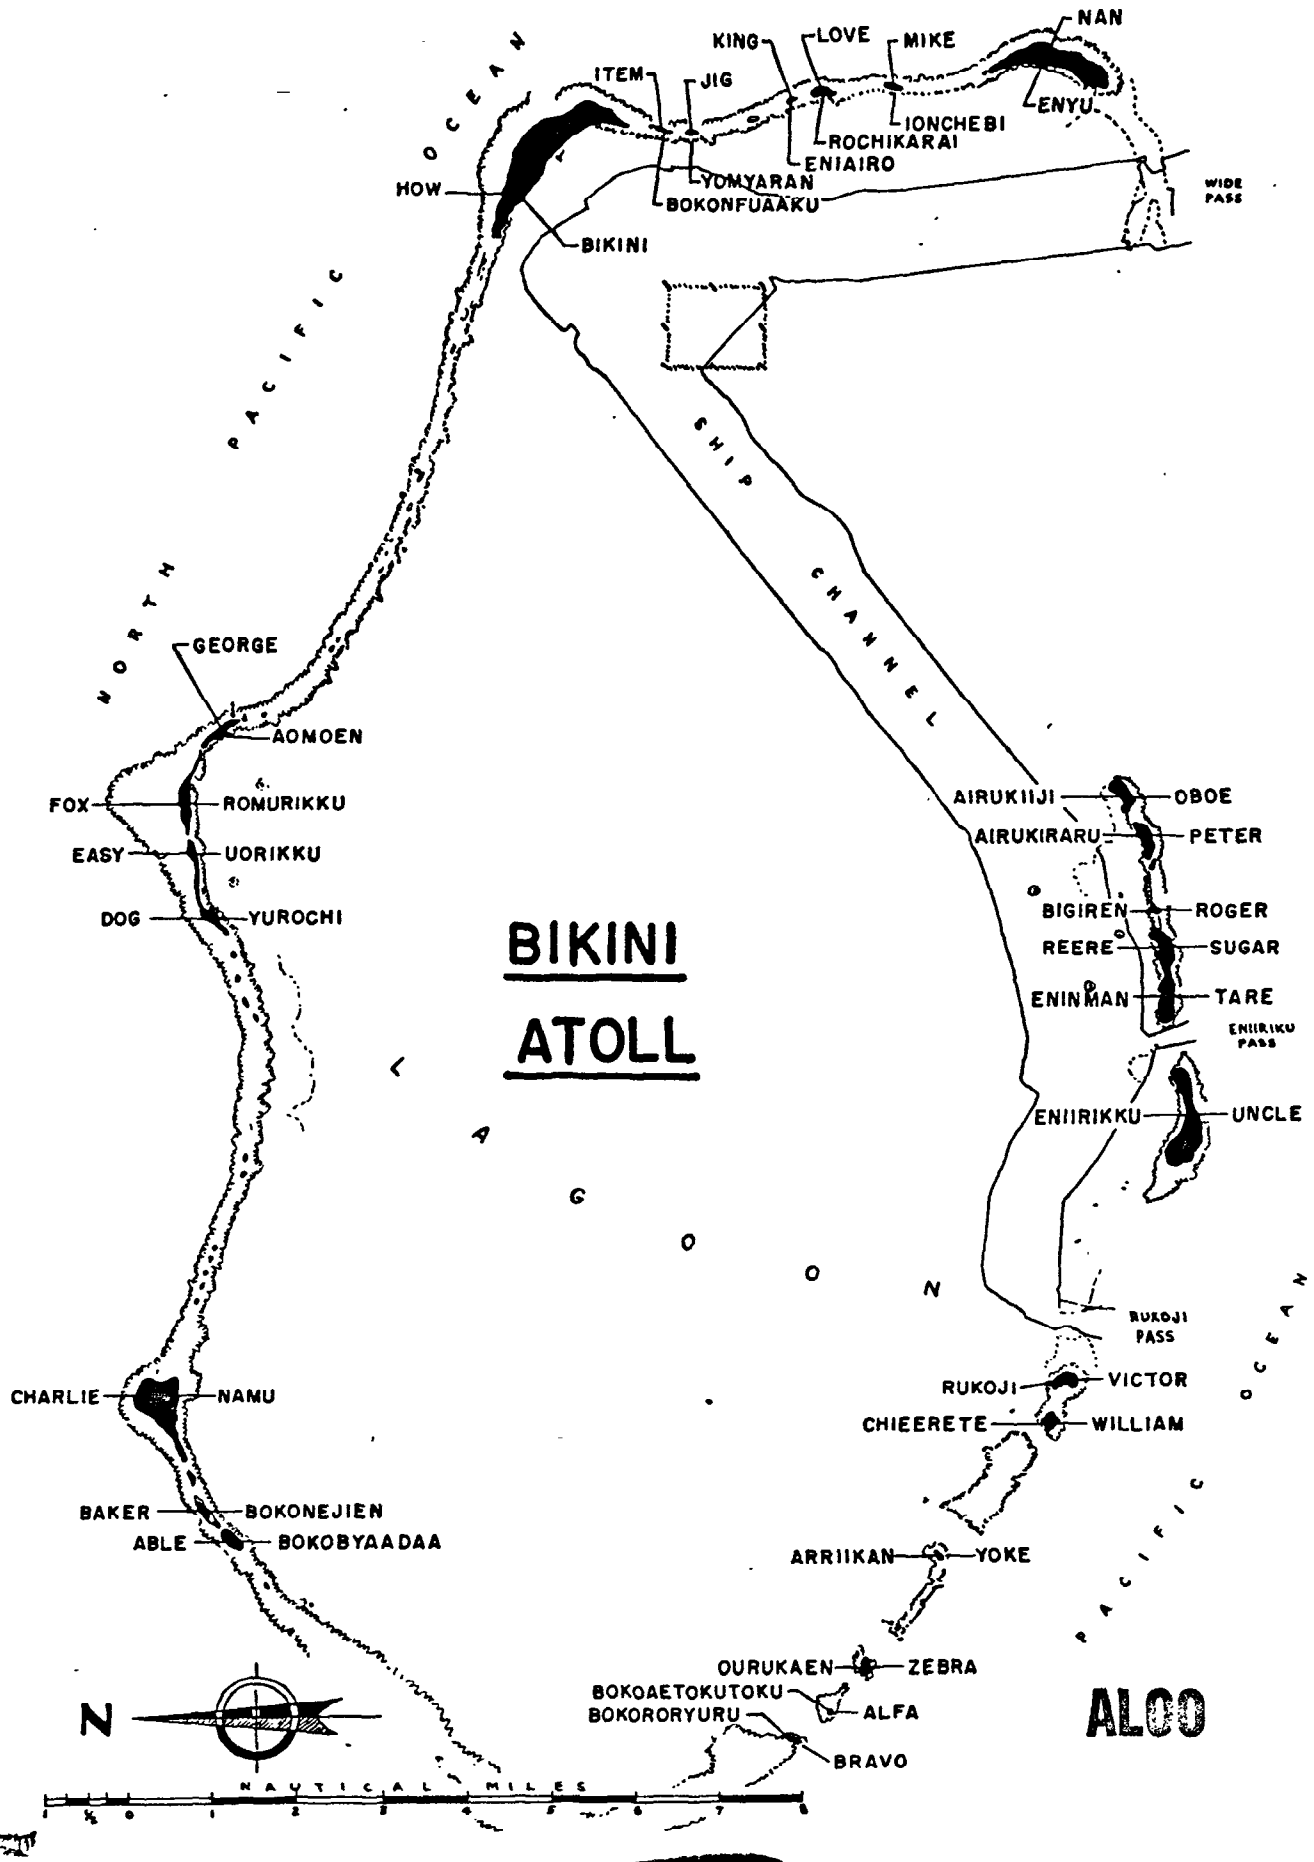
Thermonuclear Weapons Development

Since an intensified research and development program was directed in January 1950, primary responsibility has rested with Los Alamos Scientific Laboratory. During development an organizational framework was developed which included American Car & Foundry Company, and extensive cryogenics assistance from National Bureau of Standards, Cambridge Corporation, and Herrick Johnston. It may be assumed that the developmental organization will point the way for the production organization. Future production will require the resources of the nuclear, high explosive, and inert production system. Added to this will probably be the ACF, Cambridge, and NBS facilities to meet unique requirements.

The Organizations Developed for Nuclear Field Tests

Los Alamos Scientific Laboratory originally carried almost all of the SFO responsibility for nuclear field tests. LASL still carries very heavy responsibilities but by mid-1953 the technical responsibility was being shared by Sandia Laboratory and to some extent by Livermore, and a considerable measure of administrative responsibility had been transferred to SFOO, and, in certain respects, to military participants.

Overseas Tests



All overseas tests, beginning with Bikini in 1946, have been conducted by a joint task force commanded by a military officer and with responsibility for the scientific and technical phases and, beginning in 1948, many maintenance, construction and other support phases, resting with SFOO and its key contractors.

Executive agent responsibility has been rotated between the military departments with the Chief of Staff, U.S. Army, being agent for Sandstone; the Chief of Staff, U.S. Air Force, agent for Greenhouse; and the Chief of Staff, U.S. Army, agent for Ivy and Castle. During the period between operations, the JTF Commander's responsibility has been limited to planning and coordination of preparations for the operation, and to providing military support in the form of transportation, communication, etc.

9. THE MILITARY ATOMIC WEAPONS ORGANIZATION

The Armed Forces Special Weapons Project (AFSWP) has its headquarters in Washington and its Field Command at Sandia Base. It coordinates all military assistance to AEC and provides special services to the Army, Navy, and Air Force in the military application of atomic weapons.

It was activated on January 29, 1947, to provide a jointly staffed Army-Navy atomic energy organization. After passage of the National Security Act on July 29, 1947, the Air Force was represented.

Since 1947, the assignments of AFSWP have multiplied steadily. Its earliest functions included military participation in research and development of atomic weapons in coordination with AEC, and coordination through established agencies of the radiological safety measures of the Armed Services. Both of these functions applied to the 1948 overseas tests. In 1949, AFSWP was assigned responsibility for determinations in the field of effects of atomic weapons and participated heavily in the overseas and continental tests of 1950-1953.

On August 1, 1952, Field Command-AFSWP established a Directorate of Weapons Effects Tests. Its Director is a Deputy Manager for continental tests.

AFSWP now functions in the over-all military application of atomic energy for the Army, Navy, and Air Force by providing the following services: specialized training; storage and surveillance in conjunction with AEC; planning of continental and overseas tests with other affected agencies; determination of weapons effects; consolidation of Armed Forces' requirements for procurement of atomic weapons other than War Reserve requirements; assistance, as required, in the development of atomic weapons; assembling of atomic weapons; other technical services to the Armed Forces as required.

Air Force support of the Commission's atomic weapons program is a major factor in many phases of the program. Much of the responsibility, particularly in the testing phase, rests upon the Air Force Special Weapons Center, headquarters Kirtland Field, Albuquerque.

The Air Force Special Weapons Center evolved from the Tactical and Technical Liaison Committee established at Kirtland AFB in 1947 through the activation of the Special Weapons Command in December 1949, and the subsequent transfer of the Command to the Air Research and Development Command. It is now one of eight centers under the jurisdiction of the latter Command.

The mission of Air Force SWC includes development testing and operational suitability testing of atomic and other special weapons; research as related to such tests; the development of associated equipment for nuclear weapons; and planning, control, and operation of special test facilities. It provides support to the Commission and its scientific contractors, including LASL and Sandia Laboratory.

AL00

During the last three years, the Commission's relationships with the Military have become progressively more complex. The Department of Defense has entered the development field as a co-equal collaborator with AEC on numerous joint projects, with prime responsibility of its own in substantial areas of weapon development and design. As a result, it has become necessary to establish special direct working relationships with the individual services while being careful at the same time to insure that the values of AFSWP as an integrating agency are not lost.

DOE/ALO

[redacted]

[redacted]

AFSWP liaison officers continue on duty in many departments of Sandia Corporation, and maintain liaison with Los Alamos Scientific Laboratory. The Special Weapons Development Board, comprised of representatives of AFSWP, LASL, and Sandia Corporation, constitutes the official forum at which are developed formal recommendations on the development and standardization of atomic weapons. Guidance of joint AEC-DOD programs rests with Joint Project Groups whose membership comprises representatives of either LASL or Sandia, carrying the technical interests of AEC; the "cognizant service", Army, Navy, or Air Force, which carries the technical responsibilities for DOD; and AFSWP, which coordinates functions on behalf of all the Armed Services. Authority of the Joint Project Groups derives basically from general agreements between AEC and DOD.

CHAPTER III

Achievements and Nature of Mission Programs

By broad category, Santa Fe Operations conducts programs of research, development, testing, production, and storage, the results of which are measured by the store of knowledge valuable to military application and by the utility and numbers of weapons in stockpile. The purpose of this chapter is to summarize the mission achievements of SFO and to sketch the nature and something of the extent of operations in the Los Alamos and Sandia areas including nuclear field tests, and including with relation to stockpile production an indication of the extent of weapons inspection and scheduling activities.

10. SUMMARY OF DEVELOPMENT, PRODUCTION, AND STORAGE ACHIEVEMENT

In 1945, only two types of bomb—and only two bombs—were available to the Military. One of the most important fields of development for national defense was to provide wide ranges both in yield and in size and weight in order to allow the Military to select bombs appropriate to the target and to the available delivery vehicles. Another important reason for reduction in size and weight of bombs was to enable the Military to use a wide variety of vehicles to carry atomic bombs and to gain greater range of action through reduction in load.

Progress Made Since 1945 Through Research and Development

DELETED

(c) produced a range of implosion bombs now in stockpile varying in diameter from 30 to 60 inches, in weight from 1,600 to 8,000 pounds, and in yield up to [redacted] not including a smaller sized model in development; and (d) produced a system of interchangeable cores and bombs so that yield and bomb size can be chosen relatively independently.

ALOO

The advantages of flexibility indicated above are difficult to measure numerically, but are certainly comparable with advantages in increased efficiency of utilization of fissionable materials. The effects of the latter could have been accomplished by very large expenditures leading to increased production of fissionable materials, those of the former could not have been attained except through research and development.

[redacted]

STATUS AND NUMBER OF WEAPON PROGRAMS, JULY 1950 and JULY 1953
(Status and Number—see notes)

Program	Stage 1		Stage 2		Stage 3A		Stage 3B		All Stages	
	July'50	July'53	July'50	July'53	July'50	July'53	July'50	July'53	July'50	July'53
1. NEW WEAPONS										
(a) Implosion-Type Bombs	2	1	0	1	3	1	1	4	6	7
(b) Gun-Type Bombs	0	0	2	1	1	0	0	1	3	2
(c) TN-Type Bombs	0	2	0	3	0	0	0	0	0	5
(d) Artillery Shells	0	2	1	1	0	0	0	1	1	4
(e) Warhead Installations	0	9	0	10	0	3	0	1	0	23
(f) TOTAL, a + b + c + d + e	2	14	3	16	4	4	1	7	10	41
2. MAJOR WEAPON-MODIFICATIONS										
(a) Implosion-Type Bombs	0	0	0	1	0	2	0	2	0	5
(b) Gun-Type Bombs	1	0	0	0	0	0	0	1	1	1
(c) Other	0	0	0	0	0	0	0	0	0	0
(d) TOTAL, a + b + c	1	0	0	1	0	2	0	3	1	6
3. GRAND TOTAL, 1(f) + 2(d)	3	14	3	17	4	6	1	10	11	47

NOTES:
1. Stage 1 indicates that studies incident to formulation of program are being made.
2. Stage 2 indicates that full-scale design and development is underway.
3. Stage 3A indicates that development is completed or nearly completed, and that action essential to getting into production has been initiated or completed, but first unit has not come off the production line.
4. Stage 3B indicates that production and stockpiling are underway.

The 1950 program, listing 16 categories of research and 22 categories of specific weapons projects, also reflected the President's decision that development of a thermonuclear weapon would be pushed. The LASL plan for 1950 noted:

> "The program proposed ... appears to LASL to be almost the maximum possible effort in the direction of understanding and attaining thermonuclear reactions and, at the same time, to maintain progress in ... fission weapons sufficient to play a real role in the short-range position in this country .... It must also be clear that the general nature and philosophy of the thermonuclear program will differ from those heretofore employed by Los Alamos in its study of fission weapons. Because of experimental and theoretical necessity, and in an attempt to gamble on the chance of maximum progress, tests at Eniwetok involving the expenditure of sizable amounts of fissionable material will take the place of part of the heretofore extensive model testing and detailed theoretical calculation. The more empirical approach can, with great good luck, materially shorten a development period; on the other hand, the chance of failure in such tests will be appreciably higher than that under the old philosophy."

In March 1950, LASL initiated an accelerated program under which most of LASL personnel worked a six-day week through 1951.

By Spring 1951, LASL had perfected an experiment to determine if a fission bomb would generate enough heat to initiate a thermonuclear reaction in liquefied materials. A Greenhouse series test demonstrated the validity of this approach.

Almost immediately following Greenhouse, LASL began development of an experimental device for a large scale thermonuclear detonation or reaction. Perfection of this device required extensive engineering assistance on the device itself by American Car & Foundry Company, and extensive cryogenics assistance by three groups. National Bureau of Standards, in the AEC-built Cryogenics Engineering Laboratory at Boulder, provided engineering research and produced materials required; Cambridge Corporation developed and provided means of transporting the liquids; and Herrick Johnston engineered and built a liquefaction plant on Parry Island. The device was tested in the Fall of 1952, during Operation Ivy.

On the basis of Ivy results and other basic design determinations, shortly after the test there was initiated a comprehensive program for development of DELETED

DELETED

In addition to the three weapons for early test and military use, LASL was developing in mid-1953 other experimental devices to prove new concepts of design. (Other developmental work was also underway after June 1952, in the new Livermore Laboratory.)

Stockpile Operations and Problems ALOO

One of the primary objectives of all SFO operations is the stockpiling of atomic weapons in accord with broad directive schedules and military requirements as these are formulated and issued from time to time by higher authority.

[redacted]

68

[redacted]

Working Relations with DOD

An inspection liaison section had been assigned for the purposes of review and recommendation relative to the DOD interest in specifications and inspection. This section is comprised of military officers who review the specifications presented by Sandia Corporation for AEC approval. The arrangement affords the field office a single point of contact on matters of inspection and specifications wherein coordination with DOD is desired or required.

In the administration of AEC site inspection activities, members of SFOO make periodic liaison visits to ZI sites. Site commanders and staff level officers have assisted the AEC inspection program as requested and/or required.

Distribution of War Reserve Material

On July 1, 1950, the production of War Reserve Material was restricted to Sandia Corporation and Burlington, producing only one type of weapon at any one time. The distribution of the material was to Sites Able, Baker, and Charlie. At that time the distribution was performed by one person in the custodial unit of AEC-Sandia. The material was shipped direct from production immediately in order to build up the stockpile as quickly as possible. This was done primarily to meet military requirements and maximum loads; nearest destination was a secondary consideration.

As this operation progressed through 1951, 1952, and 1953, there were several different types of weapons developed; producers increased from two to four, and sites increased from three to nine, consequently, by 1953, the distribution of War Reserve Material developed into a network system of producers, sites, types of weapons and components, which resulted in a centralized distribution point in order to coordinate the production and shipment of the various weapons and their components to the sites in proper ratio to assure the availability of complete weapons.

This centralized distribution point was reorganized in June 1953, into the Administrative Branch of the field office, and it was necessary to reassign personnel in order to perform this function. This was accomplished by changing the duties of certain personnel in the Branch in order that part time could be spent in the performance of this function.

14. NUCLEAR FIELD TEST OPERATIONS

Testing goes hand in hand with each step in the manufacturing process, from research to stockpile. Laboratory testing is continuous, including, for instance, the tests of the behavior of metals at extreme low temperatures conducted at the Boulder Cryogenics Laboratory in recent years.

ALOO

Both Los Alamos and Sandia have extensive and specialized programs of field testing which do not involve full-scale nuclear detonations. Sandia has its own backyard testing laboratory in the Sandia Base area, a test site at Salton Sea, and uses many other testing sites throughout the United States. These, as discussed previously, range from ballistic, vibration, and static load tests to catapulting and arresting tests, aircraft compatibility, and drop tests of non-nuclear over-all weapons. One of the major reasons for locating Los Alamos Scientific Laboratory on an isolated New Mexico plateau was sparse population and adequate real estate for explosive, but not full-scale nuclear, tests. Several outlying

[redacted]

sites have been used routinely by LASL since 1943 for tests involving high explosives and for tests involving radioactive materials. As discussed in the previous section, much of the requisite knowledge up to the point of disassembly of implosion-type weapons could be tested at Los Alamos' outlying sites. With the advent of two-stage thermonuclear experimentation, however, Los Alamos' outlying sites could no longer be used to acquire assembly knowledge; exploration of both the assembly and disassembly phases now require full-scale field tests.

A majority of full-scale field tests is for exploration of what takes place during assembly and disassembly and for nuclear components research and development. Some are held, however, to check the functioning of various components or of the full weapon. Tests for these purposes are utilized additionally by other national programs, such as military and civil defense effects programs. On occasion, tests are scheduled almost entirely to meet military requirements, but are then used additionally for developmental research.

From the viewpoint of AEC programs, full-scale nuclear field tests are held for the following reasons: To

1. Assure the adequacy of a device or weapon before it enters the national stockpile, to provide a firm basis for undertaking the extensive engineering and fabrication effort which must be expended in order to carry a preliminary model to the version satisfactory for stockpile production.

2. Demonstrate the adequacy, or inadequacy and limitations, of current theoretical approaches in order that promising avenues of development may be exploited more fully or given lower priority of attention.

3. Explore phenomena which can vitally affect the efficiency and performance of an atomic weapon, but which are not susceptible to prior theoretical analysis of sufficient certainty.

4. Provide a basis for choice among existing theoretical methods of weapon improvement in order to concentrate attention along lines of the greatest practical significance.

5. Determine the validity of entirely new and untried principles proposed for application to the production of explosive atomic energy at improved efficiency.

6. Provide entirely new information pertinent to weapons development arising as a by-product of scientific observation of full-scale detonations. Experience has shown the significant value of such incidental information obtained in addition to specifically planned objectives.

7. Gain time in urgent development programs by the substitution of full-scale tests for a portion of a possible but lengthy calculational and experimental program in the laboratory.

ALOO

8. Provide, as a by-product, basic scientific information which becomes a part of the backlog of knowledge more normally obtained in the laboratory. Tests thus contribute to other major phases of weapons development. Another application of this type of information lies in its use in the interpretation from

[redacted]

[redacted]

studies of bomb debris of the constitution and efficiency of nuclear devices detonated by other nations.

Nuclear field tests are thus important and integral factors in the diagnostic phases of the over-all weapons research and development program. They are also essential in providing the National Military Establishment and Federal Civil Defense Administration with pertinent information on effects, and for training purposes of many kinds. The activation of an overseas and a continental proving grounds, and the progressing frequency and number of tests, are a direct reflection of the rapid development of atomic weapons during the period.

Overseas Tests: Pacific Proving Grounds

During the pre-1947 MED period, the first nuclear device was detonated in July 1945, on a remote section of the Alamogordo (New Mexico) Bombing Range. This first, historic test was followed by Operation Crossroads, conducted in July 1946 at Bikini Atoll in the Marshall Islands of the Pacific. The operation consisted of two tests made to determine the effects of atomic weapons against naval vessels. As early as 1947, when the necessity for more tests was apparent, some consideration was given to selecting a testing site within the continental United States. Due to several deterrent factors, the decision was made to continue using the Marshall Islands.

Accordingly, Eniwetok Atoll in the Marshall Islands was approved by the President of the United States on December 2, 1947, as the site for an atomic proving ground entrusted to the AEC for operation and maintenance. Its isolated location and more usable real estate influenced its choice over Bikini. Three devices were tested during Operation Sandstone in April 1948. As a result of the Sandstone tests, the efficiency and flexibility of atomic weapons were substantially increased. Construction of permanent facilities on Eniwetok and Parry Islands began immediately after the operation, and the Pacific Proving Grounds during the present period has served as the overseas site for two series of full-scale tests.

Operation Greenhouse -- Was conducted during April and May 1951. The series consisted of four tests: the detonation of two nuclear weapons (bombs) and two experimental devices. The first shot, a weapon test, was detonated April 8 on a 300-foot tower on Runit Island, Eniwetok Atoll. The second shot, also a weapon test, was detonated April 21 on a 300-foot tower on Engebi Island. The third shot, a device test, was detonated May 9 on a 200-foot, heavy-load tower, on Eberiru Island. The concluding shot, also a device, was fired on a 200-foot tower on Engebi Island, May 25. The objectives of the operation were to prove: a weapon of higher yield and efficiency, a weapon of smaller size and weight, and to conduct explorations in the thermonuclear field. In addition, eight experimental programs to study the effects of nuclear detonations on structures, equipment, materiel, and animals were included for the benefit of DOD, AEC Division of Biology and Medicine, and FCDA. Long range detection techniques were further studied during the operation.

ALOO

Operation Ivy -- Planning was already under way when Greenhouse was concluded. The series was announced on October 1, 1951. The Ivy series consisted of the detonation of a very high yield thermonuclear device, and a high yield nuclear weapon. The first shot was detonated on November 1, 1952, from a surface platform on Elugelab Island. The second shot was an air-dropped weapon detonated at a height of 1,500 feet over Runit Island on November 16, 1952. The test contributed significantly to work in the thermonuclear field. Eleven experimental programs were also included in the Operation.

Continental Tests: Nevada Proving Grounds

As early as 1947, LASL had proposed that AEC activate a continental test site. It was recognized, however, that continental operations would pose difficult problems, including protection of sensitive information, public safety, and public reaction. It was determined that Operation Sandstone would be held overseas and the question of a continental site was postponed.

More frequent tests became essential during 1949 and 1950. LASL required testing at a rate which could not be satisfied overseas. A related test preliminary to Operation Greenhouse was required in 1950 and, with the outbreak of Korean hostilities, LASL renewed its request for a continental site. Studies and site surveys had continued throughout 1948-1950. It was generally agreed that continental tests would be economical of time, manpower, and money. It was finally agreed that, under feasible controls, tests of devices of limited yield could be held with adequate assurance of public safety. Abandonment of Pacific Proving Grounds was never considered, although the possibility that the overseas area might be closed by the international situation was a factor considered. The projected continental site was to be in addition to the overseas test site.

On November 14, 1950, a memorandum from the National Security Council to the Secretary of State, Secretary of Defense, and the Chairman of the Atomic Energy Commission, notified them that the President had directed the Commission, with the assistance of the Department of Defense, to survey suitable continental sites and to recommend one for early development and use.

Five possible areas had been surveyed and the results were re-evaluated:

The Alamogordo-White Sands Guided Missile Range in New Mexico.

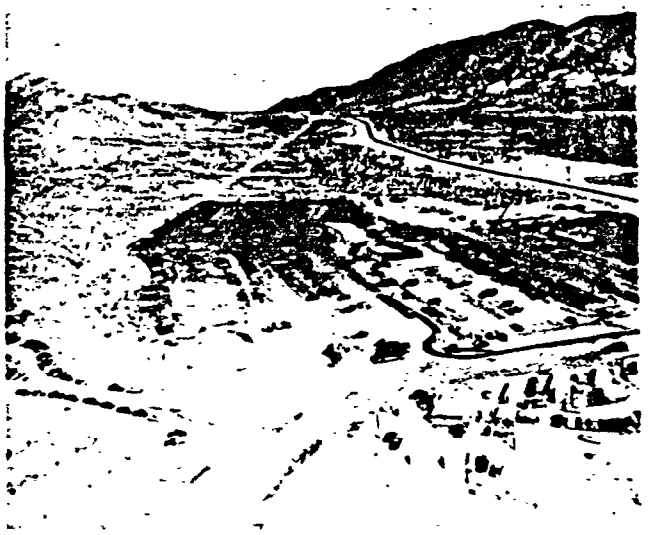
The Dugway Proving Ground, Wendover Bombing Range in Utah.

The Tonopah-Las Vegas Bombing and Aerial Gunnery Range in Nevada.

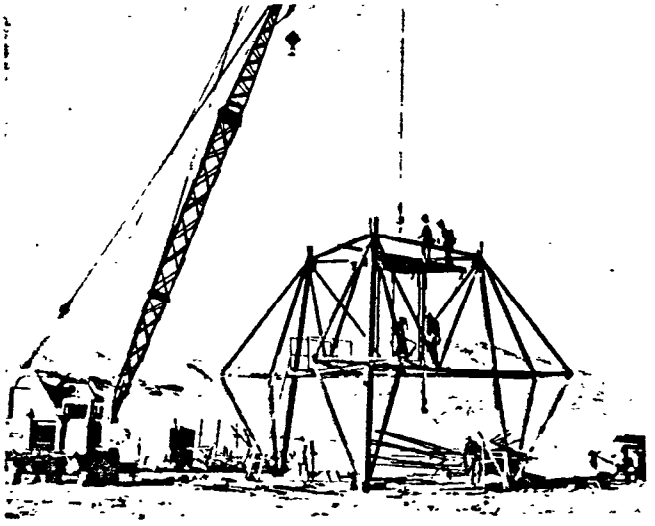
An area in Nevada about 50 miles wide, and extending from Fallon to Eureka.

The Pimlico Sound, Camp Lejeune Area, in North Carolina.

Selection of these possible sites followed elimination of sites in Canada and Alaska; sites along the northeastern coast; and other sites along the southeastern seaboard. Sites in the arid west seemed desirable because they were sufficiently remote from population, and had sufficient surrounding uninhabited areas to allow conduct of nuclear tests with adequate public safety.



Only the Las Vegas area met the criteria for a continental test site: ready accessibility to Los Alamos Scientific Laboratory and Sandia Laboratory by land and air, good communications, adequate radiological safety for small off-site population, satisfactory weather, reasonably regular topography, prospects of economy of preparation and operation, and sufficient real estate.



ALOO

On December 13, 1950, the Chairman, AEC, submitted recommendations for use of the Las Vegas Bombing and Gunnery Range as an atomic continental test site to a Special

ALOO

Horses Injured by Radiological Fallout near
NPG during Upshot-Knothole

[redacted]

Committee of the National Security Council for Atomic Energy Matters. Five days later Presidential approval was given, and preparations were made to activate the site which subsequently became Nevada Proving Grounds.

Continental Test Operations

The Nevada Proving Grounds was activated January 1, 1951, using temporary construction and the first nuclear test shot was detonated on January 27, 1951. During the current three-year period, four series of continental tests have been conducted:

Winter 1951 Series (Operation Ranger)—five shots. All were experimental devices tested by the air drop technique. The tests were diagnostic in nature.

Fall 1951 Series (Buster-Jangle)—seven shots. Five were primarily diagnostic for the benefit of LASL, and two were primarily of interest to DOD as weapons effects experiments. Shot 1 was a tower shot, the following four were air bursts, and the last two were respectively a surface and an underground burst.

Spring 1952 Series (Tumbler-Snapper)—eight shots. They were equally divided as to air bursts and tower shots; five were experimental devices of primary interest to LASL, and three were sponsored by DOD in connection with weapons effects phenomena.

Spring 1953 Series (Upshot-Knothole)—eleven shots, including air, tower, and the 280mm nuclear projectile shot. Nine shots were diagnostic in nature, seven being of primary interest to LASL and two to UCRL; and two tests were of primary concern to DOD, including proof-testing of the 280mm nuclear projectile. The latter, however, was of particular interest to LASL, and justification for the shot was a joint AEC-DOD responsibility.

During the last three series approximately 37,500 personnel of the Armed Forces, including Army, Air Force, and Marine Corps units, were indoctrinated in the principles of atomic warfare through simulated combat maneuvers conducted in conjunction with the tests. Armed Forces participation, "Exercise Desert Rock" I-V, was conducted by the Sixth Army from a headquarters at Camp Desert Rock nearby. Various groups of officer volunteers during several shots were stationed in advance of the main body of troops at the time of detonation. Also exposed to detonation for Armed Forces effects information were materiel and supplies, above- and below-ground structures, and items such as pine trees and railroad equipment.

Air Force participation for crew indoctrination and experimental test purposes as well as for normal air support—such as cloud tracking and sampling—was equally heavy, particularly in the last series. During Shot 9 (1953 series) a maximum of 100 aircraft participated.

Notable from a public relations viewpoint were the two "Open Shots" of April 22, 1952, and March 17, 1953, during which national news media representatives, public officials, and Federal Civil Defense Administration representatives were permitted, under security control conditions, to witness the detonations as uncleared observers. The resulting wide coverage through all media—press, periodical, radio, TV, and motion picture—provided the public with opportunity to add to its understanding of Commission and of Armed Forces activities and objectives. Federal Civil Defense Administration participation in effects experiments was continued throughout the last series, and was reportedly of great value in the national defense effort.

[redacted]

15. CONTROL OF INFORMATION

Control of information on the development and utilization of atomic energy is one of the basic AEC missions under the Atomic Energy Act of 1946. The various related provisions of the Act are defined and interpreted in GM-INF-2, "Policy for Control of Information." Both of these basic papers state firmly that critical information must be protected and then, recognizing the value of the free exchange of ideas and criticisms and the dangers of security blanketing, they state as firmly that non-critical information must be made available to the public. An unusual provision of the Act, Section 3 (a), underlines this by providing that research and development contractual arrangements "shall not contain any provisions or conditions which prevent the dissemination of scientific or technical information, except to the extent such dissemination is prohibited by law."

Four distinct programs have been developed which support the information control objective. Two have as their primary function the protection of classified information (in the sense of all data): Classification and Security. Two have as their primary function assuring that non-critical information is made publicly available: Declassification and Information.

Responsibility and authority for the control of information programs is assigned by the Commission to the General Manager and by him to Operations Managers, these assignments being all-inclusive as part of in-line management except as specifically limited in official papers. Operations Managers may in turn delegate more limited responsibility and authority to their field offices and to contractors.

Washington staff supervision has been assigned by the General Manager to: Office of Classification (including its Declassification Branch), Office of Security, and Division of Information Services. Each has a counterpart, either fulltime or added duty, performing staff supervision in SFOO headquarters and each has a counterpart or is reflected in field offices and contractors.

Summary of SFO's Information Control Programs

Four programs of SFO are concerned directly with the control of information:

The mission of SFO Classification is to determine the weapons information which could be used by inimical interests to the detriment of United States security, and as part of the same process to establish the data which may remain unclassified. A continuing review of both categories is performed to determine if developments require protection for previously-unclassified items, or if protected items may be downgraded to lower classifications or should be considered for declassification.

A primary mission of SFO Security is to protect classified weapons information, assuring that unauthorized persons do not have access to critical data. A related objective is to assure that security fences are not put around unclassified information. The mission goal is expressed in a variety of operations, such as personnel clearance and control, document control, visitor control, and protection of physical property including fissionable materials.

ALCO

[redacted]

[redacted]

The mission of SFO Declassification is to determine if and when previously-protected weapons information may be published without adversely affecting the nation's security. The original mission related only to the declassification of Restricted Data. The present assignment includes, however, declassification action on all categories of classification and has been extended by Washington directive to include some measure of control over photography which is unclassified or over photography in which the Military may have an interest.

The mission of SFO Information is also dual: To withhold classified weapons information from unauthorized persons while encouraging and facilitating the dissemination of non-classified information generally and of classified information to authorized persons to advance the national welfare and satisfy the national interest. Because it is the sole program concerned with putting out material, the balance between Information's two operating objectives should favor dissemination. This balance has seesawed during the past three years with progressive withdrawals of field authority on release of unclassified information while requirements for dissemination were multiplying.

The nature of the weapons manufacturing mission requires that all four programs be conducted in intimate association with the Armed Forces and, to some extent, with other Federal agencies. The four programs' functions are such that they cannot be operated as a fully-delegated field activity; they require detailed, day-to-day coordination with like program divisions in the AEC headquarters. Likewise, the functions may not be fully delegated to field offices and to contractors, requiring detailed, day-to-day coordination between SFOO and its field operators.

It is of interest to note that two of the programs and a major phase of a third are almost exclusively contractor operations. Classification and Declassification are represented at the SFOO staff level and in the field by contractor personnel. Control and dissemination of scientific and technical information is almost exclusively a contractor operation, although some phases of the public release of such information are conducted by the SFOO Information Division and by field offices.

There has been little basic change since mid-1950 in the mission functions of the four programs, Security having perhaps changed most through a searching re-evaluation and clarification of its objectives.

In keeping with the rest of SFO, the requirements—the workload and scope and geography—have been expanded materially.

The all-essential goals common to the four programs are to segregate and to protect critical information and to segregate and encourage dissemination of the non-classified information. During 1947-1950, Classification and Declassification progressed measurably toward information control goals, resulting in a considerable accomplishment in the realistic protection and dissemination of scientific and technical information. Security and Information lagged somewhat in 1950 with too much non-classified material and information being withheld or protected.

AL00

The primary achievement in SFO control of information during the past three years has perhaps been the development of understanding within all four programs of the duality of mission and an integration of attitude and effort. The result has been a sharper definition and a narrower total area requiring protection, permitting better protection. The result has also been a much broader area which did not require the costs and effort of

protection and which could be released safely. The effect on information released publicly has been especially noticeable in the continental test activity, but it has been just as real throughout the research, development, production, community and other management structure of SFO.

Classification

Santa Fe Operations, having the major field responsibility within the AEC for the weapons mission, originates a large volume of data requiring classification. The scope of the activity is indicated by the fact that more than 1,500 formal, written decisions were rendered by the SFO Classification Board during the past three years, and by the Security report that 15,000,000 classified documents have been originated within SFO each year.

In the period since mid-1950, the SFO classification organization has been decentralized to some extent and at the same time formalized as a SFO-wide activity. The position of Dr. Norris E. Bradbury, Director, LASL, as the staff Classification Representative for the Manager, SFO, was made formal and shown on organization charts. Dr. Bradbury serves as Director of the SFO Classification Board with Dr. Ralph Carlisle Smith, Assistant Director for Classification and Security, LASL, as his executive officer in both capacities.

The Manager, SFO, arranged for the appointment of a local classification board at Sandia Laboratory. As a result, the SFO Classification organization as of July 1, 1953, included:

a. The SFO staff Classification Representative: Dr. Bradbury, with Dr. Smith as his executive.

b. The SFO Classification Board: Dr. Bradbury, Director; Dr. Smith, Executive Secretary; and special panels serving as members according to the nature of matters to be considered.

c. The Los Alamos Scientific Laboratory Classification Board: Same as above.

d. The Sandia Laboratory Classification Board: J. R. Townsend, Chairman; William H. Lawrence, Secretary.

Consideration is being given to establishing like boards in other contractor and field office organizations.

Decisions of the local area boards are submitted to the SFO Classification Board for information, or for review and final determination. For uniformity of classification policy and interpretation of existing guides, the SFO Board is the final authority within SFO on all classification matters subject to SFO determination. By this interchange of decisions, the boards have established a more uniform policy and have minimized possible compromises of information. The practice has proved especially valuable in control of information relative to the various high explosives processing plants within SFO.

AL03

A major activity has been providing guidance to the new contractors who have entered into the program including: Dow Chemical, National Bureau of Standards, Procter & Gamble, Thompson Products, Cambridge Corporation, American Car & Foundry, etc.

In his capacity as SFO Classification Executive, Dr. Ralph Carlisle Smith has acted as the classification officer for all weapons test operations, including Operations Greenhouse,

[redacted]

Ivy, Ranger, Buster-Jangle, Tumbler-Snapper, and Upshot-Knothole. In Operation Ivy and the forthcoming Castle, he has been designated not only as classification representative for the AEC but also for the Armed Forces, serving on the staff of the Joint Task Force Commander. In this manner it has been possible to maintain a rather uniform classification policy throughout the weapons and weapons test programs.

Within SFO, a series of classification guides for the several weapons test organizations has been prepared, all of which guides have been approved by the Armed Forces and the AEC. In addition, a few specific guides have been prepared for certain of the contractors because of the peculiar problems involved. These special guides cannot be incorporated entirely within a general guide for the AEC because they take into consideration peculiar circumstances particularly associated with the contractor.

The office of SFO classification representative has maintained detailed and almost continuous contact with the AEC Office of Classification in the preparation of a revised AEC-DOD Classification Guide, a General Classification Guide, a Critical Materials Classification Guide, and in the interpretation of data related to apparent compromise of information.

The Nuclear Weapons Classification Subcommittee, organized mainly of SFO personnel under the leadership of Dr. Alvin C. Graves, has made two major recommendations on information classification which, if adopted, would materially assist SFO activities and result in reduced security costs and no loss or weakening of national security. The first of these is classification recognition that there is no security involved in the approximate yield of nuclear detonations within the continental limits. It is not proposed that these yields should be publicly announced, but that no information should be classified merely because it gives an approximation of such yields. The second recommendation is to adapt to the nuclear weapon program a principle which has been adopted in the reactor field and is now identified as the "black box" idea. This is especially applied to those items of the nuclear weapon which are clearly of a military nature and not essentially an AEC matter, such as the ballistic case and fuzing system for nuclear weapons and the outer case of an aerial bomb, guided missile, artillery projectile, and the like.

Declassification

Dr. Norris E. Bradbury, Director, LASL, in his capacity as Coordinating Organization Director for all activities within SFO, is in direct charge of the SFO Declassification program. Dr. Ralph Carlisle Smith, LASL, is his Executive Officer for declassification.

There is no field organization as such. The individual, contractor, or AEC unit proposing declassification of a report or other material routes it to the Coordinating Organization Director. Field Classification Boards usually provide an advisory opinion to reflect thinking in the operational area immediately concerned.

AL00

The Coordinating Organization Director is advised by Responsible Reviewers, recommended by the Manager, SFO, and appointed by the General Manager, AEC. One member of the LASL staff is also a Senior Reviewer for the AEC and assists on SFO matters as required. Responsible Reviewers are recognized authorities in their respective fields and review documents submitted for declassification which fall within their fields of specialization. Appointment in the 1950-1953 period of Responsible Reviewers at Sandia Laboratory recognized that the work of that laboratory was sufficiently specialized to require specially-trained reviewers in order to expedite the declassification review of specific documents.

[redacted]

To maintain a uniform policy to avoid compromise of program information through declassification of several separate but related items by different organizations, the Director, LASL, and his staff continue to be the channel for forwarding material to AEC Declassification Branch for final action.

During the last three years, there has been a considerable increase in the number of technical items considered for release by Sandia Laboratory. Many of these items have been processed as declassifiable scientific information but might readily fall within the more recent Industrial Information program.

With the policy of classification boards at various field installations, there has been a lesser tendency to overclassify with subsequent declassification required. However, there has been a continuing program to review previously-issued material for downgrading or declassification.

In the three-year period of this report it is estimated that there has been formal declassification on approximately 585 items from LASL and 16 items from Sandia Laboratory. In addition, 34 Los Alamos items have been reduced to Official Use Only. There have not been many items for formal declassification from the other SFO contractors, but it is anticipated that in the future, particularly in view of the Industrial Information program, there will be a sizable quantity of items from them.

The publication of "The Effects of Atomic Weapons" by the Los Alamos Scientific Laboratory early in 1950 and the release of information involved in the Rosenberg-Greenglass cases has made it feasible to consider for public release many items previously considered classified. However, it is recognized fully that on the newer developments the classification of the information might be even stricter than that applied to the wartime and immediately postwar data.

Security

The report of the Office of Security operation is presented separately later in this chapter.

Public and Technical Information

Staff supervision and certain operating functions at the headquarters and the national levels are assigned by the General Manager to the Division of Information Services. Basic assignment in GM-O&M-23, Serial 107, April 24, 1950, is still applicable although there have been various changes not yet formalized in a GM. Organization Chart, DIS, January 21, 1952, is the most recent expression of functions and supporting activities, although it is not current. Similar assignment of both staff supervision and of operating functions, and of supporting activities, prevails in Operations Offices.

ALO9

By organizational division at the Washington level, there are two formal supporting programs: Technical Information and Public Information. Technical Information is concerned with the preparation and official dissemination of classified information and with preparing, controlling, and making publicly available to specialized audiences non-classified scientific, technical and industrial (including management) information; with the industrial (or technological) activity actually being a separate sub-program placed under Technical Information. Public Information is concerned with the controlled public release of scientific, technical, and general information.

DOE/AO

[redacted]

[redacted]

SFO activity encompasses both programs, and through assignments to the SFOO Information Division extends further to sub-programs such as internal information and special projects. Responsibility for staff supervision and for the essential SFOO-level operations are divided between the Director, Information Division, SFOO, and the Assistant Director, LASL, serving essentially as Technical Information Officer for SFOO. Both programs are supported by added duty personnel in field offices and contractor organizations, and by technical or other information personnel in the two weapons laboratories.

The Technical Information Program

This is almost exclusively a contractor activity and one which is presently conducted almost entirely by Los Alamos and Sandia laboratories. Primarily because of its close relationship with declassification procedures, the staff supervision function is performed by LASL's Assistant Director. SFOO Information Division is responsible only for maintaining a degree of awareness of the activity.

Classified Information -- There is a large volume of classified scientific and technical papers and of reports which are distributed throughout the AEC and to some extent to DOD, FCDA, U. S. Weather Bureau, U. S. Public Health Service, etc. The service provided includes: Preparation, coordination and review, and dissemination; and provision of library, document control, and bibliographical services.

Within the Los Alamos Scientific Laboratory there has been an increased effort to put more of its reports into a form so that they will not contain critical weapon data and may be distributed more widely through the AEC classified projects. Title lists of the reports are included with the Laboratory Monthly Report and receive substantial distribution directly to several Armed Forces headquarters. There has been established in LASL a Weapons Test Report Office as a service group for continental and overseas test organizations to provide centralized, expeditious, and uniform handling of weapon test reports. Before this was done, each Joint Task Force had set up a group for handling the reports of its individual operation. Arrangements have been made with the Oak Ridge Extension of Division of Information Services for routine editorial and reproduction services, thus removing the load of reproduction from various field groups and reducing the cost of reproduction of reports through the Government Printing Office. This was accomplished when the workload of the National Nuclear Energy Series was removed from the Oak Ridge extension. It is understood that this avoided the disbanding of an effective organization. About 275 weapons test reports were issued prior to mid-1953.

Sandia Laboratory distributes its reports to a substantial extent within the Department of Defense, such dissemination being facilitated by the close liaison between Sandia and Field Command, AFSWP. The technical reports published by Sandia Corporation cover two broad areas of activity which are conveniently separated into reports covering the development of new weapons, and reports, more properly called manuals, covering storage and use of stockpile weapons.

ALOO

Development reports are prepared by the design groups. There is a series of reports for each development program. The series begins normally with a feasibility study report, which is followed in a normal program by a proposed ordnance characteristic report. The series includes a number of design status reports, culminating in a report entitled "Design Status at Design Release." The final development report is a weapon evaluation report, normally published some months after design release and late enough in the development program to permit a complete evaluation of the weapon's performance and capabilities.

[redacted]

[redacted]

While development reports are written for both the AEC and the DOD, the manuals for stockpile weapons are prepared primarily for the weapon users, the DOD. They include manuals of weapons, weapon assemblies, fuze tests, aircraft loading tests, surveillance, aircraft modification, and handling equipment, assembly and maintenance. They include not only manuals for the assembly, inspection, storage, and use of atomic weapons, but also manuals which serve as catalogs of information and miscellaneous indexes of publication. This large second group of reports is prepared by those most closely in touch with the actual users of the weapons in the field, the military liaison and training organization. The manuals are prepared in close coordination with the groups who train teams to use weapons in the field and with the field engineers of this organization. In this way the manuals' writers are aware of problems which arise in the field and are in a good position to modify manuals rapidly in accordance with changes suggested by field experience.

In both of the large areas of publication, the development schedules and the need for up-to-the-minute information place a premium on meeting tight deadlines.

Other SFO contractors deal almost exclusively with weapons information and hence do not distribute their reports as widely within the AEC organization.

Declassified or Unclassified Technical Information -- The AEC program on non-classified scientific and technical information is primarily not one of public dissemination, but is one of facilitating an individual's dissemination to specialized audiences and of making information available to anyone interested.

Unclassified reports are distributed according to Technical Information Division directive 4500 "Distribution Lists for Non-Classified Reports."

The need to make atomic energy technological information available to American industry was recognized in 1952 with establishment within Technical Information Service in Washington of an Industrial Information Branch. This new sub-program acts primarily to stimulate field organization dissemination of the subject information. It varies from other contractor-operated phases of technical information by assigning final coordination and clearance responsibility within an Operations Office to the AEC information officer. Of the contractors other than LASL and Sandia, Holmes & Narver, support service contractors for Pacific Proving Grounds, has perhaps led in the preparation and dissemination of the industrial type information. The industrial program has not been fully activated within SFOO. It is anticipated that in future years more information now being processed along with scientific information will be separately identified. Three SFO representatives are members of the AEC-wide Industrial Information Committee: Richard G. Elliott, Director of Information, SFOO; Dr. Ralph Carlisle Smith, Assistant Director, LASL; and H. J. Wallis, Superintendent, Staff Services, Sandia Laboratory.

ALO9

In keeping with GM-CLA-2, "Classification Procedures for AEC Research Contractors," there is a continuing flow of information on unclassified areas of research. Specified off-site research requires no reference of information material to higher authority. Specified on-site research may be issued by scientific personnel concerned or published upon authorization by a Laboratory Director. SFOO, for instance, administers a contract with University of California at Los Angeles and the medical school's work is generally unclassified; its reports receive wide dissemination within the AEC and in journal articles.

Public dissemination may be through: an unclassified formal report; a paper in a scientific, professional, or trade journal; a paper with or without visual aids for presentation before a specialized group; etc.

Timetable of Early Thermonuclear Weapons Events

Mk 14

Late 1920's	Discovery made that stellar energy is thermonuclear in character.
Early 1942	Discussion concerning theoretical possibility of starting a thermonuclear reaction with a fission bomb.
7/42	Basic nuclear studies of lightweight elements performed. Theory of "Runaway Super" bomb developed. Extensive work deferred due to press of effort on fission devices.
Postwar	Effort on thermonuclear studies deferred.
1947	"Alarm Clock" device proposed in place of "Super."
8/49	Russian atomic explosion announced.
1/31/50	President Truman directs that effort be continued on thermonuclear designs.
5/8/51	George shot of Operation Greenhouse demonstrates that deuterium and tritium can be made to fuse successfully.
6/19/51	Conference on thermonuclear theory held at the Institute for Advanced Study. (b)(1), (b)(3)
5/22/52	Sandia and Los Alamos propose guidelines for design of thermonuclear weapon to be called the TX-14; emergency-capability committee established.
6/13/52	Joint Chiefs of Staff establish requirement for thermonuclear weapons (b)(1), (b)(3)

9/15/52 Procurement for TX-14 program authorized.

(b)(1), (b)(3)

10/26/53 TX-Theta Committee formed, and holds initial meeting.

2/54 Emergency-capability TX-14's produced.

10/54 TX-14 Bombs retired.

Mk 15

11/28/52

(b)(1), (b)(3)

(b)(1), (b)(3)

4/23/53 Military Liaison Committee requests study of high-yield designs in the 30- to 45-inch-diameter range.

10/12/53 Los Alamos notifies Division of Military Application that TX-15 will be stockpiled by September 1955.

10/26/53

(b)(1), (b)(3)

11/13/53 Proposed military characteristics for TX-15 released by Field Command. Both bomb and warhead planned for production.

1/4/54

(b)(1), (b)(3)

(b)(1), (b)(3)

5/21/54	TX-Theta Committee suggests improvements to the Mod 0.
5/54	Emergency capability TX-17/24 Bombs stockpiled.
11/2/54	TX-17 parachute drop tests started.
11/54	All TX-17/24 emergency-capability units modernized to Mod 0 status.
12/54	Mk 17/24 Mod 1 design released, including inflight insertion mechanism for increased safety, fin of composite metal and plastic, and nuclear improvements.
3/55	Mk 17/24 Mod 1 Bombs enter stockpile.
6/1/55	Mk 17 Mod 2 design released, incorporating contact fuze.
9/55	All Mk 17/24 Mod 0 Bombs converted to Mk 17/24 Mod 1.
8/56	About 25 percent of Mk 17 stockpile converted to Mod 2. Mk 24 Mod 2 program canceled.
10/56	All Mk 24's retired in favor of Mk 36.
8/57	Mk 17 Bombs retired in favor of Mk 36.

hydrogen bomb should or should not be developed, the President directed the Atomic Energy Commission to continue its work on all forms of atomic weapons, including the so-called hydrogen or Super bomb. Work on Super was accordingly accelerated, only to be retarded again in mid-1950 when the outbreak of the Korean War re-emphasized the need for small nuclear devices.

The Air Force made early plans to carry and deliver large and heavy hydrogen bombs and, in 1950, established two projects, Brass Ring and Caucasian. Brass Ring envisioned carriage of the weapon in an unmanned drone B-47, which would be guided to a target by a mother ship and destroyed in the detonation. This project was given considerable support, due to uncertainty concerning the possible yield of a hydrogen bomb, then estimated to lie between 10 and 40 megatons. Project Caucasian involved the logistical support of a bomb containing large amounts of liquified deuterium at low temperatures.[7]

Los Alamos designed a device to test the rapidity with which a mixture of deuterium and tritium would fuse. This test, the Greenhouse George shot, was fired May 8, 1951.

(b)(3)

Edward Teller, one of the original backers of the thermonuclear weapon in 1942, and who had been working on the design in the intervening years, theorized that radiation energy had in some way compressed the deuterium-tritium gas, thus reducing its ignition point and increasing the efficiency of the reaction. This possibility was discussed at a conclave of scientists and AEC representatives June 19, 1951, and it was concluded by the attendees that a practical thermonuclear weapon was achievable, using radiation energy as a compressing force.

Due to some personal differences of opinion, Teller proposed the creation of a new physics laboratory to develop thermonuclear devices. He was supported in this stand by the Air Force, which offered to provide a suitable laboratory. Subsequently, the

AEC established a laboratory at Livermore, California, under the administration of the University of California. The contributions of the University of California Radiation Laboratory to the early development of thermonuclear weapons were somewhat meager, except that the existence of the laboratory helped to encourage the over-all program.

(b)(3)

The computational work involved in analyzing the thermonuclear process was a colossal task, and could not have been accomplished without the great advances in computing equipment that took place in the late 1940's and early 1950's. The IBM 601 was considered quite a machine in 1945, but it was far surpassed by the Maniac, designed at the Institute for Advanced Study, Princeton, New Jersey, and which became available in 1952. A problem that would require 3 months work by the 601 could be solved in 2 days by the Maniac. It is of record that, in the course of running a thermonuclear problem on the Princeton Maniac in 1953, the number of basic arithmetical computations performed was of the same order of magnitude as the total number of similar operations performed at Los Alamos (excluding those done on the Los Alamos Maniac) in the entire 10 years of operation of the Laboratory.

The first task assigned to the Los Alamos Maniac was to perform more exact and extensive calculations of the thermonuclear process.

(b)(1), (b)(3)

Sandia and Los Alamos forwarded a joint letter to the Division of Military Application May 22, 1952, proposing that the TX-14 be designed with the following guidelines:

had established a military requirement for the development of thermonuclear weapons with yields of 1 megaton and over, requesting that these weapons be compatible in size, shape and weight with delivery systems that would be available in 1954. Production facilities for thermonuclear materials would be developed immediately. It was felt that any prior production of a deliverable thermonuclear weapon by the Soviet Union would reduce the existing American lead in weaponry, and that such a shift in balance might well cause a change in Soviet policy. This factor alone provided adequate justification for an approach involving considerable technical risk and a large expenditure of funds.[11]

(b)(1), (b)(3)

Sandia would create a model, to be used in the solution of detailed design problems.[12]

(b)(3)

Some 30 grams of tritium were being produced per year at Hanford, and if all the piles were shifted to the production of this material, 60 grams per year could be turned out.

(b)(3)

thermonuclear weapons.[20] The work of the Committee assumed added importance from the start, as in the meantime the Soviet Union had announced August 12, 1953, that it had detonated a thermonuclear device.

(b)(1), (b)(3)

The capsule was manually placed in the insertion mechanism and cranked into position in the primary by a lever that extended from the nose of the bomb.

(b)(1), (b)(3)

(b)(1), (b)(3)

Meanwhile, other thermonuclear bomb designs had progressed to the point of stockpile entry. Since their yields, nuclear economics, assembly and logistics were better than those of the TX-14, the latter weapons were retired in October 1954.[21] Part of the retired material was used in the Mk 17/24 program.[22]

Mk 15/29

(b)(1), (b)(3)

The Military Liaison Committee wrote to the U. S. Atomic Energy Commission April 23, 1953, stating that the Department of Defense hoped to be able to deliver large-yield weapons by high-performance fighter-bombers and guided missiles.

(b)(1), (b)(3)

A weapon proposal was requested by September 1953, with the prospect of stockpiling any selected designs by late 1955. The Division of Military Application forwarded this letter to Los Alamos, noting that a preliminary statement concerning the TX-15 might help to clarify this design, which apparently had potentialities either as a tactical or strategic weapon, or both.[24]

(b)(1), (b)(3)

(b)(1), (b)(3)

Thus, parachute retardation was not necessary. However, since little would be saved by deleting the parachute, and the parachute might be required by other programs, the design was continued.[30]

A set of proposed military characteristics was released by Field Command November 13, 1953. Inasmuch as some thought had been given to the possibility of making the TX-15 compatible with the Air Force's long-range strategic missiles, such as REDSTONE and SNARK, both a TX-15 Bomb and an XW-15 Warhead were prescribed. Limiting parameters included a diameter of 35 inches, a length of 120 inches, and a weight of 6500 pounds.

The weapon would be required to withstand an altitude of 60,000 feet, temperatures from -65°F to +165°F, and an acceleration of ±10 gravities along the longitudinal axis. Automatic insertion and retraction of the primary capsule within a time cycle of 10 seconds would be possible at any time prior to release of the bomb, and during the missile trajectory except during high acceleration at launch or boost.

The TX-15 should be able to resist, without damage, any forces created by catapulted takeoffs, arrested landings, or normal flight maneuvers. The bomb would be capable of being dropped free fall and, if a high-drag shape was provided, consideration was to be given to the deletion of the drogue parachute.

The fuze should provide a safe-separation time and either air or surface burst.

(b)(1), (b)(3)

A surface burst should provide cleanup detonation in the event of failure of the air-burst fuze.

The ballistic properties of the bomb should be such that either free-fall or retarded trajectories would be predictable and reproducible. Releases were to be possible at all altitudes up to 60,000 feet and aircraft speeds of Mach 0.95. It

(b)(3)

The X-unit would be mounted on the forward face of the primary, and would be repackaged to fit into this space.

(b)(1), (b)(3)

The design of the TX-15 was accordingly accelerated and the TX-13 Bomb canceled.

The possibility of TX-15 missile compatibility was raised again in the March 26, 1954 meeting of the TX-Theta Committee. The SNARK was to be operational in early 1958, but could only carry a warhead weighing up to 7000 pounds. The G-26 NAVAHO would be available in late 1957 and could carry only 4000 pounds, but a G-38 follow-on NAVAHO, operational in 1960, would be able to carry 7800-pound warheads. The REDSTONE, which would be available in late 1957, could carry a warhead of 6900 pounds and, by sacrificing some range, a warhead of 7800 pounds. Since all these applications were some time in the future, the Committee decided that emphasis would continue on the bomb program.[35]

(b)(1), (b)(3)

At the May 21, 1954 meeting of the TX-Theta Committee, Sandia reported difficulties in designing a true contact fuze. This fuze had to be sensitive enough to operate properly in both retarded and free-fall drops, and at the same time be insensitive to rain and hail, as well as shock caused by detonation of antiaircraft shells. The TX-15 secondary was in the front end of the weapon, and thus would be physically damaged soon after weapon contact with the terrain.[36] The Committee concluded that a satisfactory contact fuze could not be developed for the TX-15 within the time scales of the weapon, and that the proximity fuze should be used.

Report SC3390(Tr), Proposed Ordnance Characteristics for the TX-15 Weapon, was discussed at the June 30, 1954 meeting of the Special Weapons Development Board.

(b)(3)

The TX-15 was 34-1/2 inches in diameter, 130 inches long, and weighed 7500 pounds.

(b)(1), (b)(3)

Pullout switches closed at release of the bomb from the aircraft, and battery power started operation of the inverters. After the safe-separation interval timer completed its cycle, the X-unit could be charged by closure of the arming baro. When the detonation altitude was reached, the firing baro closed, connecting the output of the X-unit to the detonators.

(b)(3)

The weapon would be stored in a completely assembled condition, less power supply and primary capsule. The only disassembly permitted would be for inspection of firing set, detonators and interconnecting cables, and a surveillance break was provided for this purpose just forward of the primary. Since the program was urgent, and since any prospective missile carriers were still far in the future, the TX-15 was restricted to bomb application.[38] Field Command suggested that the weapon case be sealed, to provide protection against its environment, and Sandia provided internal seals for all case joints..

(b)(3)

The Mk 15 Mod 0 Bomb was design-released in October 1954. Four major changes had been made since the Proposed Ordnance Characteristics had been issued. One was the sealing of the weapon case. Plastic liners between the inside of the case and the exterior of the secondary were replaced by liners made of rubber. This change eliminated machining and resulted in a more closely controlled product.

(b)(3)

The bomb was stockpiled April 1955.

A proximity fuze was incorporated in the production weapons.

(b)(1), (b)(3)

(b)(1), (b)(3)

Radar antennas were installed in the bomb fins, where they gave good coverage, not only straight ahead of the bomb but to the side. This caused detonation if the Mk 15 dropped close to the side of a building.[40]

Subsequent component testing for temperature, humidity, pressure, vibration, shock, dust and salt spray showed that all components, with some few exceptions, could satisfactorily withstand these environments. In the few exceptions, it was decided that the item would never experience the condition prescribed. Environmental tests were performed on six complete weapons, and included cycles of artic, desert and tropical conditions. These tests were successfully passed, as were various dynamic tests. Flyaround tests were conducted in a B-47, to detect any adverse vibrational frequency ranges, and the weapon was catapulted in an A3J. Drop-tower tests simulated the maximum loads on the bomb caused by carriage in various aircraft. The weapon was dropped from a height of 20 inches onto a concrete platform, propelled down a ramp and into a wall, and subjected to standard railway humping tests. The full-scale drop program included 11 ballistic and 22 fuzing and firing drops. To create extreme release conditions, two drops were accelerated by jato boosters.

Consideration again turned to the problem of developing a missile warhead, and a thorough discussion was held in a joint meeting of the TX-Theta and TX-N Committees on January 6, 1955. The design was still too heavy, but it was felt that perhaps 800 pounds might be shaved off the weight by reducing the thickness of the aluminum case.[41]

Some attention was given to carriage of the XW-15 on the F-101 aircraft. The project would have required a streamlined shape for external carriage known as Shape 96.[42] However, the program was later canceled.

Meetings had meanwhile been held at Redstone Arsenal to discuss installation of a warhead in the REDSTONE missile.

(b)(3)

(b)(1), (b)(3)

The missiles were the Army's REDSTONE and the Air Force's SNARK and NAVAHO.[45, 46]

Development requirements for the installation of a Mk 15 Warhead in the Pod of the B-58 or Hustler airplane were established and, during 1955, the program was alternately canceled and revived.[47] By the end of the year, however, it had been decided to delete all applications of the Mk 15 Warhead, and to use the Mk 39 weapon.[48]

Meanwhile, work had been proceeding on the development of true contact fuzing for the Mk 15 Bomb, with several possible methods being studied. The use of probes, both fixed and extendible, was discarded, as it was found that too much of the weapon area was left insensitive to impact. A design using a double shell, having laminated layers of insulator and contact material which would crush on contact, was found to be overly sensitive to antiaircraft fire.

(b)(1), (b)(3)

The most practical method appeared to be the use of barium titanate crystals which, under pressure, produced a pulse of energy. Development of this device resulted in good reliability and high performance. Thermal-cell batteries would replace the nickel-cadmium units, and required no preparation or maintenance.[49]

A proposal was made that this new fuze be applied to Mk 15 weapons that would have only a bomb capability (at that time, the warhead application was still being considered).[50]

(b)(1), (b)(3)

Requirements for these programs had been generated by a letter from the Secretary for Defense dated May 3, 1955.

The Military Liaison Committee had meanwhile become concerned that a lightweight bomb would require quite different handling equipment than that provided for the Mk 15 Mod 0, and suggested that new nomenclature be assigned.[47] Thus, on December 2, 1955, the Division of Military Application redesignated the Mk 15 modification program of weight reduction, contact fuzing, and thermal battery, s the TX-39. The Mk 15 modification of [54] contact fuzing and thermal battery alone would be the Mk 15 Mod 1 Bomb. This latter program was later canceled when it was found that the production complex could not deliver enough critical components to support all the using programs.

(b)(1), (b)(3)

A trajectory arm switch was added to the fuzing system to prevent power from reaching the X-unit until the bomb had experienced a normal release.[55] These changes were incorporated in the Mk 15 Mod 2 Bomb which entered stockpile in March 1957.

TX-29

(b)(1), (b)(3)

Early in 1954, a feasibility study of the warhead was authorized for use with the NAVAHO, a supersonic, surface-to-surface, pilotless bomber (as the missiles were called in those days), capable of striking targets at ranges up to 3500 nautical miles.[56]

(b)(1), (b)(3)

Subsequently, the Division of Military Application notified the Military Liaison Committee March 16, 1955, that it appeared better to proceed with modifications to the Mk 15 program, which would provide a lighter case and a contact fuze, than to continue with work on the TX-29.[58]

It was pointed out that a completely new design, such as the TX-29, might provide a slightly increased yield over the Mk 15 design.

(b)(1), (b)(3)

The program was subsequently canceled by the Division of Military Application August 25, 1955.[52]

TX-16

(b)(3)

This was analogous to holding a lighted match under a large block of wood for a few seconds--not long enough for the wood to catch fire.

(b)(3)

However, the lack of a high-capacity, high-speed computer to perform the necessary extensive calculations hampered this approach.

(b)(1), (b)(3)

(b)(3)

Mk 17/24

(b)(1), (b)(3)

It was noted that the yield of such a device was thoroughly uncertain, but that it was quite unlikely to be of weapons interest.[2]

Subsequently, more confidence was developed in this design, and it was assigned a nomenclature of TX-17.[67] Sandia would be responsible for the design and production of the afterbody, fuze power supply, parachute and pertinent test and handling equipment. The TX-14 baro fuze would be used in the early weapons but be replaced by a proximity fuze as soon as possible.[68]

(b)(1), (b)(3)

(b)(1), (b)(3)

The Mk 17/24 Mod 1 was design-released December 1954 and appeared in stockpile March 1955. By September 1955, all the Mod 0's in stockpile had been converted to the Mod 1 configuration.[22]

In the meantime, work had been proceeding on the design of a proximity fuze, but many difficulties had been encountered.[81] Additionally, the Military--and especially the Strategic Air Command--had developed increasing interest in true contact bursts, to be used for cratering enemy air fields. Sandia thus decided to design a true contact-burst fuze, and to apply this initially to the Mk 17/24 weapons. /

(b)(3)

/The initial approach was to design a contact fuze that would operate against hard, flat targets, with the bomb striking in a nearly vertical position. Tests would then be made to discover how far the fuze could be extended for more severe impact conditions.[82]

It was relatively simple to design contact fuzes for fission weapons, since these devices were covered with a light ballistic fairing that was able to sense the shock of impact and signal detonation before any real physical damage was done to the weapon. However, in thermonuclear devices, the heavy case would have to sense the impending shock and detonate just before actual impact took place.

Discussions with Los Alamos led to the conclusion that the secondary reaction would occur if the primary reaction was completed, and it was decided to use a barium titanate crystal contact fuzing system developed for fission bombs.[83] Sandia performed some sled tests in Area III, from which a design was evolved using two networks each containing two impact crystals, mounted on the nose of the bomb. A fast-firing gap-type X-unit was concurrently developed.

Further work on parachutes was necessary, in order to produce a design which would permit releases from B-52 bombers and result in a down-time of 75 seconds. Sandia placed an order on Wright Air Development Center for both standard and heavy-duty parachutes with diameters of 40 feet. The first phase of this testing program was completed January 19, 1955, after eight drops had been made with standard chutes. Test results showed that opening shocks were lower than expected. However, the requirement for carriage in the B-52 was canceled April 24, 1956, due to release troubles in which the suspension sling failed to retract properly. Subsequently, the Strategic Air Command decided to use a 64-foot-diameter chute and to place an operational restriction of 365 knots airspeed and 20,000-foot altitude on the weapon at release.

The Mk 17/24 Mod 2 Bomb was design-released June 1, 1955. The weapon contained a Mk 17 Mod 0 Fuze, with both contact- and air-burst capabilities. The bomb was 61.4 inches in diameter, 298 inches long, and weighed 42,000 pounds.

(b)(1), (b)(3)

The fuzing operation could be selected by a control in the bomber before weapon release.

(b)(3)

The weapon could be stored for 18 months under stockpile storage

(b)(1), (b)(3)

Teapot -- A less-than-full-scale test series held at the Nevada Test Site. Series of 14 tests, starting February 18 and ending May 15, 1955.

Thermal Battery -- A battery whose electrolyte is in a solid state while inactive. To activate, heat is applied to this electrolyte, melting it and putting the battery into active output condition.

Thermonuclear -- Two-stage reaction, with a fission device exploding and starting a fusion reaction in light elements.

Ton (Yield) -- A means of measuring the yield of an atomic bomb by comparing its output with the effect of an explosion of TNT. A 1-ton yield is equivalent to the detonation effect of 2000 pounds of high explosive.

Tritium -- The hydrogen isotope of mass number 3.

Two-Stage -- Combination of fission and fusion action in a weapon.

TX-N Committee -- A joint committee of Los Alamos Scientific Laboratory and Sandia members, established to guide the development of implosion-type weapons.

TX-Theta Committee -- A committee established to guide the development of thermonuclear weapons.

University of California Radiation Laboratory -- A laboratory established under the guidance of the University of California to work on thermonuclear designs, and located at Livermore, California. The laboratory was founded largely as the result of the interest of Dr. Edward Teller in pursuing thermonuclear work.

Upshot-Knothole -- Tests of atomic devices, held at the Nevada Test Site. Series of 11 shots, starting March 17 and ending June 4, 1953.

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent of uranium-238; the rest is uranium-235.

Wooden Bomb -- A weapon designed to have an infinite shelf life and to require no special storage or surveillance. "As trouble-free as a block of pine."

X-Unit -- ~~A high-voltage transformer.~~ A device used to furnish high voltage to the weapon detonators.

Yaw -- Motion of the bomb as it falls through the air, such that it alternately veers left and right.

Yield -- ~~A means of~~ measuring the effect of a nuclear detonation ~~by~~ comparing it to ~~with~~ the effect of an explosion of TNT. By definition one kiloton is 10^{12} calories.

Yucca Lake Range -- A test range located at Yucca Lake, Nevada.

(b)(3)

MK 21/~~26~~ 36

(b)(1), (b)(3)

The Mk 17 weighed over 21 tons and consequently was difficult to transport and handle.

(b)(1), (b)(3)

It had a diameter of 60 inches and a length of 145 inches (both dimensions controlled by the size of existing aircraft bomb bays), and a weight of 20,000 pounds.[1]

(b)(1), (b)(3)

The committee proposed that if the test was successful, the device be weaponized, and assigned nomenclature of TX-21 to the program.[2,3]

(b)(1), (b)(3)

Sandia meanwhile had started scale studies of the TX-21 shape and, by early March 1954, had determined that it would require at least one spoiler band on the nose and another on the afterbody to produce adequate free-fall stability. It was thought that a flat area on the nose might eliminate the need for a nose band, and appropriate tests were scheduled. It was estimated that external dimensions could be definitely fixed by mid-1954; fuzing, firing and ballistic drop tests held in early 1955; design release effected in mid-1955; and early Mark production by January 1956.[5]

The weight of the bomb was discussed in the March 26, 1954 meeting of the TX-Theta Committee. (b)(3) This would allow the weapon to be delivered by the B-58 or Hustler bomber, then being designed. Los Alamos stated that any weight-reduction study would delay the overall program, and noted that bombers could refuel in the air after takeoff. There would thus be little difference in bomber range due to weapon weight.

After discussion, the Committee decided that an attempt would be made to trim the weight to 15,000 pounds. Sandia would test wind-tunnel models representing diameters between 48 and 54.5 inches, and would study the component space problems created by such diameters. It was requested that this investigation delay the program not more than one month.[6]

The military characteristics for a two-stage weapon in the 23,000-pound maximum weight class were released April 15, 1954.

(b)(1), (b)(3) It was stated that more than one ballistic shape might be required for these various applications, but that the number of such shapes should be held to a minimum.

(b)(1), (b)(3)

The bomb was to be capable of being released either free fall or retarded as inflight-selectable options. Remotely controlled automatic nuclear arming and safing would be possible at any time prior to release of the bomb from the aircraft. A safe-separation time should be provided, and the weapon was to be able to provide either air burst or surface burst, with the latter feature acting as cleanup in the event of malfunction of the air-burst option. The burst height would be settable prior to flight. Any power source provided would have a storage life of from 2 to 5 years, require no preflight preparation beyond installation in the bomb, and no activation other than weapon release. The battery life after installation was to be at least equal to the time interval between normally scheduled inspections of the assembled bomb.[7]

It was felt that the TX-21 might have a diameter of 47.5 inches, a length of 147 inches in the parachute-retarded version, and would weigh between 15,000 and 16,000 pounds. The bomb would be compatible with the aircraft specified in the military characteristics.

(b)(1), (b)(3)

The parachute could be reefed for shorter times of fall. The air-burst fuze would be timer-armed and baro-fired.[8]

The results of wind-tunnel experiments now became available and were discussed in the April 23, 1954 meeting of the TX-Theta Committee. The tests had been made at a speed of Mach 0.93 on models with scale diameters of 48, 51, 52 and 54.44 inches. A quarter-caliber ogive nose had produced poor results. A hemispherical nose with a 0.4-caliber flat had resulted in fair dynamic stability with no spoiler bands, and good stability with one band located between Stations 77 and 103. Good pressure-sensing results had been secured, and more testing was scheduled.

Sandia noted that the ready-weapon philosophy adopted for the TX-15 would also be used for the TX-21. A sealed storage container would be provided and the

weapon would be packaged in this container with fins attached and fuze installed. Most of the bomb would thus be assembled, and a minimum of strike assembly checks would be required during a ready-weapon life of 90 days.[9]

By the April 28, 1954 meeting of the Special Weapons Development Board, the diameter of the TX-21 had been increased to 52 inches, as it was desired to provide the largest weapon that could be carried by the B-47, the weapon's primary carrier.

(b)(3)

It was found that the P6M aircraft might subject the bomb to a vertical acceleration of 7.5 g's, and this might degrade the weapon's reliability. Additionally, the weapon fins would have to be relocated to allow the bomb to fit the rotating bomb-bay door of the P6M.[10] It was decided to concentrate on B-47 compatibility, and to consider application to other bombers at a later date.[11]

Additional discussion was held in the May 21, 1954 meeting of the TX-Theta Committee. Los Alamos was concerned that the weapon's efficiency might be sacrificed by an effort to reduce weight, and it was felt unwise to release any light design for stockpiling without proof tests

(b)(1), (b)(3)

Sandia noted that this change would require a new series of wind-tunnel tests. The final decision was to allow a weight increase, as the B-47 would have to refuel after takeoff with a 15,000 pound bomb, and the aircraft range would not be greatly affected by the heavier bomb weight.[12]

Scale model tests were conducted at the Cornell Wind Tunnel May 26-27, 1954, and discussed in the June 4, 1954 meeting of the TX-Theta Committee. Ten nose shapes had been tested, and the best results were obtained from a hemispherical nose with a half-caliber flat.

(b)(1), (b)(3)

The two weapons would have a near-contact burst as the primary option, achieved by a network of proximity fuzes, and these units would provide backup for the secondary air-burst option. The fuzing and firing systems in both options would be armed by a barometric switch. A true contact fuze for thermonuclear applications was being developed, but this design would require extensive testing.

Work was progressing on improved types of power sources, which would meet military requirements of minimum preparation time and long storage life; but nickel-cadmium batteries would be used in the early stockpiled weapons. A retarded trajectory was desired, due to the large yield of the weapon, and would be provided by a 24-foot-diameter parachute, reefed to provide a down-time of 75 seconds, as compared to an unreefed time-of-fall of 108 seconds. Use of this parachute would be controlled by equipment installed in the aircraft.

It was noted that the diameter of the bomb over the spoiler bands was 58.47 inches, the overall length was 148.37 inches, and the weight was 17,600 pounds.[20] The outer case was an aluminum-alloy shell which formed the main structural member of the bomb.

(b)(1), (b)(3)

The afterbody was a cylindrical extension of the warhead case, having the same diameter and being attached to it by an external bolting flange which also served as an aerodynamic spoiler band. Access doors were provided for battery installation, safety switch, and interconnecting box. All fuzing and firing components, with the exception of X-unit and pullout switch, were mounted on a plate readily accessible through the tail of the bomb after the parachute container was removed.

The bomb had four fins, with a 6- to 14-degree double-wedge shape, a 39-1/2-inch chord length, and an 80.9-inch span. The forward half of each fin was of sheet metal and the remainder of polyester-glass laminate. A proximity-fuze antenna was installed in the plastic portion of each fin.

Deployment of the 24-foot-diameter parachute could be selected at any time prior to weapon release. Fuzing and firing system components were the same as the TX-15 Bomb, with the exception of X-unit and cabling. A remote-setting baroswitch provided a detonation signal for air bursts, and a network of four proximity fuzes provided the signal for near-contact bursts, as well as cleanup for air-burst failures. Safe separation was provided by a baroswitch that was set prior to takeoff of the strike bomber.[21]

The Division of Military Application notified the Military Liaison Committee October 25, 1954, that the TX-21 would be design-released in March 1955, with stockpile entry in August 1955. To meet this schedule, it had been necessary to assign the highest priority to the development.

(b)(1), (b)(3)

Report SC3608(TR), Design and Description Report at Design Release of the Mk 21/26 Mod 0 Bomb, was reviewed in the June 1, 1955 meeting of the Special Weapons Development Board. The bomb was 58.48 inches in diameter over the spoiler bands, and 149.6 inches long. (b)(1), (b)(3)

Either free-fall or parachute-retarded deliveries were possible. A 16-foot parachute furnished a 75-second time-of-fall.

The drop-test program was still under way, with nine ballistic and three fuzing and firing drops completed. Ballistic performance was satisfactory, but some parachute oscillations had been noted, and this problem was being solved as the test program progressed.

(b)(1), (b)(3)

This required an increased aircraft escape time of 100 seconds, and Wright Air Development Center was requested to develop a 24-foot-diameter parachute. It was felt that a two-stage deployment system would have to be used to mitigate the opening shock of the larger canopy.[33]

Report SC3694(TR), Engineering Evaluation of the Mk 21 Mod 0 Weapon, was presented to the December 14, 1955 meeting of the Special Weapons Development Board. Environmental resistance had been determined by component testing to performance standards, as well as overall weapon testing in arctic, tropic and desert environments. Models had been subjected to thermal tests; tests simulating loads involved in flights of B-47 and P6M aircraft; railroad humping tests; and rain, sand, dust, salt spray and sunshine tests. A total of 42 units had been drop-tested, including ballistic free-fall units, ballistic parachute units with proximity fuzes, ballistic parachute units with contact fuzes, and fuzing and firing units.

(b)(1), (b)(3)

Based on the testing program, it was believed that the weapon design imposed no operational limitations within the stockpile-to-target sequence and that the bomb met the military characteristics with the exception of the following: (1) The weapon weighed 17,500 pounds instead of the desired 15,000 pounds; (2) nickel-cadmium, rather than thermal, batteries were used; (3)

(b)(1), (b)(3)

and (4) the parachute design did not meet the military characteristics. Work was continuing in an effort to improve the last two points.

(b)(1), (b)(3)

Parachutes had to be inspected and repacked every 3 months, and drop aircraft were not to exceed a release velocity of 400 knots. On September 24, 1956, this release velocity was increased to 500 knots; and on July 12, 1957, a general release, with no limitations, was issued.[35, 36]

The sequence of events in the fuzing and firing sequence was as follows: ~~For the~~ For the air-burst option, either free-fall or parachute-retarded option could be selected. The arm baroswitch was set at the desired arming altitude prior to takeoff of the bomber. During flight to the target area, power was applied to the battery heaters, the firing baroswitch was set to the selected altitude, the nuclear capsule was remotely inserted, and the safing switch was armed.

When the bomb was released, withdrawal of the arming wires closed the pullout switch and supplied power to the fuze. The inverters started operation and,

after the safe-separation interval (determined by the setting of the arm baro-switch), the X-unit started to charge and the proximity fuzes were armed. A 3-second delay was provided by a timing device to prevent firing before the X-unit attained its normal charge.

As the bomb reached the desired burst altitude, the firing baroswitch closed, actuating the firing switch in the X-unit, discharging the capacitor bank into the detonator bridge wires, and initiating the explosive and nuclear sequence. If the system malfunctioned, the proximity fuze detonated the bomb. The parachute was deployed after release from the aircraft, if the retarded option had been selected. If a near-surface burst was selected, the barometric fuze was set at -3000 feet and the proximity fuze detonated the weapon.

(b)(1), (b)(3)

The Mk 21 Mod 0 first appeared in stockpile December 1955, and final deliveries were made in July 1956.

(b)(1), (b)(3)

The TX-26 was never authorized for production.[38]

Meanwhile, work had been proceeding on the design of a true contact fuze.[39] Report SC3606(TR), Proposed Electrical Characteristics for the Fuzing and Warhead Systems for the TX-15-X1 and the TX-21/26-X1 Weapons, was presented to the April 27, 1955 meeting of the Special Weapons Development Board.

(b)(1), (b)(3)

(b)(1), (b)(3)

Four methods of producing contact bursts had been considered. The first was the use of nose probes, both fixed and extendible. Study showed that this system was not ideal, since much of the weapon was left insensitive to impact. A second possibility was the use of an insulated double shell, which would crush on contact and produce a firing signal. This was a one-shot type of device, and was very sensitive to antiaircraft fire. A third method was the use of low-burst (1- to 25-foot) proximity fuzes, but these required further development. The fourth was use of barium titanate crystals, and appeared the most promising.

(b)(1), (b)(3)

The contact fuze was discussed in the June 1, 1955 meeting of the Special Weapons Development Board when Report SC3607(TR), Proposed Ordnance Characteristics for the TX-21/26-X1 Weapon, was presented. The report noted that four contact crystals would be mounted on the nose of the bomb and a fast-firing X-unit installed. The modified design would be released in February 1956 and Mark units produced by late 1956.[32]

During the development drop program of the TX-21-X1, data were obtained that caused concern over the operation of the contact crystal fuzing network.

(b)(1), (b)(3)

A joint letter from Sandia and Los Alamos was forwarded to the Santa Fe Operations Office June 19, 1956. This noted that the possibility of providing a boosted, externally initiated primary had been studied.

(b)(1), (b)(3)

Field Command notified Albuquerque Operations November 1, 1956, that the Mk 21 handling equipment caused spalling of concrete floors in storage igloos. This was due to the hard casters of the weapon bolster, and development of a suitable wishbone trailer was requested.[46] Sandia subsequently designed and produced a prototype device incorporating rubber tires.[47]

All Mk 21 Bombs were withdrawn from stockpile in the period June through November 1957, and were converted into Mk 36Y1 Mod 1's.[38]

(b)(1), (b)(3)

TX-22 Cross-Section

Timetable of TX-22 Events

9/18/53 (b)(1), (b)(3)

10/29/53 Santa Fe Operations Office authorizes Sandia to assist in the above design.

2/2/54

(b)(1), (b)(3)

4/30/54

TX-22

(b)(1), (b)(3)

Sandia was requested to develop preliminary ballistic configurations, as well as requisite parachute ~~and~~ and fuzing and firing components.[48]

(b)(1), (b)(3)

The Santa Fe Operations Office requested Sandia, October 29, 1953, to assist the Radiation Laboratory in work on the aerodynamic case. Sandia would also design the fuzing and firing system, and conduct flight tests for both ballistics and systems prove-out.[49]

A review of a prospective drop-test program was held November 19, 1953. The devices would be released from a B-36 bomber flying at an altitude of 40,000 feet.

(b)(1), (b)(3)

The question of parachute retardation was raised, and was subsequently referred to the Air Force Special Weapons Center.

(b)(1), (b)(3)

(b)(1), (b)(3)

However, the Santa Fe Operations Office, in a letter dated March 17, 1954, stated that any ballistic or fuzing and firing work on this design would be of minimal value, since the weaponized version would probably differ greatly from the test device. It was suggested that plans be made to hold the test on a barge, thus obviating the need for case design.[57]

(b)(1), (b)(3)

Timetable of Mk 36 Events

11/22/55	(b)(1), (b)(3)
1/3/56	TX-36-X1 design released.
4/56	Mk 36 Mod 0 enters stockpile.
5/56	Mk 21/36 Mod 1 Bomb design released.
7/13/56	TX-36-X2 program authorized for development.
9/24/56	(b)(1), (b)(3)
10/24/56	Proposed ordnance characteristics of TX-36-X2 Bomb reviewed by Special Weapons Development Board.
10/56	Mk 21/36 Mod 1 Bomb enters stockpile.
11/15/56	(b)(1), (b)(3)
4/12/57	TX-36-X2 program suspended.
4/22/57	(b)(1), (b)(3)
7/11/57	Resumption of work on TX-36-X2 authorized.
7/57	(b)(1), (b)(3)
4/23/58	TX-36-X2 design released.
1/9/59	Albuquerque Operations Office cancels Mk 36 programs.

Mk 36

(b)(1), (b)(3)

The TX-21-X1 program was subsequently canceled, but the TX-36-X1 was design-released January 3, 1956, and became, in production, the Mk 36 Mod 0.[63, 64] The weapon entered stockpile in April 1956 with a proximity fuze and internal initiator.[38]

Meanwhile, other improvements in the Mk 21 design had been suggested, principally in the fuzing and firing system. This work had begun in early 1955 in connection with the Mk 15 and Mk 39 programs, and the proposed design would provide options of either air burst or true contact firing. The weapon would be armed and fired by barometric switches, and the contact crystals would act either as primary fuze or as backup to the air-burst system. Thermal batteries would replace the nickel-cadmium units and would supply both low-voltage power for the fuzing system and high-voltage power for charging the X-unit.

Report SC3826(TR), Design and Description Report at Design Release of the Mk 21/36 Mod 1 Bomb, was released May 1956. This noted that the yield, weight, and

physical configuration of the Mod 1 was essentially identical with the Mod 0, with the exception of the fuzing and firing system. The Mod 1 would be employed in a high-altitude level release, using either a free-fall or retarded trajectory.

(b)(1), (b)(3)

Baroswitch settings were made on the ground prior to aircraft takeoff by a single dial setting. This setting was computed by comparing the intended height of burst with the target elevation above sea level and including a 300-foot offset correction. Prior to bomb release from the strike aircraft, the selector switch was placed at either air- or ground-burst position, the nuclear capsule inserted, the safing switch placed in the armed position, and the option switch placed at either the open or closed position, depending on whether ground or air burst had been selected.

The release of the bomb from the aircraft closed a pullout switch in the high-voltage-battery firing circuits, and operated magneto generators which furnished electrical pulses to ignite the low-voltage batteries. Power from these batteries was applied to the open contacts of the arm baroswitch. When the arm baroswitch closed, at the appropriate point in the weapon trajectory, low-voltage power was applied through the closed pullout switch and safing switch to the activating circuits of the high-voltage batteries, placing these latter devices in operating condition. The 2500 volts provided by these batteries charged the X-unit and supplied plate voltage to the trigger circuit.

If air-burst option had been selected, closure of the firing baroswitch applied a signal from the low-voltage batteries to the trigger circuit, thus detonating the bomb. If ground-burst option had been selected, the option switch held the firing circuit open, allowing the weapon to fall to the ground, where the contact fuze supplied the detonation signal.[65]

The Mk 21 Mod 1 Bomb was never produced, but the Mk 36 Mod 1 design entered stockpile in October 1956.

(b)(1), (b)(3)

(b)(1), (b)(3)

/The TX-36-X2 would be design-released in June 1957 with early production scheduled for July 1958 and operational availability in the fall of 1958.[69]

(b)(1), (b)(3)

(b)(1), (b)(3) Albuquerque Operations Office replied February 13, 1957, noting that Sandia and Los Alamos would issue a joint reply after TX Committee meeting of February 21, 1957.

(b)(3)

The Division of Military Application replied that these rates could not be currently established, as no production directive had been released.

(b)(1), (b)(3)

Subsequently, April 12, 1957, all activity on the TX-36-X2 program was suspended by the Albuquerque Operations Office, based on an expectation that the program would be canceled.[76]

(b)(1), (b)(3)

Sandia was requested to prepare a product definition as soon as possible.[77]

Sandia wrote to the Albuquerque Operations Office May 3, 1957, proposing that nomenclature for the Mk 36 Mod 1 Bomb include the designations Y1 and Y2.[78]

(b)(1), (b)(3)

The foregoing was forwarded to the Division of Military Application February 17, 1958, with a production recommendation. It was noted that the design would provide safety features that had been suggested by the Air Force Special Weapons Center and that the modification could be completed by September 1959.[85]

The Division of Military Application sent a teletype to the Albuquerque Operations Office April 10, 1958, authorizing modification of some Mk 36 Mod 1/Y1 and Y2 Bombs to the TX 36-X3 configuration.[86] This program had been approved by the Military Liaison Committee, which agreed that weapon safety would be thereby materially increased.[87]

Report SC4146(TR), Description and Status at Complete Design Release of the TX-36Y1-X2 Bomb, was presented to the April 23, 1958, meeting of the Special Weapons Development Board and subsequently released in May 1958.

(b)(1), (b)(3)

The design had been authorized for development July 13, 1956, suspended April 12, 1957, and work resumed July 11, 1957.

(b)(1), (b)(3)

A new fuzing and firing system was provided, but the contact fuze was retained.

(b)(3)

(b)(3)

Report SC4222(TR), Final Evaluation of the Mk 36Y2 Mod 1 Bomb, was presented to the December 17, 1958, meeting of the Special Weapons Development Board.

(b)(1), (b)(3)

(b)(1), (b)(3)

Dynamic drop tests to ultimate loads, railroad humping tests, extreme temperature tests, and a simulated 6-month tropic storage test had been conducted, and these demonstrated the ability of the weapon to withstand these environments.[89]

At the above Board meeting, Report SC4188(TR), Final Evaluation of the Mk 36Y1 Mod 2 Bomb, was also presented.

(b)(1), (b)(3)

About half the existing stockpile of Mk 36Y1 Mod 1 Bombs would be converted to this new design, which had been called in development the TX-36-X2.

(b)(3)

The program included environmental, drop and neutron-generator compatibility tests, and demonstrated that the weapon was more than adequate to withstand the stockpile-to-target sequence. Both land and water targets had been included in the drop-test program, with release altitudes between 20,000 and 50,000 feet.[89]

On January 9, 1959, Albuquerque Operations Office canceled the Mk 36 program. The Mk 36 Mod 1 Bombs scheduled for updating would remain in current status until retirement in mid-1959.[90] This retirement program was later deferred to mid-1961.

RESTRICTED DATA

UNCLASSIFIED

Glossary of Terms

Air Force Special Weapons Center -- That element of the Air Force Systems Command having to do with compatibility testing of nuclear devices with aircraft. Located at Kirtland Air Force Base, Albuquerque, New Mexico.

Albuquerque Operations Office -- The local office of the Atomic Energy Commission (AEC) concerned with the operations of Sandia Corporation.

Armed Forces Special Weapons Project -- An interdepartmental agency formed to handle military functions related to atomic weapons.

Arming -- The act of arming a weapon; that is, preparing it for firing.

(b)(1), (b)(3)

Division of Military Application -- An AEC office that functions as liaison between the Military and weapons designers and producers.

RESTRICTED DATA

UNCLASSIFIED

Thermal Battery -- A battery whose electrolyte is in a solid state while inactive. To activate, heat is applied to this electrolyte, melting it and putting the battery into active output condition.

Thermonuclear -- Two-stage reaction, with a fission device exploding and starting a fusion reaction in light elements.

Tritium -- The hydrogen isotope of mass number 3.

Two-Stage -- Combination of fission and fusion action in a weapon.

TX Committee -- A joint committee of Los Alamos and Sandia members, established to guide the development of implosion-type weapons.

TX-Theta Committee -- A committee established to guide the development of thermonuclear weapons.

University of California Radiation Laboratory -- A laboratory established under the guidance of the University of California to work on thermonuclear designs, and located at Livermore, California.

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent uranium-238; the rest is uranium-235.

X-Unit -- ~~A high-voltage transformer~~. A device used to provide high voltage to the weapon detonator.

Mk 21 Exterior View

Timetable of Mk 21/26 Events

1/15/54	TX-Theta Committee meets. (b)(1), (b)(3) TX-21 nomenclature assigned.
	(b)(1), (b)(3)
3/26/54	Weight reduction of TX-21 proposed.
4/15/54	Military characteristics released. (b)(1), (b)(3)
6/4/54	TX-Theta Committee proposes expedited schedule.
6/7/54	Santa Fe Operations Office issues go-ahead on TX-21 design.
7/1/54	Military Liaison Committee approves expedited schedule for TX-21.
7/23/54	Results of wind-tunnel tests reported.
9/1/54	Contact fuze proposed. (b)(1), (b)(3)
9/29/54	Proposed ordnance characteristics of TX-21 reviewed.
12/15/54	Air Force Special Weapons Center requests weight reduction.
1/6/55	(b)(1), (b)(3)
5/9/55	Aerodynamics report on TX-21 ballistic shape issued.
6/1/55	Design of Mk 21/26 reviewed by Special Weapons Development Board.
7/15/55	(b)(1), (b)(3) Parachute provided for retarded deliveries.
12/55	Mk 21 Mod 0 Bombs stockpiled.
6/27/56	Mk 21 Mod 1 with contact fuze design-released. TX-26 design subsequently deleted from program.
6/57	Stockpiled Mk 21 Bombs converted to Mk 36Y1 Mod 1.
11/57	Conversion program completed.

Sandia meanwhile had started scale studies of the TX-21 shape and, by early March 1954, had determined that it would require at least one spoiler band on the nose and another on the afterbody to produce adequate free-fall stability. It was thought that a flat area on the nose might eliminate the need for a nose band, and appropriate tests were scheduled. It was estimated that external dimensions could be definitely fixed by mid-1954; fuzing, firing and ballistic drop tests held in early 1955; design release effected in mid-1955; and early Mark production by January 1956.[5]

The weight of the bomb was discussed in the March 26, 1954 meeting of the TX-Theta Committee. (b)(3) This would allow the weapon to be delivered by the B-58 or Hustler bomber, then being designed. Los Alamos stated that any weight-reduction study would delay the overall program, and noted that bombers could refuel in the air after takeoff. There would thus be little difference in bomber range due to weapon weight.

After discussion, the Committee decided that an attempt would be made to trim the weight to 15,000 pounds. Sandia would test wind-tunnel models representing diameters between 48 and 54.5 inches, and would study the component space problems created by such diameters. It was requested that this investigation delay the program not more than one month.[6]

The military characteristics for a two-stage weapon in the 23,000-pound maximum weight class were released April 15, 1954.

(b)(1), (b)(3)

It was stated that more than one ballistic shape might be required for these various applications, but that the number of such shapes should be held to a minimum.

(b)(1), (b)(3)

The two weapons would have a near-contact burst as the primary option, achieved by a network of proximity fuzes, and these units would provide backup for the secondary air-burst option. The fuzing and firing systems in both options would be armed by a barometric switch. A true contact fuze for thermonuclear applications was being developed, but this design would require extensive testing.

Work was progressing on improved types of power sources, which would meet military requirements of minimum preparation time and long storage life; but nickel-cadmium batteries would be used in the early stockpiled weapons. A retarded trajectory was desired, due to the large yield of the weapon, and would be provided by a 24-foot-diameter parachute, reefed to provide a down-time of 75 seconds, as compared to an unreefed time-of-fall of 108 seconds. Use of this parachute would be controlled by equipment installed in the aircraft.

It was noted that the diameter of the bomb over the spoiler bands was 58.47 inches, the overall length was 148.37 inches, and the weight was 17,600 pounds.[20] The outer case was an aluminum-alloy shell which formed the main structural member of the bomb.

(b)(1), (b)(3)

The afterbody was a cylindrical extension of the warhead case, having the same diameter and being attached to it by an external bolting flange which also served as an aerodynamic spoiler band. Access doors were provided for battery installation, safety switch, and interconnecting box. All fuzing and firing components, with the exception of X-unit and pullout switch, were mounted on a plate readily accessible through the tail of the bomb after the parachute container was removed.

The bomb had four fins, with a 6- to 14-degree double-wedge shape, a 39-1/2-inch chord length, and an 80.9-inch span. The forward half of each fin was of sheet metal and the remainder of polyester-glass laminate. A proximity-fuze antenna was installed in the plastic portion of each fin.

Deployment of the 24-foot-diameter parachute could be selected at any time prior to weapon release. Fuzing and firing system components were the same as the TX-15 Bomb, with the exception of X-unit and cabling. A remote-setting baroswitch provided a detonation signal for air bursts, and a network of four proximity fuzes provided the signal for near-contact bursts, as well as cleanup for air-burst failures. Safe separation was provided by a baroswitch that was set prior to takeoff of the strike bomber.[21]

The Division of Military Application notified the Military Liaison Committee October 25, 1954, that the TX-21 would be design-released in March 1955, with stockpile entry in August 1955. To meet this schedule, it had been necessary to assign the highest priority to the development.

(b)(1), (b)(3)

(b)(1), (b)(3)

It was hoped that a contact fuze could be introduced into the Mk 21/26 stockpile by mid-1956.[22]

Some concern was felt about the firing-switch contact buttons. These buttons were made of molybdenum and, during humidity testing, developed an insulating layer of oxide. The contacts were plated with palladium, which resisted oxide formation, but the necessary plating thickness and uniformity could not be secured, and firing tests showed that the film of molybdenum oxide would not prevent proper switch operation. Consequently, the palladium plating requirements were deleted in late October 1954.[23]

The Air Force Special Weapons Center wrote to Sandia December 15, 1954, noting that the weapon weight would be acceptable, but that efforts should be made to reduce this to the desired 15,000 pounds. A question was raised whether proximity fuzes would satisfy the military requirements for near-surface bursts, and it was recommended that a true contact fuze be developed. In this connection, it was suggested that an extendible probe-type impact device be studied.

(b)(3)

Sandia had made a study of contact fuzing and reported to the January 12, 1955 meeting of the Special Weapons Development Board. Sled and drop tests had indicated that the crystals developed for the Mk 17 Bomb would also be satisfactory for the TX-21. Also being considered was a double-shell contact device, having a false nose which contained two conductors separated by a plastic insulating layer.[25]

Report SC3608(TR), Design and Description Report at Design Release of the Mk 21/26 Mod 0 Bomb, was reviewed in the June 1, 1955 meeting of the Special Weapons Development Board. The bomb was 58.48 inches in diameter over the spoiler bands, and 149.6 inches long. (b)(1), (b)(3)

Either free-fall or parachute-retarded deliveries were possible. A 16-foot parachute furnished a 75-second time-of-fall.

The drop-test program was still under way, with nine ballistic and three fuzing and firing drops completed. Ballistic performance was satisfactory, but some parachute oscillations had been noted, and this problem was being solved as the test program progressed.

(b)(1), (b)(3)

This required an increased aircraft escape time of 100 seconds, and Wright Air Development Center was requested to develop a 24-foot-diameter parachute. It was felt that a two-stage deployment system would have to be used to mitigate the opening shock of the larger canopy.[33]

Report SC3694(TR), Engineering Evaluation of the Mk 21 Mod 0 Weapon, was presented to the December 14, 1955 meeting of the Special Weapons Development Board. Environmental resistance had been determined by component testing to performance standards, as well as overall weapon testing in arctic, tropic and desert environments. Models had been subjected to thermal tests; tests simulating loads involved in flights of B-47 and P6M aircraft; railroad humping tests; and rain, sand, dust, salt spray and sunshine tests. A total of 42 units had been drop-tested, including ballistic free-fall units, ballistic parachute units with proximity fuzes, ballistic parachute units with contact fuzes, and fuzing and firing units.

(b)(1), (b)(3)

after the safe-separation interval (determined by the setting of the arm baroswitch), the X-unit started to charge and the proximity fuzes were armed. A 3-second delay was provided by a timing device to prevent firing before the X-unit attained its normal charge.

As the bomb reached the desired burst altitude, the firing baroswitch closed, actuating the firing switch in the X-unit, discharging the capacitor bank into the detonator bridge wires, and initiating the explosive and nuclear sequence. If the system malfunctioned, the proximity fuze detonated the bomb. The parachute was deployed after release from the aircraft, if the retarded option had been selected. If a near-surface burst was selected, the barometric fuze was set at -3000 feet and the proximity fuze detonated the weapon.

(b)(1), (b)(3)

The Mk 21 Mod 0 first appeared in stockpile December 1955, and final deliveries were made in July 1956.

(b)(1), (b)(3)

The TX-26 was never authorized for production.[38]

Meanwhile, work had been proceeding on the design of a true contact fuze.[39] Report SC3606(TR), Proposed Electrical Characteristics for the Fuzing and Warhead Systems for the TX-15-X1 and the TX-21/26-X1 Weapons, was presented to the April 27, 1955 meeting of the Special Weapons Development Board.

(b)(1), (b)(3)

(b)(1), (b)(3) Drops had not as yet been made with parachute retardation, since the parachute design had not stabilized to the point where the test would be meaningful.

(b)(1), (b)(3) Due to the marginality of the data obtained, it was felt necessary to refine the test devices for an exact simulation of the weapon.[41]

The program was further discussed in the February 29, 1956 meeting of the Special Weapons Development Board.

(b)(1), (b)(3)

Sandia presented Report SC3826(TR), Design and Description at Design Release of the Mk 21/26 Mod 1 Bomb, to the June 27, 1956 meeting of the Special Weapons development Board. It was noted that the nose of this design was the same as the Mod 0 except for the impact crystal installation, and that the parachute and afterbody were identical. New contact crystals and a baroswitch were provided. The new crystals gave more consistent performance and were installed in a less critical area. The baroswitch contained four elements, ganged to make up the firing baroswitch, and these could be manually set to the desired burst altitude. Other elements in the baroswitch acted as the arming device, and these were automatically set 4000 feet higher than the firing altitude.[43] The Mk 21 Mod 1 was never produced.

Timetable of TX-22 Events

9/18/53 (b)(1), (b)(3)

10/29/53 Santa Fe Operations Office authorizes Sandia to assist in the above design.

2/2/54

(b)(1), (b)(3)

4/30/54

TX-22

(b)(1), (b)(3)

Sandia was requested to develop preliminary ballistic configurations, as well as requisite parachute ~~and~~ and fuzing and firing components.[48]

(b)(1), (b)(3)

The Santa Fe Operations Office requested Sandia, October 29, 1953, to assist the Radiation Laboratory in work on the aerodynamic case. Sandia would also design the fuzing and firing system, and conduct flight tests for both ballistics and systems prove-out.[49]

A review of a prospective drop-test program was held November 19, 1953. The devices would be released from a B-36 bomber flying at an altitude of 40,000 feet.

(b)(1), (b)(3)

The question of parachute retardation was raised, and was subsequently referred to the Air Force Special Weapons Center.

(b)(1), (b)(3)

(b)(1), (b)(3)

However, these calculations assumed that no clouds were present in the burst area to reflect thermal radiation onto the bomber and crew.

(b)(1), (b)(3)

By mid-January 1954, work on the ballistic design had progressed to the point where it was obvious that a modified TX-13 case could not be used, and the Division of Military Application authorized development of a special design.[52, 53]

(b)(1), (b)(3)

Plans were now made for test-firing.

(b)(3)

Sandia wrote to the Air Force Special Weapons Center February 15, 1954, requesting the support of the Center and the 4925th Special Weapons Group in the TX-22 ballistics test program, which would start in August 1954. Refinement of weapon parameters noted that the cylindrical case would have a diameter of 51 inches, fin box dimension of 56 inches, length (including parachute) of 145 inches, and maximum weight of 18,000 pounds. Several units would be dropped free-fall, but the majority would be parachute-retarded. The fuzing and firing signals would be provided by baroswitches, with a proximity fuze as backup.

The carrier would be the B-47 aircraft, using a reinforced TX-15 sling and rack. Both B-36 and B-52 aircraft would later be used. Plans were made for 30 tests, with early drops for ballistic and parachute study, and fuzing and firing tests starting in late 1954.[55]

(b)(1), (b)(3)

Timetable of Mk 36 Events

11/22/55	(b)(1), (b)(3)
1/3/56	TX-36-X1 design released.
4/56	Mk 36 Mod 0 enters stockpile.
5/56	Mk 21/36 Mod 1 Bomb design released.
7/13/56	TX-36-X2 program authorized for development.
9/24/56	(b)(1), (b)(3)
10/24/56	Proposed ordnance characteristics of TX-36-X2 Bomb reviewed by Special Weapons Development Board.
10/56	Mk 21/36 Mod 1 Bomb enters stockpile.
11/15/56	(b)(1), (b)(3)
4/12/57	TX-36-X2 program suspended.
4/22/57	(b)(1), (b)(3)
7/11/57	Resumption of work on TX-36-X2 authorized.
7/57	(b)(1), (b)(3)
4/23/58	TX-36-X2 design released.
1/9/59	Albuquerque Operations Office cancels Mk 36 programs.

Mk 36

(b)(1), (b)(3)

The TX-21-X1 program was subsequently canceled, but the TX-36-X1 was design-released January 3, 1956, and became, in production, the Mk 36 Mod 0.[63, 64] The weapon entered stockpile in April 1956 with a proximity fuze and internal initiator.[38]

Meanwhile, other improvements in the Mk 21 design had been suggested, principally in the fuzing and firing system. This work had begun in early 1955 in connection with the Mk 15 and Mk 39 programs, and the proposed design would provide options of either air burst or true contact firing. The weapon would be armed and fired by barometric switches, and the contact crystals would act either as primary fuze or as backup to the air-burst system. Thermal batteries would replace the nickel-cadmium units and would supply both low-voltage power for the fuzing system and high-voltage power for charging the X-unit.

Report SC3826(TR), Design and Description Report at Design Release of the Mk 21/36 Mod 1 Bomb, was released May 1956. This noted that the yield, weight, and

physical configuration of the Mod 1 was essentially identical with the Mod 0, with the exception of the fuzing and firing system. The Mod 1 would be employed in a high-altitude level release, using either a free-fall or retarded trajectory.

(b)(1), (b)(3)

Baroswitch settings were made on the ground prior to aircraft takeoff by a single dial setting. This setting was computed by comparing the intended height of burst with the target elevation above sea level and including a 300-foot offset correction. Prior to bomb release from the strike aircraft, the selector switch was placed at either air- or ground-burst position, the nuclear capsule inserted, the safing switch placed in the armed position, and the option switch placed at either the open or closed position, depending on whether ground or air burst had been selected.

The release of the bomb from the aircraft closed a pullout switch in the high-voltage-battery firing circuits, and operated magneto generators which furnished electrical pulses to ignite the low-voltage batteries. Power from these batteries was applied to the open contacts of the arm baroswitch. When the arm baroswitch closed, at the appropriate point in the weapon trajectory, low-voltage power was applied through the closed pullout switch and safing switch to the activating circuits of the high-voltage batteries, placing these latter devices in operating condition. The 2500 volts provided by these batteries charged the X-unit and supplied plate voltage to the trigger circuit.

If air-burst option had been selected, closure of the firing baroswitch applied a signal from the low-voltage batteries to the trigger circuit, thus detonating the bomb. If ground-burst option had been selected, the option switch held the firing circuit open, allowing the weapon to fall to the ground, where the contact fuze supplied the detonation signal.[65]

The Mk 21 Mod 1 Bomb was never produced, but the Mk 36 Mod 1 design entered stockpile in October 1956.

(b)(1), (b)(3)

(b)(1), (b)(3)

/The TX-36-X2 would be design-released in June 1957 with early production scheduled for July 1958 and operational availability in the fall of 1958.[69]

(b)(1), (b)(3)

On July 11, 1957, the Albuquerque Operations Office sent a teletype to Sandia, authorizing resumption of development and production activities on the TX-36-X2 program and requesting revised schedule dates, hopefully including an early production Mod-kit date of September 1958. Sandia replied, August 9, 1957, that a product definition was being prepared, and that it was hoped that the design could be released by October 1957.[81]

Report SC4113(TR), Design and Description Report at Design Release of the Mk 36Y2 Mod 1 Bomb. was issued July 1957.

(b)(3)

The TX-36-X2 became the Mk 36 Mod 2 and retrofit to this modification was planned for about half the Mk 36 Mod 1 Bombs in the stockpile. The Mod 2 incorporated a trajectory baroswitch-controlled, high-voltage safing switch to prevent inadvertent charging of the X-unit. The system also included a manually set baroswitch, desirable from reliability and operational standpoints.[83]

Sandia suggested to the Albuquerque Operations Office January 22, 1958, that Mk 36 Mod 1 Bombs which were not to be retrofitted to Mod 2 status be fitted with the safing switch.

(b)(1), (b)(3)

It was also felt that consideration should be given to the replacement of the remotely set baroswitch with a manually controlled design, since the first switch required aircraft equipment for baroswitch setting.

(b)(1), (b)(3)

It was recommended that the above changes to the Mod 1 and Mod 2 Bombs be authorized for production and that the designs be identified as the TX-36-Y1-X3 and TX-36-Y2-X3 programs. Since present planning envisaged retirement of the Mk 36 Mod 1 stockpile by mid-1960, this proposed modification would match the retirement program.[84]

(b)(3)

Report SC4222(TR), Final Evaluation of the Mk 36Y2 Mod 1 Bomb, was presented to the December 17, 1958, meeting of the Special Weapons Development Board.

(b)(1), (b)(3)

(b)(1), (b)(3)

Dynamic drop tests to ultimate loads, railroad humping tests, extreme temperature tests, and a simulated 6-month tropic storage test had been conducted, and these demonstrated the ability of the weapon to withstand these environments.[89]

At the above Board meeting, Report SC4188(TR), Final Evaluation of the Mk 36Y1 Mod 2 Bomb, was also presented.

(b)(1), (b)(3)

About half the existing stockpile of Mk 36Y1 Mod 1 Bombs would be converted to this new design, which had been called in development the TX-36-X2.

(b)(3)

The program included environmental, drop and neutron-generator compatibility tests, and demonstrated that the weapon was more than adequate to withstand the stockpile-to-target sequence. Both land and water targets had been included in the drop-test program, with release altitudes between 20,000 and 50,000 feet.[89]

On January 9, 1959, Albuquerque Operations Office canceled the Mk 36 program. The Mk 36 Mod 1 Bombs scheduled for updating would remain in current status until retirement in mid-1959.[90] This retirement program was later deferred to mid-1961.

Drogue Parachute -- A parachute that slows the rate of fall of a bomb.

(b)(1), (b)(3)

Field Command -- The local office of the Armed Forces Special Weapons Project, located on Sandia Base, Albuquerque, New Mexico.

Firing System -- The electrical system of the weapon that produces and applies a high-voltage current to the detonators.

Fuzing System -- The system that ~~signals the start of high voltage charging of the firing system.~~ arms the weapon at the appropriate time and provides a firing signal to the firing system at the selected burst height.

g -- Force equal to one unit gravity.

Gas Boosting -- The technique of increasing the yield of a nuclear device by introducing deuterium-tritium gas into the implosion process to increase the fission activity.

High-Explosive Sphere -- The ball of high explosive that surrounds the nuclear ~~primary assembly and~~ first and capsule and is designed to produces the implosion effect when detonated.

(b)(1), (b)(3)

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Knot -- A naval unit of speed, equivalent to 1 nautical mile or 6076 feet per hour.

(b)(1), (b)(3)

(b)(1), (b)(3)

Mach -- A measure of speed. Mach 1.0 is the speed of sound, or 738 miles per hour at sea level.

Megaton -- A measure of yield of a large weapon. One megaton is the equivalent of 1,000,000 tons of high explosive.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

Mod Kit -- A kit of parts which can be applied to a weapon to change the Mod number of the weapon.

Neutron -- An uncharged particle of slightly greater mass than the proton.

One-Point Safe Weapon -- A weapon that will not produce a nuclear yield when detonated at one point on the surface of the high explosive.

Operation Castle -- See Castle.

Operation Redwing -- See Redwing.

Oralloy -- A code term for enriched uranium. The two initial letters stand for Oak Ridge (*where Orally was first made in quantity*), *added to* alloy *from Tube* Alloys, Ltd. (the name of the British wartime atomic-energy project).

(b)(3)

Thermal Battery -- A battery whose electrolyte is in a solid state while inactive. To activate, heat is applied to this electrolyte, melting it and putting the battery into active output condition.

Thermonuclear -- Two-stage reaction, with a fission device exploding and starting a fusion reaction in light elements.

Tritium -- The hydrogen isotope of mass number 3.

Two-Stage -- Combination of fission and fusion action in a weapon.

TX Committee -- A joint committee of Los Alamos and Sandia members, established to guide the development of implosion-type weapons.

TX-Theta Committee -- A committee established to guide the development of thermonuclear weapons.

University of California Radiation Laboratory -- A laboratory established under the guidance of the University of California to work on thermonuclear designs, and located at Livermore, California.

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent uranium-238; the rest is uranium-235.

X-Unit -- ~~A high-voltage transformer~~. A device used to provide high voltage to the weapon detonator.

Mk 21 Exterior View

Timetable of Mk 21/26 Events

1/15/54	TX-Theta Committee meets. (b)(1), (b)(3) TX-21 nomenclature assigned.
3/26/54	Weight reduction of TX-21 proposed.
4/15/54	Military characteristics released. (b)(1), (b)(3)
6/4/54	TX-Theta Committee proposes expedited schedule.
6/7/54	Santa Fe Operations Office issues go-ahead on TX-21 design.
7/1/54	Military Liaison Committee approves expedited schedule for TX-21.
7/23/54	Results of wind-tunnel tests reported.
9/1/54	Contact fuze proposed. (b)(1), (b)(3)
9/29/54	Proposed ordnance characteristics of TX-21 reviewed.
12/15/54	Air Force Special Weapons Center requests weight reduction.
1/6/55	(b)(1), (b)(3)
5/9/55	Aerodynamics report on TX-21 ballistic shape issued.
6/1/55	Design of Mk 21/26 reviewed by Special Weapons Development Board.
7/15/55	(b)(1), (b)(3) Parachute provided for retarded deliveries.
12/55	Mk 21 Mod 0 Bombs stockpiled.
6/27/56	Mk 21 Mod 1 with contact fuze design-released. TX-26 design subsequently deleted from program.
6/57	Stockpiled Mk 21 Bombs converted to Mk 36Y1 Mod 1.
11/57	Conversion program completed.

The two weapons would have a near-contact burst as the primary option, achieved by a network of proximity fuzes, and these units would provide backup for the secondary air-burst option. The fuzing and firing systems in both options would be armed by a barometric switch. A true contact fuze for thermonuclear applications was being developed, but this design would require extensive testing.

Work was progressing on improved types of power sources, which would meet military requirements of minimum preparation time and long storage life; but nickel-cadmium batteries would be used in the early stockpiled weapons. A retarded trajectory was desired, due to the large yield of the weapon, and would be provided by a 24-foot-diameter parachute, reefed to provide a down-time of 75 seconds, as compared to an unreefed time-of-fall of 108 seconds. Use of this parachute would be controlled by equipment installed in the aircraft.

It was noted that the diameter of the bomb over the spoiler bands was 58.47 inches, the overall length was 148.37 inches, and the weight was 17,600 pounds.[20] The outer case was an aluminum-alloy shell which formed the main structural member of the bomb.

(b)(1), (b)(3)

The afterbody was a cylindrical extension of the warhead case, having the same diameter and being attached to it by an external bolting flange which also served as an aerodynamic spoiler band. Access doors were provided for battery installation, safety switch, and interconnecting box. All fuzing and firing components, with the exception of X-unit and pullout switch, were mounted on a plate readily accessible through the tail of the bomb after the parachute container was removed.

The bomb had four fins, with a 6- to 14-degree double-wedge shape, a 39-1/2-inch chord length, and an 80.9-inch span. The forward half of each fin was of sheet metal and the remainder of polyester-glass laminate. A proximity-fuze antenna was installed in the plastic portion of each fin.

Deployment of the 24-foot-diameter parachute could be selected at any time prior to weapon release. Fuzing and firing system components were the same as the TX-15 Bomb, with the exception of X-unit and cabling. A remote-setting baroswitch provided a detonation signal for air bursts, and a network of four proximity fuzes provided the signal for near-contact bursts, as well as cleanup for air-burst failures. Safe separation was provided by a baroswitch that was set prior to takeoff of the strike bomber.[21]

The Division of Military Application notified the Military Liaison Committee October 25, 1954, that the TX-21 would be design-released in March 1955, with stockpile entry in August 1955. To meet this schedule, it had been necessary to assign the highest priority to the development.

(b)(1), (b)(3)

after the safe-separation interval (determined by the setting of the arm baroswitch), the X-unit started to charge and the proximity fuzes were armed. A 3-second delay was provided by a timing device to prevent firing before the X-unit attained its normal charge.

As the bomb reached the desired burst altitude, the firing baroswitch closed, actuating the firing switch in the X-unit, discharging the capacitor bank into the detonator bridge wires, and initiating the explosive and nuclear sequence. If the system malfunctioned, the proximity fuze detonated the bomb. The parachute was deployed after release from the aircraft, if the retarded option had been selected. If a near-surface burst was selected, the barometric fuze was set at -3000 feet and the proximity fuze detonated the weapon.

(b)(1), (b)(3)

The Mk 21 Mod 0 first appeared in stockpile December 1955, and final deliveries were made in July 1956.

(b)(1), (b)(3)

The TX-26 was never authorized for production.[38]

Meanwhile, work had been proceeding on the design of a true contact fuze.[39] Report SC3606(TR), Proposed Electrical Characteristics for the Fuzing and Warhead Systems for the TX-15-X1 and the TX-21/26-X1 Weapons, was presented to the April 27, 1955 meeting of the Special Weapons Development Board.

(b)(1), (b)(3)

All Mk 21 Bombs were withdrawn from stockpile in the period June through November 1957, and were converted into Mk 36Y1 Mod 1's.[38]

Timetable of Mk 36 Events

11/22/55	(b)(1), (b)(3)
1/3/56	TX-36-X1 design released.
4/56	Mk 36 Mod 0 enters stockpile.
5/56	Mk 21/36 Mod 1 Bomb design released.
7/13/56	TX-36-X2 program authorized for development.
9/24/56	(b)(1), (b)(3)
10/24/56	Proposed ordnance characteristics of TX-36-X2 Bomb reviewed by Special Weapons Development Board.
10/56	Mk 21/36 Mod 1 Bomb enters stockpile.
11/15/56	(b)(1), (b)(3)
4/12/57	TX-36-X2 program suspended.
4/22/57	(b)(1), (b)(3)
7/11/57	Resumption of work on TX-36-X2 authorized.
7/57	(b)(1), (b)(3)
4/23/58	TX-36-X2 design released.
1/9/59	Albuquerque Operations Office cancels Mk 36 program.

Thermal Battery -- A battery whose electrolyte is in a solid state while inactive. To activate, heat is applied to this electrolyte, melting it and putting the battery into active output condition.

Thermonuclear -- Two-stage reaction, with a fission device exploding and starting a fusion reaction in light elements.

Tritium -- The hydrogen isotope of mass number 3.

Two-Stage -- Combination of fission and fusion action in a weapon.

TX Committee -- A joint committee of Los Alamos and Sandia members, established to guide the development of implosion-type weapons.

TX-Theta Committee -- A committee established to guide the development of thermonuclear weapons.

University of California Radiation Laboratory -- A laboratory established under the guidance of the University of California to work on thermonuclear designs, and located at Livermore, California.

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent uranium-238; the rest is uranium-235.

X-Unit -- ~~A high-voltage transformer~~. A device used to provide high voltage to the weapon detonator.

History of the Mk 48 Shell

The predecessor of the Mk 48 Shell was the Mk 33, an 8-inch-diameter, artillery-fired atomic projectile. While this latter shell was still being designed, the Under Secretary of the Army wrote to the United States Atomic Energy Commission, April 28, 1954, expressing interest in the possibility of developing an even smaller diameter projectile with a very low yield, and a broad study was subsequently authorized by the Secretary of Defense May 14, 1954.

The intent of this study was to investigate the possibility of using implosion techniques in an atomic artillery shell, rather than the gun method used in previous shell designs, but the state of the art was not sufficiently well advanced. Much work was, however, accomplished in the ensuing 12 months by the University of California Radiation Laboratory and resulted in a request from the Secretary of Defense to the Atomic Energy Commission, April 4, 1955, for a feasibility study of an 8-inch shell having advanced nuclear techniques. (b)(1), (b)(3)

4/4/55	Work by the University of California Radiation Laboratory results in request by the Secretary of Defense for a feasibility study of an 8-inch implosion shell.

(b)(1), (b)(3)

9/20/56	Assistant Secretary of Defense requests United States Atomic Energy Commission to concentrate on atomic artillery shells of 155mm (6.1 inches) diameter.
7/12/57	Assistant Secretary of Defense requests that 155mm atomic implosion projectile be developed.
5/14/58	Developmental guidelines between Atomic Energy Commission and Department of Defense for development of 155mm shell issued.

(b)(1), (b)(3)

8/4/59	Military characteristics approved by the Military Liaison Committee.
11/6/59	Sandia forwards development program definition to AEC.

(b)(1), (b)(3)

3/23/60	Military Liaison Committee suspends higher yield requirement.
1/63	Mk 48 Mod 0 Shell design released.
10/26/63	Early production of Mk 48 Mod 0 Shells.
5/64	Final development report approved and published.

Other components included a corona regulator tube, ceramic spark gap, and an inertial or setback switch. If the tube could not be designed to resist firing shock, other methods of regulation were available that could meet requirements of small size, rugged construction, and dependable operation. An extensive reliability study of the spark gap would have to be made. Due to experience gained on other designs, it was felt that the setback switch would impose no particular problems.[13]

The Army informed Sandia July 16, 1958 that, as the caliber of the implosion shell decreased, the magnitude of the associated engineering problems increased. It was therefore suggested that detailed consideration be limited to the design of a shell with a minimum diameter of 155mm. It was recommended that development engineering be authorized for a shell for the 155mm howitzer and the 175mm gun, but that general small-caliber research be continued.

(b)(1), (b)(3)

(b)(1), (b)(3)

(b)(3)

The higher yield, however, was desired and would be retained in the military characteristics.[23]

The Military Liaison Committee forwarded an amendment to the military characteristics May 2, 1960. This required that the XW-48 be compatible with M1A1 and T258 howitzers.[24] The Lawrence Radiation Laboratory and Sandia had previously informed Picatinny Arsenal that it was not possible, either through calculations or completed tests, to estimate with confidence the ability of the projectile to withstand the T258 environment, as Picatinny had indicated that this new application would subject the shell to angular accelerations 25 percent greater than previously anticipated. However, suitable tests would be conducted.[25]

These tests were subsequently made at the Army's Yuma, Arizona, test station. Linear accelerations of 12,000 g's were recorded, together with angular accelerations of 190,000 radians per second per second, the T258 howitzer environment. No premature firings were experienced, and no damage to shell components resulted. Thus, Sandia notified Albuquerque Operations Office January 15, 1961 that the T258 howitzer and XW-48 Shell were compatible.[26]

subsequently approved and published in May 1964. (b)(1), (b)(3)

It was integrated with a number of components supplied by the Department of the Army to form the XM454, an artillery-fired atomic projectile designed to be fired from 155mm howitzers equipped with either M1A1 or T258 tubes. The maximum range of the projectile was 14,000 meters, or 8.5 miles. The minimum fuze-setting range was 1650 meters, or about 1 mile, which provided safe distance from nuclear detonation. The projectile was 155mm (6.1 inches) in diameter, 34 inches (5.57 calibers) long, and weighed 120 pounds.

RESTRICTED DATA

History of the Mk 25 Warhead

As the weight of nuclear devices began to shrink and their yields to increase, it became apparent that many types of aircraft and missiles could be fitted with nuclear or thermonuclear warheads, making it at least theoretically possible for a potential enemy to saturate the defenses of the United States with a single massive attack. A system which destroyed a reasonable percentage of the attacking bombers would provide adequate defense against conventional bombs, but a relatively small number of well-placed atomic weapons could do much toward destroying an industrial complex.

There was no competent defense against such an attack; in fact, there was not even an adequate counter to the V-2 missile used by the Germans in World War II. Enemy air bases and launching sites could be destroyed, and the Strategic Air Command had assigned high priority to these targets. However, since the national policy was not to strike first, it was obvious that the country would have to be prepared to absorb the initial brunt of an all-out attack by an aggressor.[1] The Division of Military Application accordingly suggested, March 13, 1951, that some thought be given to providing a nuclear warhead to be used as a weapon of defense against mass aircraft raids.[2] Little immediate action was taken, however, since the existing state-of-the-art, both in warheads capable of high-altitude operation, and in missiles capable of achieving such altitudes with the requisite accuracy, was not sufficiently advanced.

As the capabilities of both warheads and missiles increased, the Joint Chiefs of Staff, February 27, 1952, requested their Joint Air Defense Board to study the situation. This study took place during much of 1952 and, October 29, 1952, the Military Liaison Committee notified the Division of Military Application that it was entirely possible that a

RESTRICTED DATA

SECRET

UNCLASSIFIED

military requirement for one or more specific weapons for air defense would be forthcoming in the near future. It was requested that the Atomic Energy Commission undertake preliminary investigation of the problems involved in developing air defense atomic warheads, with particular reference to the ability of such warheads to operate at high altitudes.[3]

The Joint Air Defense Board completed its study and released a report January 14, 1953. This report listed the various potential carriers for atomic devices, such as guns, rockets, missiles, interceptor and bomber aircraft, and recommended the use of ground-to-air missiles such as the TALOS, BOMARC and NIKE, which would carry low yield, highly economical, and efficient nuclear warheads.[1]

The report was discussed in the January 12, 1953, meeting of the Special Weapons Development Board. It was predicted that air defense warheads would have to be produced in large numbers, possibly tens of thousands, in order to provide an effective defense of any sizable portion of the country. They would thus have to be economical, both in nuclear and non-nuclear costs. These weapons would have to be operationally ready at all times to respond to a surprise attack, and they would have to be able to withstand exposure to climatic extremes ranging from the arctic to the tropics. The weapons should require only minor maintenance, since it would not be possible to provide a sufficiently large group of thoroughly trained technicians.

The Air Force BOMARC was being designed for an extended perimeter defense which would use a long-range detection system, also being developed. The range of this detection system was from 250 to 300 miles. The BOMARC range would be 125 miles, initially, with a later extension to 250 miles. The early altitude capability would be 60,000 feet, and this would be increased to 100,000 feet as enemy capabilities increased. Since BOMARC would not be operational until 1959 or 1960, a Navy missile, the TALOS-W, was planned for interim use, and would be available about 2 years before

as it was felt that these weapons had to be specialized in order to provide an immediate readiness capability, maximum economy in the use of fissionable material, and a high degree of reliability against premature detonation. Such direction was provided in a letter from Field Command to Sandia dated October 15, 1953, and eventually several air defense warhead designs were produced, the Mks 25, 30 and 31.[7]

(b)(1), (b)(3)

At the request of the TX-N Committee, Sandia studied the optimum size for warheads for air-to-air use.

(b)(1), (b)(3)

The Atomic Energy Commission wrote to the Military Liaison Committee May 7, 1954, accepting responsibility for the development of a warhead for the air-to-air rocket.

(b)(1), (b)(3)

Field Command released a set of approved military characteristics for a 15-inch warhead May 18, 1954. (b)(1), (b)(3) The warhead would be capable of remaining in a ready-to-fire condition for a period of at least 30 days. It would be able to withstand, without damage, single mission

flights of 2 hours and a total flight duration of 50 hours at altitudes up to 100,000 feet and subject to temperatures ranging from -90°F to +165°F. Resistance to accelerations of ±100 g's along the longitudinal axis, ±20 g's along any perpendicular axis, and angular accelerations of 400 radians/second/second would be required. The firing system would be able to operate to an altitude of 100,000 feet.[11]

At the request of the TX-N Committee,[12] the designation XW-25 was assigned to the warhead June 4, 1954.[13] The Division of Military Application noted that the Air Force would be responsible for the ballistic case, arming and fuzing system, power supply, propulsion system, and associated assembly, test and handling equipment. The Atomic Energy Commission would provide the implosion warhead, including nuclear capsule, pit, high-explosive system, detonators, cables, X-unit, firing switch, nuclear insertion gear, sphere case, and associated assembly, test and handling equipment.[14]

The missile was given the code name of DING DONG, and a Joint Study Group named, with representatives from the Air Force Special Weapons Center, Armed Forces Special Weapons Project, Los Alamos, and Sandia, and this group initially met August 9, 1954. The weapon would be optimized for the F-102 interceptor, with secondary applications to the F-86, F-89 and F-100 aircraft. The Air Force Special Weapons Center was assigned overall responsibility for the weapon system, with the assistance of Wright Air Development Center.

The outer diameter of DING DONG, exclusive of fins, would be about 16.5 inches, but excursions to 15 and 18 inches would be investigated to determine their influence on performance. The total length of the weapon would be compatible with the launching restrictions of the applicable bomb bays. The use of both fixed and folding fins would be considered. If a reversible actuating mechanism for fin extension and retraction was provided, it would be capable of repeated operation while the weapon was being externally carried at air speeds up to 250 knots. If an automatic,

one-time fin operating device was used, its probability of operational failure was not to be greater than 1 in 10,000. This mechanism would have to operate at speeds up to Mach 1.5 and at altitudes up to 35,000 feet.

There would be three sequential signals required to detonate the warhead; one to actuate the nuclear arming mechanism, another to initiate electrical arming, and a third to provide the firing signals. The fuze would include a safe-separation feature to prevent premature warhead detonation. A detonation timing element, capable of being preset before aircraft takeoff, would be designed. The rocket would have a 2500 feet per second (1700 miles per hour) velocity increase over its aircraft speed and a flight time of 15 seconds to target. The weapon would be used tactically at all altitudes up to 50,000 feet.[15]

(b)(1), (b)(3)

A study of kill versus yield was made by the Joint Study Group, and published November 30, 1954.

(b)(1), (b)(3)

With the larger weapons, the launching range had to be increased to provide enough escape time. This increase in range decreased the probability of target detection, and more than offset any increase in effectiveness.

(b)(1), (b)(3)

In respect to the warhead diameter, the cost per kill in terms of nuclear material was less in the largest diameter studied, which was 18 inches. However, larger diameters would require corresponding increases in the size and weight of the carrying rocket and would cause aircraft compatibility problems. The recommended diameter was 17.25 inches.

(b)(1), (b)(3)

The study indicated that it would be desirable to provide a missile velocity increase of 3000 feet per second during the rocket flight and, since missile contractors had indicated that this would be possible, it was recommended that the rocket and warhead be designed to this specification.

The design criteria required that the warhead be considerably different than previous designs. It must be able to withstand 100 g's, it must be light so as to attain high velocity, it must be capable of being carried at high altitudes for many hours and still operate, and it must be capable of withstanding the very high temperatures generated in high speed flight.[17]

The Joint Study Group was later dissolved and reconstituted as the Air-to-Air Rocket Joint Project Group, and held its first meeting under the new title January 31, 1955. The warhead weight, by the latest estimate, was about 230 pounds, and Douglas Aircraft Company, which was to provide the rocket, was requested to design to this figure. The Group recommended that the warhead thermal battery be made an integral part of the X-unit and sealed into this package. An arm/safe switch, capable of being monitored, and located in the X-unit charging circuit, would be operated either automatically or manually.[18]

The Assistant Secretary of Defense, March 17, 1955, authorized full development activities on Project DING DONG. The Armed Forces Special Weapons Project would have normal responsibilities, but the Air Force would possess overriding authority within the Department of Defense during the development period.[19]

UNCLASSIFIED
SECRET

RESTRICTED DATA

Sandia notified Santa Fe Operations Office March 18, 1955, that the Military had indicated an urgent desire to have the DING DONG weapon operational by 1957. Since this meant that an appreciable number of weapons would have to be available at that time, it was requested that an authorization for quantity production be released.[20] The Atomic Energy Commission replied that since no firm production directive for the XW-25 Warhead had been received, it was premature to authorize production.[21]

(b)(1), (b)(3)

RESTRICTED DATA
SECRET
UNCLASSIFIED

(b)(1), (b)(3)

The Military Liaison Committee wrote to the Atomic Energy Commission March 30, 1955, requesting that the small atomic warhead be developed in time to match a predicted rocket availability date of January 1, 1957. This required that the warhead be ready for operational suitability tests by July 1, 1956. It was noted that feasibility studies were being made of this warhead for use in other applications, such as a demolition munition, but these studies were not to interfere with the urgent need for the air-to-air capability.

The warhead would be rugged, reliable, and easily installed and tested; it would be safe to transport and handle; and easy to use in combat. It would provide maximum interchangeability of nonnuclear components between it and other atomic warheads, although this requirement was not to preclude development of a sealed design.

(b)(1), (b)(3)

The diameter of the warhead would be 17-1/4 inches, and the weight and length would be held to a minimum.

The warhead installed in a weapon would be capable of storage in the ready-to-operate condition for a period of at least 30 days, but extension of this time to 90 days was desired if it could be attained on a not-to-delay basis. The warhead would be operable at altitudes up to 75,000 feet, with 100,000 feet as an ultimate goal. It would withstand temperatures and accelerations specified in the military characteristics.

(b)(1), (b)(3)

Santa Fe Operations Office notified the Division of Military Application April 15, 1955, that Sandia was planning system flight tests of the XW-25 between November 1955 and August 1956, warhead design release in March 1956, and early Mark-quality units delivered to War Reserve by mid-1957. This schedule could be accelerated if flight test rockets could be provided at an earlier date.[24]

Some concern had been felt over incorporating thermal batteries in the warhead. It was felt that this prevented nuclear safing, allowed components essential for full-scale nuclear detonation to be continuously present, and permitted the squibs of the batteries to be initiated by fire or any external radio frequency device. A careful evaluation was made and a report issued April 28, 1955, which described several methods of safing. These included removal of the batteries from the warhead, a safety device in the battery circuit, a thermally-operated switch to open the circuit in the event of fire, late arming switches in the high-voltage circuits, or an arm/safe switch in the warhead or adaption kit.

The first two methods would not contribute to the safety of the overall weapon. The thermally-operated switch would protect against only one type of failure. Late arming switches would have to be low-energy devices, and would be heat-sensitive. The arm/safe switch was thus selected for use. If this was located in the adaption kit, a high-voltage line would have to be extended from the sealed warhead compartment to the adaption kit. However, if the switch was placed in the warhead, it would be protected by the warhead seal and could be placed on the high side of the X-unit where it could also be used to short out the battery or capacitor and improve the safety margin. This switch would be actuated automatically, to guard against any possible degradation in reliability due to pilot error.[25]

The Air Force issued a report on the arming and fuzing system for the air-to-air rocket April 28, 1955. Three systems had been analyzed, and it was concluded that one with an arming plug and a monitored switch in

the warhead would have the least probability of premature detonation during storage. It was also concluded that protection against premature detonation before safe separation would be adequate if a thermal switch was provided.[26]

(b)(1), (b)(3)

Since high volume warhead production was anticipated, it was planned to delay production until much of the developmental and operational testing had been completed, in order to prevent any extensive retrofit. Thus Mark- quality warheads would not become available in quantity until September 1957.[27]

The Military Liaison Committee replied, May 19, 1955, that rocket development had been committed to a capability date of January 1, 1957. Initial application would be to 25 modified F-89 aircraft (which had replaced the F-102 due to a delay in the latter airplane), and which were to be available by late 1956.

(b)(3)

The DING DONG rocket design now began to take final shape, and was described in a letter from Field Command May 24, 1955. This unguided rocket would have a range from 3 to 5 miles, with an average incremental velocity of 3000 feet per second over its launch speed. The rocket could operate at altitudes up to 60,000 feet, but would be limited by interceptor performance, safe-escape range, radar detection angles, and angle of attack.

The overall length of the rocket (including warhead assembly) would be 114 inches, its maximum outside diameter, exclusive of fins, 17.25 inches, and its gross weight 807 pounds. The diameter with fins retracted would

were used to prevent running wires through the sealed portion of the warhead.

The primary aircraft carrier would be the F-102, which would be operationally available in late 1957. Since the intercept problem was complex, the pilot used an automatic fire-control system to launch the missile. This control system detected the target, provided course steering information to the aircraft pilot, and launched the weapon in accordance with a predetermined fuze setting.

(b)(3)

The nuclear system was hermetically sealed, thus eliminating corrosion problems.

The only handling equipment required for the warhead was a shipping container. Two testers would be provided; one to check the integrity of the warhead seal, and the other to test continuity in the thermal battery initiation circuit and monitor the position of the arm/safe battery switch. Since use of the weapon might be required at short notice, no preflight testing would be necessary. Periodic checks would, however, be made, ranging from a 30-day pressure seal check to an 18-month teardown to check the effects of aging on interior components.

Design release of the warhead was scheduled for July 1956, and a number of production units would be delivered by June 1957. The report was accepted by the Board and forwarded to the Division of Military Application.[32]

(b)(1), (b)(3)

sea level to 60,000 feet, with flight times (depending on altitude) of 5-1/2 to 12 seconds, and which were determined by the requirements for safe separation from the delivery aircraft. The GENIE weighed 800 pounds, was 115 inches long, and 17.5 inches in diameter.[37]

The Mk 25 Mod 0 Warhead had been design-released in July 1956, and stockpile entry effected in June 1957. The emergency capability units were completed on schedule.

(b)(1), (b)(3)

The warhead was sealed and pressurized to 15 pounds per square inch on assembly, to prevent arc-over of high voltages at high altitudes. Capability was established with the F-89 aircraft, with later application to the F-101 and F-106 as these became available.

Operation of the weapon was as follows: A ground-control center located an approaching enemy aircraft and directed the interceptor to it. The target was located on the interceptor's fire-control system, which provided attack information to the pilot. After the pilot switched to the special weapons option and the radar locked-on to the target, the fire-control system operated the arm/safe switch to the arm position. Subsequently, a capacitor used to fire the low-voltage thermal batteries in the fuze was charged and a timing signal issued.

The weapon was launched automatically by the fire-control system when the interceptor entered the correct position at the proper range, which was dictated primarily by radiation safety considerations. At launch, an acceleration switch opened and inertial switches closed and latched to fire low-voltage thermal batteries. The timer then started to operate. At burnout, about 2 seconds after launch, the acceleration switch closed, firing the warhead high-voltage thermal batteries, and charging the warhead capacitors. When the timer completed its rundown, the weapon

detonated. If the target was lost before launch, the arm/safe switch automatically returned to the safe position, and it could be subsequently rearmed or resafed as many times as necessary.

The successful completion of the program was greeted with enthusiasm by the Air Force, and Sandia was complimented on its part of the work.[38] The W25-0 was hailed as the first of a group of weapons that would require little inspection and would be called "wooden bombs," so termed because it was hoped their maintenance would be only that of a block of pine.

(b)(1), (b)(3)

Report SC4190(TR), Engineering Evaluation of the Mk 25 Mod 0 Warhead, was issued August 1958. The system environmental and initial flight test program had been successfully completed. Flight tests had proven compatibility of the warhead with the MB-1 or GENIE rocket, and resulted in certification of the F-89 aircraft as a carrier. Flight tests were continuing to prove compatibility of the weapon system with F-101 and F-106 aircraft.

A series of seven airdrop and five sled tests had shown that a charged X-unit would not discharge upon impact unless a firing signal had been received by the fuze, but that an armed fuze would probably fire. Thus, the probability of a nuclear detonation was high if a GENIE struck the ground with an armed fuze and X-unit. However, the probability of an air dud in such cases was low, since the primary cause of an air dud was an arming failure.[39]

The Division of Military Application authorized the installation of environmental sensing devices in the Mk 25 Warhead, and this information was furnished to Sandia by the Albuquerque Operations Office January 30, 1961.[40] Sandia subsequently designed the Mk 25 Mod 1 Warhead which was released October 1961 and entered stockpile March 1962. This change provided an inertial switch which was installed in the high-voltage battery activation circuit of the X-unit and prevented inadvertent operation of the warhead firing set until the warhead had experienced a launch acceleration.[41]

Atomic Demolition Munition

The Joint Chiefs of Staff recommended to the Secretary of Defense, October 28, 1953, that a lightweight atomic demolition munition be developed. On November 3, 1953, the Assistant Secretary of Defense requested that the Armed Forces Special Weapons Project coordinate a statement of suitable military characteristics for such a warhead 15 inches in diameter, 30 inches in length, and weight not over 200 pounds.

(b)(1), (b)(3)

The weapon would have a readiness period of 30 days, and be capable of disassembly into 40-pound packages.[42]

(b)(1), (b)(3)

Little work was done on the project, however, and the application was canceled in February 1956 in favor of similar devices on the Mk 30 and Mk 31 programs.[44]

HONEST JOHN, JR.

The Assistant Secretary of Defense notified the Atomic Energy Commission September 28, 1954, that the Army had initiated studies of an HONEST JOHN, JR., or short-range HONEST JOHN, weapons system, and wished to include an atomic capability with the XW-25 Warhead. It was requested that the AEC help in the project, but not to interfere with the high-priority development of the air-to-air application of this warhead.[45]

The proposed military characteristics for an adaption kit for this system were released by the Division of Military Application April 27, 1955.[46] These called for a small, implosion-type atomic warhead with a diameter from 15 to 17 inches. The weapon would be a surface-to-surface rocket fired from two types of launchers; a self-propelled and a lightweight helicopter-transportable version.

(b)(3)

The fuzing system would provide a signal to the warhead after a preset time had elapsed and a preset velocity had been attained. Again, little work was accomplished, and on February 28, 1956, the Division of Military Application notified Santa Fe Operations Office that the Army had discontinued plans for the above application, in favor of a warhead with a higher yield and small diameter.[44]

Boosted XW-25 Warhead

The Division of Military Application, July 13, 1956, noted that the Department of Defense had informally expressed concern about the lack of a boosted XW-25 Warhead.[47] Albuquerque Operations Office replied, in a teletype of July 25, 1956, that no formal interest in such a warhead had ever been stated, nor had the Laboratories been requested to undertake this development. The need for such a warhead was questioned, and it was requested that information be supplied as to whether this was due to a desire for nuclear economy, higher yield, or concern about plutonium contamination.[48]

The Division of Military Application responded, July 30, 1956, noting that the military request resulted from a study prepared at the request of the Joint Chiefs of Staff.

(b)(1), (b)(3)

This study was released August 14, 1956. It was noted that the GENIE rocket warhead compartment was not large enough to accommodate boosting equipment and that the development of a suitable system would result in an entirely new weapon design.[50]

(b)(1), (b)(3)

The Division of Military Application wrote to Los Alamos September 14, 1956, noting that a possible plutonium hazard would be created by the XW-25 when making peacetime intercepts of unidentified aircraft. Additionally, the Air Force had requested that a study be made of the feasibility of producing warheads containing only uranium-235, to reduce the hazards to civilian populations and air bases from contamination caused by one-point detonations or fire.

(b)(1), (b)(3)

A Joint Feasibility Group was convened, which reported November 9, 1956. This Group had examined several different types of nuclear designs, and noted that an implosion warhead containing only uranium-235 would ease the contamination problem, but that complete elimination would be possible only through use of a gun-type design. Radiological contamination was currently of much interest, and attempts were being made to minimize the hazards associated with the transportation, storage and use of atomic weapons.[53]

Subsequently, May 27, 1957, the Assistant Secretary of Defense directed the Atomic Energy Commission to cooperate with the Armed Forces Special Weapons Project and the Services in a feasibility study of an atomic warhead that would minimize the plutonium hazard of defense rockets. without unduly increasing the nuclear material costs.[54]

(b)(1), (b)(3)

(b)(1), (b)(3)

Safe-Separation Time -- A time interval provided by a timer to allow safe escape of an aircraft delivering a weapon before the weapon detonates.

Safing -- Putting a weapon in condition such that it cannot fire.

Santa Fe Operations Office -- The local office of the Atomic Energy Commission (AEC) concerned with the Sandia operations.

Sealed Pit -- A weapon in which all the nuclear components (except the boosting gas, when used) are permanently installed in place. Designed to eliminate the need for inflight nuclear insertion mechanisms.

Services -- The Department of Defense.

Special Weapons Development Board -- A joint Sandia-Military board at Sandia Base to provide local guidance on weapons design.

Squib -- A device containing a small powder charge. When detonated, the resulting gas pressure closes a switch or performs a similar action. A light, quick-acting, one-shot device.

Strategic Air Command -- A part of the United States Air Force devoted to the attack of strategic targets, such as industrial plants.

Teapot -- A less-than-full-scale test series held at the Nevada Test Site. Series of 14 tests, starting February 18 and ending May 15, 1955.

Thermal Battery -- A battery whose electrolyte is in a solid state while inactive. To activate, heat is applied to this electrolyte, melting it and putting the battery into active output condition.

Thermonuclear -- Two-stage reaction, with a fission device exploding and starting a fusion reaction in light elements.

Tritium -- The hydrogen isotope of mass number 3.

Two-Stage -- Combination of fission and fusion action in a weapon.

TX-N Committee -- A joint committee of Los Alamos Scientific Laboratory and Sandia members, established to guide the development of implosion-type weapons.

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3 percent uranium-238; the rest is uranium-235.

Warhead -- A weapon carried to the target by missile.

Wooden Bomb -- A weapon designed to have an infinite shelf life and to require no special storage or surveillance. "As trouble-free as a block of pine."

X-Unit -- ~~A high-voltage transformer.~~ A device used to provide high voltage for the weapon detonators.

Timetable of Events

Mk 27 Weapon

Late 1953 Plans made to develop a small, two-stage weapon.

(b)(3)

8/5/54

(b)(1), (b)(3)

6/6/55

7/6/55 Division of Military Application assigns Mk 27 development to Radiation Laboratory and Sandia-Livermore.

8/9/55

(b)(1), (b)(3)

6/27/56 Special Weapons Development Board discusses proposed ordnance characteristics of the TX-27 weapon.

(b)(1), (b)(3)

8/21/57 Mk 27 Bomb design released.

10/21/59 Final evaluation report of Mk 27 Mod 0 Bomb presented to Special Weapons Development Board and accepted.

Mod 1

6/22/59 Division of Military Application proposes that manual arming capability of the fuzing system be deleted.

9/28/59 Sandia provides ready-safe switch for above purpose, creating the Mk 27 Mod 1.

Mod 2

10/21/60 Sandia proposes that a squib-actuated switch be replaced with a solenoid actuated design, to prevent activation of the squib switch by radio-frequency energy. This resulted in the Mk 27 Mod 2 design.

REGULUS Warhead Application

5/21/55 (b)(3)

8/12/55 Sandia submits proposed scope of work for adaption kit for XW-27/ REGULUS I.

1/25/56 Special Weapons Development Board discusses proposed ordnance characteristics of the XW-27 Warhead and its missile applications.

3/27/57 W27/REGULUS I design released.

4/23/58 Final engineering evaluation of the Mk 27 Mod 0 REGULUS I Warhead Application presented to and accepted by the Special Weapons Development Board.

RASCAL Warhead Application

Mid-1955 Missile considered for XW-27 application.

1-57 Application design release issued.

4/23/58 Final engineering evaluation of the Mk 27 Mod 0/GAM-63A (RASCAL) Warhead application presented to and accepted by the Special Weapons Development Board.

B-58/HUSTLER Application

Summer 1953 Feasibility study of XW-27/B-58 proposed.

1/18/56 Project authorized for design.

6/57 Project canceled.

TRITON Warhead Application

8/54 Feasibility study for XW-27/TRITON authorized.

12/9/55 Project canceled.

MATADOR Warhead Application

12/16/54

(b)(3)

11/56 XW-27/MATADOR project canceled in favor of XW-28/MATADOR.

SHAPE 96 Warhead Application

1/12/55 Air Force Special Weapons Center states that project appears feasible.

5/24/55 Santa Fe Operations Office authorizes full development.

3/56 Project canceled.

HISTORY OF THE MK 27 WEAPON

In late 1953, as the design of the TX-15 began to crystallize, it became evident that major weight and size reductions of thermonuclear devices were possible.

(b)(1), (b)(3)

The weapon would be carried by the Army REDSTONE missile; the Navy REGULUS I, REGULUS II, and TRITON; and the Air Force B-58 Pod, MATADOR, SNARK, RASCAL and NAVAHO. The bomb weight was not to exceed 3000 pounds. It was to be capable of either internal or external carriage on the Navy AJ, A2U, A3D, A4D, F3H, F7U, P6M and F2H; and the Air Force B-47, B-52, B-57, B-66, F-84, F-100, F-101 and F-105.

The bomb would be able to withstand, without damage or functional impairment, forces and accelerations caused by catapulted takeoffs, arrested landings, ejection, and normal flight maneuvers. A surface-burst contact fuze was desired, selectable in flight as a primary burst option, but a radar fuze producing a near-surface burst would be acceptable if a true contact fuze could not be achieved. An air-burst fuze would be capable of being set to the desired burst height after takeoff, and a contact or near-surface fuze would provide cleanup. The weapon would be capable of remaining in a ready-for-use condition for as long a period of time as possible, but not less than 30 days.[3]

(b)(1), (b)(3)

(b)(3)

It was hoped that the devices would be produced in late 1956, by which date suitable delivery aircraft would be available. It was felt, however, that if a maximum bomb weight of 3000 pounds was maintained, the warhead weight might be less than the specified 2800 pounds, and that it would have a correspondingly lower yield. However, if the warhead weight was maintained at 2800 pounds, the bomb weight would probably exceed 3000 pounds. The Los Alamos Scientific Laboratory wanted as large a warhead diameter as possible, while Sandia hoped that the diameter could be kept to a minimum to ease external carriage problems.

This discussion was continued in the September 17, 1954 meeting of the TX-Theta Committee. Weapon diameters from 20 to 35 inches were examined, together with five general shapes. As indicative of the penalties created by external carriage, it was noted that a store with a diameter of 30 inches and a weight of 3000 pounds could be carried by the F-100C. If this weight were increased by 500 pounds, the ceiling of the aircraft would be reduced 500 feet and its range shortened 20 nautical miles. The drag of such an external store was almost 20 percent that of the airplane, and this drag increased about 30 percent if the bomb diameter were increased 5 inches.

(b)(3)

Delivery studies had been made by Sandia.

(b)(1), (b)(3)

The use of a safe-separation timer to provide adequate aircraft escape time after release was recommended.[5]

(b)(1), (b)(3)

(b)(1), (b)(3)

The reasons behind this proposal were that missiles could accommodate warheads up to 44 inches in diameter, but this size was incompatible with external carriage on most aircraft. External aircraft carriage considerations dictated that a bomb with a diameter close to 30 inches be used, and having a structure that could withstand lug and sway brace loads. Additionally, in view of the present circular error inherent in missiles, it was felt advisable to provide a missile warhead with the highest possible yield.[7]

This proposal was forwarded to the Santa Fe Operations Office November 17. 1954.

(b)(1), (b)(3)

It would be compatible with the missiles intended as carriers for the XW-5 Warhead, although some minor warhead compartment modifications might have to be made.

(b)(1), (b)(3)

(b)(1), (b)(3)

This was followed by another letter, March 24, 1955, noting that production interest would depend on the yield attained.[9]

(b)(1), (b)(3)

A meeting was held June 6, 1955, with representatives of the University of California Radiation Laboratory and Los Alamos present, and resulted in a suggestion that Livermore produce the weaponized version of the XW-27.

(b)(1), (b)(3)

(b)(1), (b)(3)

The use of an unboosted primary was discussed in a teletype from the Radiation Laboratory to the Division of Military Application July 1, 1955.

(b)(3)

The shape selected was a reduced-scale Mk 15, with a diameter of 30-1/4 inches and a length of 115 inches, and was chosen due to the proven ballistic and fuzing characteristics of the Mk 15.

(b)(1), (b)(3)

Santa Fe Operations Office notified the Division of Military Application July 13, 1955, that the XW-27 case design posed extensive new engineering problems, and that any predicted time scales would have to be viewed with somewhat less than normal confidence. However, the Radiation Laboratory and Sandia were hopeful of freezing the design by January 1, 1956.[15]

The bomb weight would be kept to a minimum. It would be internally carried in the Air Force's B-47, B-52 and B-66; and in the Navy's AJ, A3D, A3J and P6M. A surface-burst contact fuze was required, which could be selected in flight as the primary burst option, or rendered inoperable prior to flight. The height of burst in the air-burst option would be as near one fireball radius above the target as possible.[18]

The Division of Military Application wrote to Santa Fe Operations Office September 13, 1955, requesting that the Radiation Laboratory and Sandia proceed jointly in the XW-27 program. An operational availability date of October 1957 was desired, provided that this could be met without interference to other programs.[19] Subsequently, September 23, 1955, Santa Fe Operations Office authorized full-scale development for the TX-27 internally carried bomb and the XW-27 warhead programs.[20]

(b)(1), (b)(3)

(b)(1), (b)(3)

It was felt that the bomb design could be released in April 1957, with early production about one year later. The bomb requirements would not adversely affect the nuclear performance of the warhead. The bomb might have a maximum diameter of 30-1/4 inches, an overall length of about 125 inches, and a weight of 3300 pounds. Since the case would be relatively weak, strong handling points would have to be provided.[22]

Sandia notified Field Command December 22, 1955, that the Military Characteristics for the TX-27 designated the same carrying aircraft as for the TX-15, with the exception of the A3J. This similarity in diameter and length of the two weapons had prompted studies aimed at use of the TX-15 suspension system with as little change as possible. It would be necessary to reinforce a large portion of the weapon, and the effect of this reinforcement on weapon yield would have to be determined.

(b)(1), (b)(3)

The Services were requested to submit requirements for aircraft bomb suspension, both for a drop-test program and to allow evaluation of the case design from the standpoints of strong areas and structural requirements.[23]

By early 1956, it had been decided that thermal batteries would be used. It was felt that a barometric fuze would be suitable for the air-burst option. A safe-separation device would be necessary, since some of the aircraft designated as carriers would release bombs at low altitudes.

A trajectory arming device would be included to minimize the possibility of detonation during ground handling or takeoff accidents. The use of air scoop, differential pressure, ram pressure, spin, or roll integration had been considered, and a squib-initiated differential-pressure device being developed for the TX-28 appeared promising. A mechanical clock timer, also being designed for the TX-28, could be used if a timer were required, but its contacts closed only for a 3-second period and continuous closure would have to be provided by a hold-down device. A manually adjustable baroswitch, used in the TX-15, should be suitable for arming and firing, and would provide a close-arming capability.[24]

(b)(1), (b)(3)

The impact fuze was tested to determine whether rain or hail would cause premature or accidental operation.

(b)(1), (b)(3)

The number and location of the contact-fuze elements were slightly changed, to provide better impact response. Sled tests were felt to be unnecessary, and were canceled.[32]

Report SC3776(TR), Proposed Ordnance Characteristics of the TX-27 Weapon, was discussed in the June 27, 1956 meeting of the Special Weapons Development Board. The weapon was described as an internally carried, free-fall bomb,

30-1/4 inches in diameter, 128 inches long, and about 3200 pounds in weight. The weapon consisted of a nose case, warhead, fuze compartment, rear case section with fins, and split band joining the fuze and warhead sections. All compartments were sealed against the weapon environment, with the exception of the split-band and rear-case areas which ~~contained~~ contained no critical components. The weapon could be carried in the Air Force B-47, B-52 and B-66; and the Navy AJ, A3D, A3J and P6M. The A3J application involved replacement of the weapon tail by two fuel tanks, each 30 inches in diameter and 100 inches long, and the overall length of this configuration was about 300 inches.[33]

Meanwhile, difficulty had been encountered in trying to reduce the weight of the weapon. The Military Liaison Committee, on July 5, 1956, noted that a weight increase of 300 pounds over the military characteristics could be tolerated, but would be accepted only on an interim basis.

(b)(1), (b)(3)

Sandia and the Radiation Laboratory jointly reported to the Division of Military Application August 10, 1956, that it would not be possible to reduce the weight of the warhead to 2800 pounds and maintain the yield, and an increase of 100 pounds was mandatory.

(b)(1), (b)(3)

Compatibility problems were also given attention. Multiple carriage of the TX-27 Bomb in the P6M and A3D aircraft was proposed. The bomb fin span precluded carriage of more than one weapon in the A3D, and Sandia investigated the possibility of reducing this fin span. Suitable shapes were tested in the wind tunnel, and it was felt that the fins could be satisfactorily contained within a box whose sides were tangent to the major diameter of the bomb, although the bomb length would have to be increased to 142 inches over its current 125 inches.[36]

Studies had been made of suitable shapes for external carriage, and one with a diameter of 30-1/4 inches, length of 250 inches, and weight of about 3300 pounds was suggested. It was found that this shape was suitable for use with the F-101, F-107, F-108 and RB-47, but was not compatible with the A4D.

Performance degradation, even with semisubmerged carriage, would reduce the top speed of the F-101 approximately 100 knots and that of the F-107 about 20 knots, with the range of both aircraft being shortened some 100 nautical miles. Carriage on the RB-47, using fuselage elbow pylons, would reduce airplane performance about 5 knots and would affect the range slightly.[37]

By early October 1956, wind-tunnel tests of the 125-inch shape had indicated that this configuration was fairly stable. However, the barometric pressure ports would have to be located in the rear case between the fins. This location could not be used on the A3J, as the weapon tail would be replaced by the fuel tanks.

Since a barometric port common to both configurations was desirable, studies were made of a modified Mk 16 shape 142 inches long, having a small box fin, and it was found that a common baro port could be developed. Test data indicated that a spoiler band at Station 82, which was required for the 125-inch shape, was also suitable for the longer case. A change to the longer length would thus provide compatibility with the B-57 and allow multiple-carriage for the A3D and B-66.[38] Air Force requirements for external carriage were canceled October 12, 1956, when the F-101 and RB-47 were eliminated, but the bomb length was left at 142 inches.[39]

Provision for both sling and lug suspension was requested in mid-1956, to provide added operational flexibility.[40] Sling suspension had already been designed, and Sandia subsequently provided removable lugs. The Air Force deleted all TX-27 carriers, except the B-47 and B-52, in December 1956, and these used sling suspension only.[41] However, the Navy required lug suspension for the A3D, and the capability was left for this application.[42]

(b)(1), (b)(3)

The Mk 27 Mod 0 Bomb was design released in May 1957 and achieved production in October 1958. Report SC4091(TR), Description and Status Report at Design Release of the TX-27 Bomb, was presented to the August 21, 1957 meeting of the

(b)(3)

The signal that triggered the high-voltage battery squibs had to be received about 2-1/2 seconds before weapon detonation, to permit charging the X-unit.[48]

The operating sequence of the TX-27 Bomb was as follows: The selector switch in the aircraft was moved to either the air-burst or the ground-burst position, thus placing the low-voltage arm/safe switch in operating position. As the bomb was released, pullout wires activated pulse generators, and this brief pulse of power was applied to a transformer. This pulse transformer had two primary windings, either of which could supply enough energy to fire all the battery squibs. One transformer secondary was connected to a squib-operated monitor switch that fired simultaneously with the battery squibs. This monitor switch provided a simple continuity test for the battery condition; if the switch was open, the batteries had not been activated.

(b)(3)

If air-burst option had been selected, weapon detonation occurred when the firing baroswitches closed. This firing was accomplished by pulsing the trigger transformer, thus operating the thyratrons, causing the gap to break down, and connecting the output of the X-unit capacitors to the detonators of the primary. The output of the primary then compressed the secondary and initiated the fusion reaction.

If ground burst option had been selected, the impact crystal network, operating through the secondary of the saturable core transformer, supplied a voltage pulse to the thyratrons which, in turn, fired the X-unit. If a ground burst signal had been given to the transformer, with the core having been driven to saturation in a given direction, and then the air-burst signal supplied, the weapon would not fire, as there would not be enough change in flux to pulse the transformer. As the bomb continued to fall in its trajectory, however, there would be a detonation when it struck the ground, since the contact burst signal would fire the circuit. In the event the air-burst signal did not operate properly, the ground burst signal would provide backup. The contact fuze network could be disconnected for contact preclusion.[49]

The Division of Military Application sent a teletype to Albuquerque Operations Office, June 22, 1959, noting that manual operation of the arm-safe switch was required and suggesting that action be taken to provide a safer design.[50] Sandia proposed a change, September 28, 1958, which would replace the arm-safe switch with a ready-safe design, operable only by remote control. This would decrease the possibility of sabotage or willful destruction of the Mk 27.[51] The proposal was accepted and resulted in creation of the Mk 27 Mod 1 Bomb.

Sandia subsequently proposed another change, October 21, 1960, which would replace a squib actuated switch in the Mk 27 Bomb and Warhead with a switch that was solenoid operated.[52] It had been found that recent developments in communication transmitters had resulted in higher radio frequency energies being used. This amount of energy, it was felt, might activate the squib switch.[53]

The change was incorporated and resulted in development of the Mk 27 Mod 2 Bomb and the Mk 27 Mod 1 Warhead. Report SC4925(WD), Final Evaluation of the

The adaption kit would permit storage for a period of at least 5 years, and be capable of reliable operation after being installed in the missile for 75 days. The weight of the adaption kit would be a minimum, with the gross weight of kit and warhead not exceeding 3000 pounds.[58]

On August 12, 1955, Sandia submitted a proposed scope of work for the development of the adaption kit for the XW-27/REGULUS I. The first kit would be available for flight testing in March 1956, and complete design release would be in January 1957.[59] This scope of work was approved August 26, 1955.[60]

Early design studies showed that all the possible configurations of the XW-27 which was acceptable from the physics standpoint would result in interference with the REGULUS I air scoop. Agreements were reached to modify the air scoop.[61]

Sandia informed the Bureau of Ordnance September 2, 1955, that the development of a continuously adjustable safe-separation timer would require 3 months of development effort. If, however, the timer requirements could be revised to specify only a capability for either 2 or 10 minutes, the complexity of the device would be reduced, and development time and cost would be saved.[62] This suggestion was adopted.[63]

A radar fuze had been proposed for air burst, but Sandia noted that the required 600-foot accuracy in burst height could be attained with a barometric fuze. This fuze would eliminate any electronic countermeasures problem, simplify assembly and preflight procedures, and reduce weapon support.[62]

The operational characteristics of the XW-27 Warhead required that nuclear and electrical arming be performed shortly before weapon burst. This obviated the need for command arming, since arming would not occur until the weapon was definitely committed. This requirement would also eliminate the need for automatic arming at the end of safe-separation time.[62]

Details of the adaption kit now became firm. Thermal batteries would provide power to charge the X-unit. The primary would be gas-boosted, and the adaption kit

would supply signals to arm and initiate warhead operation. The fuze would be baroswitch-operated, with contact crystals furnishing backup. This fuze would also be capable of accepting radio-command arming and firing signals.

The safe-separation timer would be started by closure of an acceleration switch at missile launch. Additional safety would be provided by a device to connect the thermal battery to the X-unit only after the arming signal had been received. The warhead dimensions were 30-1/4 inches in diameter, 70-1/2 inches in length, and 2800 pounds in weight.

By the end of 1955, a close-arming concept had been adopted, to minimize premature detonation by activation of the impact crystals through enemy antiaircraft fire. This was accomplished by setting the arming baroswitch to operate only a short distance above the firing baroswitch.

(b)(3)

Sandia discussed the adaption kit for the XW-27/REGULUS December 23, 1955. Two missile flight profiles were described. The first was a high-altitude flight at 35,000 feet to the target area, with the missile descending to the target in a vertical dive. Arming and firing of the warhead would take place during this dive, and would be accomplished by the adaption-kit fuze. The missile was also to be capable of flight at low altitudes, and would be flown horizontally over the target at the desired burst height. Arming and firing would be accomplished by command signals sent over the missile guidance system.

(b)(3)

The adaption kit would include the fuzing system and the supports for the warhead and fuzing system in the missile. The fuzing system would have several new features. These included an acceleration-sensitive switch in place of a lanyard-operated switch as in previous designs, thereby eliminating the requirement for pullout wires. A safe-separation timer would provide two preset time intervals of 2 and 10 minutes, either of which could be selected just prior to launch. This option selection, previously accomplished by arming plugs, would be by selector

switch located on the launch panel. The system would be designed for a long-term ready-weapon capability, possibly 18 months under semicontrolled environmental conditions.[65]

By early 1956 the fuzing system was taking shape. The acceleration-sensitive switch would prevent inadvertent charging of the X-unit during storage and while the weapon was being readied for use.[66] This switch contained two sets of air pistons, operated by the launch acceleration, which would close a set of contacts when the warhead was subjected to a 4 g-second impulse. The contacts were spring-loaded, so that a force less than 1-1/2 g's would not close the contacts.

The safe-separation timer contained two sets of motor-driven gear and cam assemblies which closed electrical switches at the end of the timing intervals. One pair of switches closed at the end of 2 minutes, and the other at the end of 10 minutes. Timer action was started by missile-launch action.

The high-voltage thermal batteries for charging the X-unit were isolated by a squib-operated arm switch. During the safe-separation interval, power was kept from the warhead arming and firing circuits by the acceleration switch and the safe-separation timer.

(b)(3)

which controlled the pressure altitude at which the switches would close. An odometer, built into the knob, allowed the firing altitude to be read directly. Another set of four switches, wired into an arming network, was factory-adjusted to close at a specified altitude above the firing network. This furnished close arming, regardless of fuze setting.[67]

For the ground-burst option, the arming baroswitch closed at the arming altitude, with the firing baroswitch being disconnected from the circuit. The X-unit trigger circuit received a firing signal from the impact crystal network in the missile nose.

Sandia notified the Bureau of Aeronautics October 31, 1956, that the XW-27/REGULUS I flight tests, which were launched from Pt. Mugu, California, and impacted in the water at Salton Sea Test Base, had been highly successful. The Sandia-designed items were ready for certification, and the flight-test program would be completed with the seventh flight.[69,70]

The design release of the W-27/REGULUS I program was issued March 27, 1957.[71] This included the adaption kit and all test and handling equipment, with the exception of one item that was released in late April 1957.[72]

The Military Liaison Committee notified the Atomic Energy Commission July 3, 1957, that the Navy's operational-availability-date objective for the XW-27/REGULUS I adaption kit was October 1957, which matched the availability date of the warhead. However, production of the adaption kit had lagged the warhead time scales, and since kit hardware would not be available until February 1958, the warhead would be delayed until this date.[73] The warhead date was then slipped several months.[74]

Report SC4165(TR), Final Engineering Evaluation of the Mk 27 Mod 0 REGULUS I Warhead Application, was presented by Sandia to the April 23, 1958 meeting of the Special Weapons Development Board. The Board accepted the report for forwarding to the Division of Military Application.[75,76]

In the meantime, some work had been done on the REGULUS II application. Santa Fe Operations Office placed this program in full development January 18, 1956, as the first tactical REGULUS II missile was to be available by September 1957.[77] A proposed scope of work for the flight-test program was originated by Sandia, including 11 flights from Edwards Air Force Base, California.[78] However, the program was subsequently canceled.

RASCAL Warhead Application

The RASCAL was an air-to-surface, rocket-powered, supersonic missile with a range of about 90 nautical miles. The missile was 4 feet in diameter and 32 feet long, with one set of four fins near the nose and another set at the tail. The missile was designed and built by the Bell Aircraft Company for the Air Force. Its name was formed from the term RAdar SCAnning Link.

The missile was considered for XW-27 application in mid-1955. Some concern was created by the limitation imposed by the usable length of the warhead compartment in the missile, which was 77 inches. The location of the missile's air scoop was changed, along with modifications to the warhead support structure, adaption-kit components, and the main missile power supply, to avoid nuclear mass discontinuity problems.[14]

Enough progress had been made along these lines so that Sandia suggested to the Air Force Special Weapons Center November 30, 1955, that the XW-5-X1 Warhead could be canceled for application to the RASCAL, leaving the XW-27 as the sole warhead requirement.[79] This proposal was accepted, and early flight tests were made in the fall of 1956. An application design release was issued in January 1957, with the complete engineering release being made January 22, 1958.[80]

Report SC4164(TR), Final Engineering Evaluation of the Mk 27 Mod 0 GAM-63A (RASCAL) Warhead Application, was presented to the April 23, 1958 meeting of the Special Weapons Development Board.

(b)(1), (b)(3)

The Board accepted the report for forwarding to the Division of Military Application.[75,81]

a streamlined fighter plane with a maximum diameter of slightly over 4 feet, length of 39 feet, and swept-back wings. It was launched by a single, solid-propellant rocket, which accelerated the missile until the turbojet engine could attain sufficient thrust to sustain flight.

(b)(1), (b)(3)

The XW-27/MATADOR project was canceled in November 1956.[88]

SHAPE 96 Application

(b)(3)

Santa Fe Operations Office authorized full development work on the XW-27/F-101 project May 24, 1955.[89]

Design study indicated, however, that the Shape would require major modification to support the warhead and, since difficulties were being encountered with Shape 96, the project was canceled in March 1956.[90]

RESTRICTED DATA

SECRET

Glossary of Mk 27 Terms

Adaption Kit -- Those items peculiar to the warhead installation less the warhead; namely, the arming and fuzing system, power supply, and all hardware, adapters and the like, required by a particular installation.

Air Force Special Weapons Center -- That element of the Air Force Systems Command having to do with compatibility testing of nuclear devices with aircraft. Located at Kirtland Air Force Base, Albuquerque, New Mexico.

Albuquerque Operations Office -- The local office of the Atomic Energy Commission (AEC) concerned with the operations of Sandia Corporation.

Arming -- The act of arming a weapon, that is, preparing it for firing.

Assistant Secretary of Defense -- Created by Department of Defense Directive, June 30, 1953, as part of DOD reorganization. Handles research and development activities of the DOD.

(b)(1), (b)(3)

SECRET

UNCLASSIFIED
RESTRICTED DATA

(b)(3)

Department of Defense -- The Armed Forces, i.e., the Army, Navy and Air Force.

Design Review and Acceptance Group -- A Military committee established to review the design of a specific weapon.

Detonators -- Devices containing bridge wires which, when subjected to an electrical current, burn rapidly and act as a match to apply a flame to various points on the outer surface of the high-explosive sphere.

Deuterium -- The hydrogen isotope of mass number 2.

Division of Military Application -- An AEC office that functions as liaison between the Military and weapons designers and producers.

Dump -- The point in its trajectory at which a guided missile "dumps" or turns toward the target.

(b)(1), (b)(3)

Field Command -- The local office of the Armed Forces Special Weapons Project located on Sandia Base, Albuquerque, New Mexico.

Firing System -- The electrical system of the weapon that produces and applies a high-voltage current to the detonators.

Fissile Material -- Material capable of being fissioned.

Fuzing System -- The system that

g -- Force equal to one unit gravity.

Gas Boosting -- The technique of increasing the yield of a nuclear device by introducing deuterium-tritium gas into the implosion process to increase the fission activity.

Ground Burst -- Detonation at or very close to the surface of the bomb or target.

High Explosive Sphere -- The ball of high explosive that surrounds the nuclear primary and produces the implosion effect when detonated.

(b)(1), (b)(3)

JATO -- Named for Jet-Assisted Take-Off. A jet device initially designed to assist heavily loaded aircraft to take off from short runways. Used as a boosting device in missile launching.

Joint Chiefs of Staff -- An Army-Navy-Air Force group to determine policy and to develop joint strategic objectives of the Armed Forces.

Kilogram -- A metric weight approximating 2.2 pounds.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Kilovolt -- 1000 volts.

(b)(1), (b)(3)

Megaton -- A measure of yield of a large weapon. One megaton is the equivalent of 1,000,000 tons of high explosive.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense committee established to advise and consult with the AEC on all matters relating to military applications of atomic energy.

Nautical Mile -- A naval measurement of length. One nautical mile is equivalent to 6076.1033 feet, or the length of 1 minute of arc (1/21,600) of a great circle of the earth.

Neutron -- An uncharged particle of slightly greater mass than the proton.

(b)(1), (b)(3)

(b)(3)

Teapot -- A less-than-full-scale test series held at the Nevada Test Site. Series of 14 tests, starting February 18 and ending May 15, 1955.

Thermal Battery -- A battery whose electrolyte is in a solid state while inactive. To activate, heat is applied to this electrolyte, melting it and putting the battery into active output condition.

Thermonuclear -- Two-stage reaction, with a fission device exploding and starting a fusion reaction in light elements.

Thyratron -- A grid-controlled electron tube.

Transonic -- A speed approximating that of Mach 1.0, the speed of sound; or 738 miles per hour at sea level.

Tritium -- The hydrogen isotope of mass number 3.

Two-Stage -- Combination of fission and fusion action in a weapon.

TX-Theta Committee -- A committee established to guide the development of thermonuclear weapons.

University of California Radiation Laboratory -- A nuclear design organization located at Livermore, California.

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent uranium-238; the rest is uranium-235.

Warhead -- As used in this history, a weapon carried to the target by missile.

X-Unit -- ~~A high-voltage transformer.~~ A device used to provide high voltage to the weapon detonators.

7/63	Early production of Mk 28 Mod 4 Warhead achieved.

Mk 28/MACE Warhead Installation

1/18/56	Production authorization released for Mk 28/MATADOR. Missile later redesignated MACE.
3/14/56	Military characteristics for Mk 28/MACE approved by Military Liaison Committee.
6/59	Mk 28 Mod 0 Warhead released for use in the MACE missile.
8/62	Final evaluation report of MACE Warhead Application released.

Mk 28/HOUND DOG Warhead Installation

1/58	Feasibility study of warhead installation for HOUND DOG missile requested.
5/16/58	Assistant Secretary of Defense selects XW-28 Warhead for installation in HOUND DOG missile.
5/28/60	Initial authorization for restricted use of Mk 28/HOUND DOG issued.
12/61	General release of Mk 28/HOUND DOG authorized.
3/62	Final evaluation of Mk 28 Mod 1 Warhead in HOUND DOG missile released.

Details of the TX-28 design then became firm. The weapon center section would be a partially contoured cylindrical case, 20 inches in diameter and 49 inches long, and capped at each end with a hemisphere.

(b)(1), (b)(3)

One fin could be folded, to provide ground and aircraft carriage clearance. The fin control mechanism would be powered by explosive squibs, actuated at bomb release from the carrying aircraft. The feasibility of the 3-hook suspension was felt to be doubtful, in view of possible warhead requirements, and this design was dropped.[18]

The design of the TX-28 Prime fuze was also proceeding rapidly. One-shot, explosively actuated switches would control such actions as preheat current switching, timer output selection, high-voltage thermal-battery arming, ground- or air-burst selection, contact-fuze arming, timer-motor starting, trajectory-arm-switch pressure-port sealing, gas-boost initiation, and even thermal-battery monitoring. These switches were small, light, resistant to shock, and could be used extensively.[19]

Operational safety would be increased by the installation of a switch which would close after experiencing the normal trajectory of a free-fall bomb. This switch was a dual-chamber baroswitch. One chamber was sealed when the bomb was released from the aircraft, and the second measured the pressure increase as the bomb fell toward its target.

(b)(1), (b)(3)

Choice of air burst or contact option would be made before takeoff, and the operations required of the pilot prior to release of the weapon were reduced to 3, as compared to about 15 required for other tactical fuzes. Basic design emphasis was placed on simplification, miniaturization and operational safety.

The length of the bomb was 170 inches, thus resulting in a fineness ratio of 8.5, and the weight was estimated to be 1700 pounds. The bomb was divided into three parts: Nose (containing fuze), center section (containing primary and secondary), and tail. The weapon could be shortened for internal carriage

interval timer, 28 volts was applied to the squib transformers of the high-voltage thermal-battery pack. This activated the batteries and initiated charging of the X-unit capacitor bank. The firing circuits of the radar sets were also armed at this time.

When the bomb fell to an altitude above the target equal to the range setting in the radar system, a firing relay in the radars connected 28 volts to the weapon firing circuit and triggered the spark gap. The 2500-volt output of the X-unit then discharged through the gap, firing the weapon detonators.

If the radar system failed, ground impact operated the contact crystals unless contact preclusion had been selected before aircraft takeoff. Operation of the contact crystals produced a voltage which triggered the thyratron in the weapon trigger circuit. A capacitor then discharged through a pulse transformer in the weapon firing circuit and triggered the spark gap.

Contact option was made by selecting the Ground option on the aircraft monitor and control system. This action operated the electrical safing switches in the weapon. At bomb release, thermal batteries were activated, interval timer started, pressure ports of the fixed differential pressure switch sealed, fin extending mechanism actuated (for externally carried bombs only), and the contact option switch which disconnected the radar fire line was operated. The pullout switch closed, applying the 28-volt output of the thermal batteries to the fuzing system.

(b)(1), (b)(3)

At the end of the safe-separation time preset on the interval timer, a switch closed to operate the contact arm switch and start charging the X-unit. At ground impact, the crystal net produced a voltage which triggered a thyratron and subsequently the spark gap. The X-unit output then discharged through the gap, firing the weapon detonators.[31]

use of shock-mitigating materials. It was felt possible to design a bomb to withstand laydown impact shocks of 200 to 300 g's.[33]

Design progress was discussed in the October 26, 1955 meeting of the Special Weapons Development Board. Sandia stated that both parachutes and rotochutes had been tested. Existing parachute designs were not able to absorb the shock created by a bomb released at high speeds, and a stronger parachute was being designed. Rotochutes could not properly handle the bomb weight. Retrorockets had been considered, but these imposed operational restrictions.

Sandia had recorded promising shock-cushioning tests of honeycomb material in drops from 14- and 80-foot towers, and was erecting a 300-foot tower, which would produce vertical impact velocities of about 135 feet per second, about that of a parachute-retarded bomb. Devices to be tested would be guided by a slanting cable which would allow application of side forces, such as those caused by wind effects or tumbling of the weapon after target impact.[22]

Early in 1956, Sandia analyzed the delivery characteristics of several low-level, retarded-delivery systems. The study concluded that a retarded trajectory version of a nonimpact-resistant TX-28 type weapon was desirable, and that this device could be produced well before the true laydown weapons then under development. The study results were subsequently presented to the Tableleg Committee (investigating the laydown design) in April 1956 as an interim method of achieving many of the laydown weapon objectives about 2 years in advance of the true laydown weapon.[34]

Results of the study were incorporated in Report SC3860(TR), Design Study of *a Drogue-Retarded TX-28 Weapon Family. The study proposed finless external* and internal retarded versions of the TX-28 free-fall bombs, but without the capability of inflight selection of retarded or free-fall delivery.[34]

After presentation to the Air Force of proposals for retardation of TX-28 weapons, the Air Force requested the capability of inflight selection of retarded or free-fall delivery. Preliminary investigation showed that this could be accomplished by using a small pilot parachute for stabilization in

If the radar system failed, impact with the ground operated the contact crystals unless contact preclusion had been selected before takeoff. Operation of these crystals produced a voltage that triggered a thyratron, discharging a capacitor through the spark gap, and firing the X-unit and detonators.

In the contact option, preflight setting of the option plug to the contact backup position was made. The contact option was then chosen in flight by turning to the Ground position on the aircraft monitor and control. At bomb release, arming was accomplished in the same manner as for the air-burst option, and aircraft power through the pulse plug fired an option switch which disconnected the radar fire lines from the weapon firing circuit. At the end of safe-separation time, a squib switch in the trigger circuit was actuated, closing the line between a thyratron tube and the gap firing transformer, thus arming the contact system. At surface impact, the crystal network produced a voltage that detonated the bomb.

Contact bursts could be precluded by preflight setting of the option plug to the contact-preclude position. The arming and firing sequence was the same as for the air-burst option with contact backup, except that the contact system was never armed.[35]

Report SC4150(TR), Description and Status at Complete Design Release of the TX-28-X1 Bomb, was presented to the August 20, 1958 meeting of the Special Weapons Development Board.[46] The Mk 28 EX Mod 1 was 160 inches long, weighed 2020 pounds, and provided external carriage and free-fall delivery. The Mk 28 IN Mod 1 was 96.4 inches long, weighed 1940 pounds, and provided internal carriage and free-fall delivery. The Mk 28 RE Mod 1 was 166 inches long, weighed 2140 pounds, and provided retarded delivery.

(b)(1), (b)(3)

The radar was capable of reliable operation at all weapon attitude angles up to and including 60 degrees from the vertical. For larger angles, the system reliability was lowered. There were two fuzing limitations. A 10-second timer setting was the minimum available for safe separation, and

impractical, and the system was changed to include a motor-operated arm/safe switch, which completed the circuit between the pulse generator and the low-voltage thermal battery. This change permitted the bomb to be dropped in a safe condition without initiating the power supplies.

The TX-28-X2 was design released in April 1959 and Report SC4253(TR), Status at Complete Design Release of the TX-28-X2 Bomb, was presented to the October 21, 1959 meeting of the Special Weapons Development Board.[53] The forward section of the bomb was 20 inches in diameter and the tail section was 22 inches in diameter. The bomb was 132 inches long, weighed 2265 pounds and could be internally carried in B-47 and B-52 bombers.

(b)(3)

The Mk 28 Retarded Internal Bomb achieved production in June 1960. The design consisted of the Mk 28 Mod 1 Warhead, Mk 28 Mod 2 Fuze, and Mk 28 Mod 0 Retarded Internal Shape Components.

Before loading the weapon in the delivery aircraft, the safe condition of the system was checked with a built-in continuity monitor and a safe-separation timer was set. After loading, the aircraft monitor and control power was turned on with the option select switch in Safe position. This released a solenoid interlock on the Ready/Safe switch, which was then turned to Ready.

In flight, and preferably after entering enemy territory, ground burst was selected on the aircraft control. When this was done, two arming/safing switches operated to the Arm Position. One of these switches connected the pulse-generator output to the initiating circuits of the low-voltage thermal-battery pack, and the other connected the high-voltage battery to the X-unit capacitor bank. If air burst was inadvertently selected, the system would function in the same way and automatically selected ground burst.

At bomb release, pullout rods actuated pulse generators. Output pulses from these generators initiated low-voltage thermal batteries and started deployment

timers. As the bomb entered the airstream, differential pressure across the aerodynamic fences caused a pressure switch to close, connecting the 1-second contacts in the deployment timers to the activation circuits of the detonators, safe-separation timer, and switch pack. At the end of 1 second, timer contacts closed, connecting the 12-volt sections of the low-voltage thermal batteries to the components noted.

The detonators fired and initiated a length of mild detonating fuse which blew off the rear cover plate. As the cover plate fell away, it deployed the pilot parachute, which in turn deployed the first-stage chute. Explosive motors in the safe-separation timer fired and unlatched the starting mechanism, which allowed the timer to begin timing. The switch pack operated and connected the 28-volt sections of the low-voltage batteries to the safe-separation timer contacts, trigger-circuit option switch, and explosive motors in the reservoir and valve assembly.

(b)(3)

The actuators fired, causing the bolt to fracture. The lug release ring separated from the lug mounting plate. The lugs pivoted, releasing risers of the first-stage parachute. As the first-stage chute fell away, it deployed the second-stage chute.

At the end of safe-separation time, contacts of the safe-separation timer closed and connected the 28-volt output of the low-voltage batteries to the primaries of the high-voltage-battery actuating transformers. The high-voltage thermal batteries activated and charged the X-unit capacitor bank.

Since existing radars would require more space than could be provided, and a smaller unit, being designed, would not be immediately available, a timer fuze was proposed. This was rejected, after study, as it involved possible errors in release altitude and variations in the time of fall. A baroswitch with a fixed burst altitude was then considered, and felt to be acceptable.

A remotely settable baroswitch was required, in order to permit the Strategic Air Command to control the fixed setting at depot level with available equipment. To eliminate the need for preflight selection of retarded or free-fall delivery mode, a system was proposed in which the release altitude was sensed and used to select the mode automatically. If the release was made at high altitudes, the weapon would drop free fall; with a low-altitude release, a retardation system would be used. The two altitude ranges were separated by a region in which weapon releases were not anticipated. For free-fall drops, the aircraft would be at or near its maximum altitude and, for retarded drops, the altitude would be only a few thousand feet above sea level. Several available switches could be used. The firing signal would be supplied by a timer in the laydown option and by contact crystals for surface detonation.

An operational requirement for the TX-28-X3 was issued by the Deputy Director for Research and Engineering August 18, 1960, and early production requested in February 1962. The design would be capable of being released 500 feet above the target, be carried internally in the B-47 and B-52 aircraft, and have a full-fuzing option.[58]

The bomb nose was provided with 8 inches of crushable honeycomb to absorb laydown shocks. A fourth parachute was added to the Mk 28 Retarded Internal Bomb design to provide free-fall stabilization and reduce baro sensing errors, and the design was released October 1961.

Report SC4534(WD), Proposed Ordnance Characteristics of the TX-28-X3 Bomb, was accepted by Field Command October 12, 1961. The Mk 28 FI Bomb consisted of a Mk 28 Mod 2 Warhead, Mk 28 Mod 3 Fuze, and Mk 28 Mod 0 Full-Fuzing

1/62	Early production of Mk 28 Mod 2 Warhead achieved.
12/62	Early production of Mk 28 Mod 3 Warhead achieved.
7/63	Early production of Mk 28 Mod 4 Warhead achieved.

Mk 28/MACE Warhead Installation

1/18/56	Production authorization released for Mk 28/MATADOR. Missile later redesignated MACE.
3/14/56	Military characteristics for Mk 28/MACE approved by Military Liaison Committee.
6/59	Mk 28 Mod 0 Warhead released for use in the MACE missile.
8/62	Final evaluation report of MACE Warhead Application released.

Mk 28/HOUND DOG Warhead Installation

1/58	Feasibility study of warhead installation for HOUND DOG missile requested.
5/16/58	Assistant Secretary of Defense selects XW-28 Warhead for installation in HOUND DOG missile.
5/28/60	Initial authorization for restricted use of Mk 28/HOUND DOG issued.
12/61	General release of Mk 28/HOUND DOG authorized.
3/62	Final evaluation of Mk 28 Mod 1 Warhead in HOUND DOG missile released.

The missile warhead weight would be a minimum and not exceed 2800 pounds. The warhead would be compatible with the Air Force MATADOR, RASCAL, SNARK and NAVAHO; the Navy REGULUS and TRITON; and the Army REDSTONE. Manually and electrically operated arming and safing components would be incorporated, as well as a device to monitor the safe or armed condition of the warhead.

(b)(1), (b)(3)

The TX-Theta Committee, meeting September 17, 1954, reported that the weight and diameter of externally carried bombs had a significant effect on the range and speed of carrying aircraft.

(b)(3)

The TX-Theta Committee again met November 5, 1954.

(b)(1), (b)(3)

The TX-Theta Committee wrote to Santa Fe Operations Office, November 17, 1954, proposing that two different weapons be built, a large-diameter XW-27 Warhead compatible with missile carriers and a smaller diameter TX-28 Bomb to be externally and internally carried on high performance fighter bombers.

(b)(1), (b)(3)

It was hoped that suitable weapon designs could be released by early 1957, with production occurring in the mid-part of that year.[5]

Sandia discussed the design of the TX-28 in the December 1, 1954 meeting of the Special Weapons Development Board. The maximum length of the bomb was felt to be 250 inches, although shorter lengths suitable for internal carriage

(b)(1), (b)(3)

It was hoped that a bomb considerably smaller in diameter and weighing less than 2800 pounds could be developed and, if necessary, some reduction in yield would be acceptable. The Military Liaison Committee requested that a diameter of about 25 inches be considered, and this study was assigned high priority.[8]

(b)(1), (b)(3)

(b)(1), (b)(3)

Also, due to radioactive decay, the amount of tritium in the gas decreased steadily and had to be periodically replaced. This replacement could be most conveniently done if the boosting gas was in a replaceable reservoir.

(b)(3)

By April 1955, Sandia was designing the TX-28 fuze. Barometric fuzing had been considered, but rejected due to the wide variety of delivery systems and consequent variation in delivery velocities. This variation made it difficult to develop a satisfactory pressure-sensing system, and the use of different field settings for each mission would have negated a ready-weapon concept. A timer was considered, and would have allowed a slightly better minimum release angle in LABS (Low-Altitude Bombing System) missions and a

Details of the TX-28 design then became firm. The weapon center section would be a partially contoured cylindrical case, 20 inches in diameter and 49 inches long, and capped at each end with a hemisphere.

(b)(1), (b)(3)

One fin could be folded, to provide ground and aircraft carriage clearance. The fin control mechanism would be powered by explosive squibs, actuated at bomb release from the carrying aircraft. The feasibility of the 3-hook suspension was felt to be doubtful, in view of possible warhead requirements, and this design was dropped.[18]

The design of the TX-28 Prime fuze was also proceeding rapidly. One-shot, explosively actuated switches would control such actions as preheat current switching, timer output selection, high-voltage thermal-battery arming, ground- or air-burst selection, contact-fuze arming, timer-motor starting, trajectory-arm-switch pressure-port sealing, gas-boost initiation, and even thermal-battery monitoring. These switches were small, light, resistant to shock, and could be used extensively.[19]

Operational safety would be increased by the installation of a switch which would close after experiencing the normal trajectory of a free-fall bomb. This switch was a dual-chamber baroswitch. One chamber was sealed when the bomb was released from the aircraft, and the second measured the pressure increase as the bomb fell toward its target.

(b)(1), (b)(3)

Choice of air burst or contact option would be made before takeoff, and the operations required of the pilot prior to release of the weapon were reduced to 3, as compared to about 15 required for other tactical fuzes. Basic design emphasis was placed on simplification, miniaturization and operational safety.

The length of the bomb was 170 inches, thus resulting in a fineness ratio of 8.5, and the weight was estimated to be 1700 pounds. The bomb was divided into three parts: Nose (containing fuze), center section (containing primary and secondary), and tail. The weapon could be shortened for internal carriage

UNCLASSIFIED

(b)(3)

Report SC3691(TR), Proposed Ordnance Characteristics of the TX-28 Atomic Weapon, was presented to the October 26, 1955 meeting of the Special Weapons Development Board.[22] This report noted that the tail could be rotated in increments, thus allowing the fin to fold either up or down. A fuze access panel was provided, to allow access to the high-voltage thermal cells.

A pulse pullout plug fired squib switches when the bomb was released from the carrying aircraft. The case of this plug failed at a break line, and the two sections of the plug separated. The safety ground was broken during the motion of the plug and a pulse of 28-volt aircraft power applied to the squib lines. The safe-separation timer was dual-channeled for reliability. Both long and short times were available, and both times could be set in each channel.[23]

(b)(1), (b)(3)

Santa Fe Operations Office accepted these yield designations, but requested

identify the internal-carriage version.[27] Sandia noted that omission of yield or configuration designation would mean broad applicability to all yields or configurations.[28]

(b)(1), (b)(3)

The Mk 28 EX Mod 0 and Mk 28 IN Mod 0 were design released June 1957, and early production achieved in August 1958. Sandia presented Report SC4092(TR),

interval timer, 28 volts was applied to the squib transformers of the high-voltage thermal-battery pack. This activated the batteries and initiated charging of the X-unit capacitor bank. The firing circuits of the radar sets were also armed at this time.

When the bomb fell to an altitude above the target equal to the range setting in the radar system, a firing relay in the radars connected 28 volts to the weapon firing circuit and triggered the spark gap. The 2500-volt output of the X-unit then discharged through the gap, firing the weapon detonators.

If the radar system failed, ground impact operated the contact crystals unless contact preclusion had been selected before aircraft takeoff. Operation of the contact crystals produced a voltage which triggered the thyratron in the weapon trigger circuit. A capacitor then discharged through a pulse transformer in the weapon firing circuit and triggered the spark gap.

Contact option was made by selecting the Ground option on the aircraft monitor and control system. This action operated the electrical safing switches in the weapon. At bomb release, thermal batteries were activated, interval timer started, pressure ports of the fixed differential pressure switch sealed, fin extending mechanism actuated (for externally carried bombs only), and the contact option switch which disconnected the radar fire line was operated. The pullout switch closed, applying the 28-volt output of the thermal batteries to the fuzing system.

(b)(1). (b)(3)

At the end of the safe-separation time preset on the interval timer, a switch closed to operate the contact arm switch and start charging the X-unit. At ground impact, the crystal net produced a voltage which triggered a thyratron and subsequently the spark gap. The X-unit output then discharged through the gap, firing the weapon detonators.[31]

use of shock-mitigating materials. It was felt possible to design a bomb to withstand laydown impact shocks of 200 to 300 g's.[33]

Design progress was discussed in the October 26, 1955 meeting of the Special Weapons Development Board. Sandia stated that both parachutes and rotochutes had been tested. Existing parachute designs were not able to absorb the shock created by a bomb released at high speeds, and a stronger parachute was being designed. Rotochutes could not properly handle the bomb weight. Retrorockets had been considered, but these imposed operational restrictions.

Sandia had recorded promising shock-cushioning tests of honeycomb material in drops from 14- and 80-foot towers, and was erecting a 300-foot tower, which would produce vertical impact velocities of about 135 feet per second, about that of a parachute-retarded bomb. Devices to be tested would be guided by a slanting cable which would allow application of side forces, such as those caused by wind effects or tumbling of the weapon after target impact.[22]

Early in 1956, Sandia analyzed the delivery characteristics of several low-level, retarded-delivery systems. The study concluded that a retarded trajectory version of a nonimpact-resistant TX-28 type weapon was desirable, and that this device could be produced well before the true laydown weapons then under development. The study results were subsequently presented to the Tableleg Committee (investigating the laydown design) in April 1956 as an interim method of achieving many of the laydown weapon objectives about 2 years in advance of the true laydown weapon.[34]

Results of the study were incorporated in Report SC3860(TR), Design Study of a Drogue-Retarded TX-28 Weapon Family. The study proposed finless external and internal retarded versions of the TX-28 free-fall bombs, but without the capability of inflight selection of retarded or free-fall delivery.[34]

After presentation to the Air Force of proposals for retardation of TX-28 weapons, the Air Force requested the capability of inflight selection of retarded or free-fall delivery. Preliminary investigation showed that this could be accomplished by using a small pilot parachute for stabilization in

the free-fall mode and by using the pilot chute to deploy a large drogue parachute for the retarded mode. Selection of delivery option would be accomplished by minor modification of the aircraft monitor and control system.[35]

The Air Force Special Weapons Center wrote to Field Command August 3, 1956, advocating the drogue parachute program, as this would increase bomb-delivery accuracy. The existing bomb tail would not be large enough to hold the drogue parachute, and a new tail would have to be provided. This increase in size would aggravate ground and aircraft clearance problems, and might make it impossible to allow room for stabilizing fins. Thus, a decision to use this type of delivery might have to be made before final bomb assembly.[36]

The Division of Military Application was notified September 26, 1956 that a drogue-retarded TX-28 weapon family would not delay or compromise the rest of the project. The weapon system would be a little complex, due to the number of different units required to make the TX-28 a universal-use weapon. However, it was felt that production and stockpiling problems would not be too formidable.[37,38]

Production authorization for the drogue-retarded Mk 28 was issued January 17, 1957 by the Division of Military Application.[39] The design was named the TX-28-X1, and a stockpile date of June 1958 was requested.[40] The tail would incorporate two parachutes; a small, stabilizing chute for free-fall deliveries and a larger chute for retarded deliveries. When the large chute was used, the section containing the small chute would be jettisoned.[41]

The design would have the capability of inflight selection of retarded or free-fall option in a single, streamlined shape suitable for external carriage by the designated aircraft and for internal carriage by the A3D, and no changes to the aircraft monitor and control system would be required. No requirement was established for an internally carried retarded TX-28 as it was felt that this would unacceptably complicate weapon design, stockpiling and logistics.[42]

If the radar system failed, impact with the ground operated the contact crystals unless contact preclusion had been selected before takeoff. Operation of these crystals produced a voltage that triggered a thyratron, discharging a capacitor through the spark gap, and firing the X-unit and detonators.

In the contact option, preflight setting of the option plug to the contact backup position was made. The contact option was then chosen in flight by turning to the Ground position on the aircraft monitor and control. At bomb release, arming was accomplished in the same manner as for the air-burst option, and aircraft power through the pulse plug fired an option switch which disconnected the radar fire lines from the weapon firing circuit. At the end of safe-separation time, a squib switch in the trigger circuit was actuated, closing the line between a thyratron tube and the gap firing transformer, thus arming the contact system. At surface impact, the crystal network produced a voltage that detonated the bomb.

Contact bursts could be precluded by preflight setting of the option plug to the contact-preclude position. The arming and firing sequence was the same as for the air-burst option with contact backup, except that the contact system was never armed.[35]

Report SC4150(TR), Description and Status at Complete Design Release of the TX-28-X1 Bomb, was presented to the August 20, 1958 meeting of the Special Weapons Development Board.[46] The Mk 28 EX Mod 1 was 160 inches long, weighed 2020 pounds, and provided external carriage and free-fall delivery. The Mk 28 IN Mod 1 was 96.4 inches long, weighed 1940 pounds, and provided internal carriage and free-fall delivery. The Mk 28 RE Mod 1 was 166 inches long, weighed 2140 pounds, and provided retarded delivery.

(b)(1), (b)(3)

The radar was capable of reliable operation at all weapon attitude angles up to and including 60 degrees from the vertical. For larger angles, the system reliability was lowered. There were two fuzing limitations. A 10-second timer setting was the minimum available for safe separation, and

(b)(3)

Firing was then accomplished, either by radars ranging for air-burst or by impact fuzes at time of contact.[47]

Mk 28 Retarded Internal (RI) Bomb

In late March 1958, the Strategic Air Command noted that enemy defenses had increased to the point where all high-altitude target bombing approaches were being abandoned in favor of an "on-the-deck" approach. It was pointed out that no thermonuclear bomb currently available could be released at altitudes of 1500 feet or less, and it was requested that the Mk 28 be modified to allow it to be so released. The carrying aircraft would be the B-47, and some degradation in ballistic performance would be acceptable, if an immediate capability could be provided.[48]

Subsequently, April 17, 1958, the Assistant Secretary of Defense requested the Atomic Energy Commission to develop a maximum-drogued Mk 28 Bomb. This design would require a new afterbody, parachute and fuze, and would be supplied in the form of a conversion kit that could be applied to any stockpiled Mk 28. This TX-28-X2 design would have a 40-second down-time from a release altitude of 1500 feet. The weapon would be fuzed for contact burst only, and would be capable of being carried in the B-47, B-52 and possibly the B-66.[49]

Design work was immediately started.[50] Initial verbal requirements were for a "fail-safe" system in which the weapon would not arm and fire in the event of parachute failure. However, on the basis of informal guidance, a "fail-arm" system, which would arm and fire regardless of proper parachute operation, was considered and specified in early August 1958. No external power would be required, except for a prerelease arming signal. At release, a pulse of power from a generator would initiate fast-rise thermal batteries that would subsequently furnish all the bomb power requirements.[51]

The design required that the pullout cables be located in the bomb tail and the fuze in the bomb nose, and external fairings were installed to connect

these two sections and provide room for interconnecting cabling. The bomb was armed or safed by the aircraft monitor and control system, with high-voltage safing being accomplished by a motor-driven switch, and low-voltage safing by a manually operated control. A check of the safe or ready condition of the weapon could be made by a hand-cranked continuity tester whose output current was less than that required to fire any bomb component.

The initial approach to the design of the fail-arm fuze was to provide automatic selection of arming time compatible with proper parachute operation.

(b)(3)

Since the retarded time of fall was 50 seconds, the thermal batteries required comparatively long life. No existing battery was suitable, and work was started on a new design. As information on the deceleration signature of the parachute deployment system would not be available until late in the program, it was decided to provide an alternate system. In this design, closing of a trajectory arm switch fired an explosive device that locked-in the arming power. The closure of this device completed the circuit from the low-voltage thermal battery to the arming components, and thus a highly reliable design was needed. This was furnished by an existing switch activated by either of two squibs and having a fusible disc that would melt in a fire and disconnect the switch from the weapon system. The Military subsequently requested that the bomb system be designed to fail-safe, to assure safe-separation time for carrier aircraft, and a safe-separation timer was added.[52]

Initially, it had been planned to install removable safing pins in the pulse-generator pull rods, and the Air Force was to provide a manual system to remove these pins after the weapon was airborne. This was found to be

impractical, and the system was changed to include a motor-operated arm/safe switch, which completed the circuit between the pulse generator and the low-voltage thermal battery. This change permitted the bomb to be dropped in a safe condition without initiating the power supplies.

The TX-28-X2 was design released in April 1959 and Report SC4253(TR), Status at Complete Design Release of the TX-28-X2 Bomb, was presented to the October 21, 1959 meeting of the Special Weapons Development Board.[53] The forward section of the bomb was 20 inches in diameter and the tail section was 22 inches in diameter. The bomb was 132 inches long, weighed 2265 pounds and could be internally carried in B-47 and B-52 bombers.

(b)(3)

The Mk 28 Retarded Internal Bomb achieved production in June 1960. The design consisted of the Mk 28 Mod 1 Warhead, Mk 28 Mod 2 Fuze, and Mk 28 Mod 0 Retarded Internal Shape Components.

Before loading the weapon in the delivery aircraft, the safe condition of the system was checked with a built-in continuity monitor and a safe-separation timer was set. After loading, the aircraft monitor and control power was turned on with the option select switch in Safe position. This released a solenoid interlock on the Ready/Safe switch, which was then turned to Ready.

In flight, and preferably after entering enemy territory, ground burst was selected on the aircraft control. When this was done, two arming/safing switches operated to the Arm Position. One of these switches connected the pulse-generator output to the initiating circuits of the low-voltage thermal-battery pack, and the other connected the high-voltage battery to the X-unit capacitor bank. If air burst was inadvertently selected, the system would function in the same way and automatically selected ground burst.

At bomb release, pullout rods actuated pulse generators. Output pulses from these generators initiated low-voltage thermal batteries and started deployment

timers. As the bomb entered the airstream, differential pressure across the aerodynamic fences caused a pressure switch to close, connecting the 1-second contacts in the deployment timers to the activation circuits of the detonators, safe-separation timer, and switch pack. At the end of 1 second, timer contacts closed, connecting the 12-volt sections of the low-voltage thermal batteries to the components noted.

The detonators fired and initiated a length of mild detonating fuse which blew off the rear cover plate. As the cover plate fell away, it deployed the pilot parachute, which in turn deployed the first-stage chute. Explosive motors in the safe-separation timer fired and unlatched the starting mechanism, which allowed the timer to begin timing. The switch pack operated and connected the 28-volt sections of the low-voltage batteries to the safe-separation timer contacts, trigger-circuit option switch, and explosive motors in the reservoir and valve assembly.

(b)(3)

The actuators fired, causing the bolt to fracture. The lug release ring separated from the lug mounting plate. The lugs pivoted, releasing risers of the first-stage parachute. As the first-stage chute fell away, it deployed the second-stage chute.

At the end of safe-separation time, contacts of the safe-separation timer closed and connected the 28-volt output of the low-voltage batteries to the primaries of the high-voltage-battery actuating transformers. The high-voltage thermal batteries activated and charged the X-unit capacitor bank.

Since existing radars would require more space than could be provided, and a smaller unit, being designed, would not be immediately available, a timer fuze was proposed. This was rejected, after study, as it involved possible errors in release altitude and variations in the time of fall. A baroswitch with a fixed burst altitude was then considered, and felt to be acceptable.

A remotely settable baroswitch was required, in order to permit the Strategic Air Command to control the fixed setting at depot level with available equipment. To eliminate the need for preflight selection of retarded or free-fall delivery mode, a system was proposed in which the release altitude was sensed and used to select the mode automatically. If the release was made at high altitudes, the weapon would drop free fall; with a low-altitude release, a retardation system would be used. The two altitude ranges were separated by a region in which weapon releases were not anticipated. For free-fall drops, the aircraft would be at or near its maximum altitude and, for retarded drops, the altitude would be only a few thousand feet above sea level. Several available switches could be used. The firing signal would be supplied by a timer in the laydown option and by contact crystals for surface detonation.

An operational requirement for the TX-28-X3 was issued by the Deputy Director for Research and Engineering August 18, 1960, and early production requested in February 1962. The design would be capable of being released 500 feet above the target, be carried internally in the B-47 and B-52 aircraft, and have a full-fuzing option.[58]

The bomb nose was provided with 8 inches of crushable honeycomb to absorb laydown shocks. A fourth parachute was added to the Mk 28 Retarded Internal Bomb design to provide free-fall stabilization and reduce baro sensing errors, and the design was released October 1961.

Report SC4534(WD), Proposed Ordnance Characteristics of the TX-28-X3 Bomb, was accepted by Field Command October 12, 1961. The Mk 28 FI Bomb consisted of a Mk 28 Mod 2 Warhead, Mk 28 Mod 3 Fuze, and Mk 28 Mod 0 Full-Fuzing

Since retarded laydown was desired, the release altitude must be below 12,000 feet pressure altitude, assuring that the baroswitch was closed at release. Laydown was achieved by releasing the weapon at an altitude no lower than 500 feet above the terrain and no higher than 2400 feet, to allow the bomb to reach the ground before the end of the 79-second interval.

At release, the pullout generator was actuated to initiate the low-voltage thermal batteries and start the sequential timer. As the 12-volt sections of the low-voltage batteries came up to voltage (a maximum of 0.7 second after initiation), the differential pressure inducers and the baro ports operated. If the release velocity was greater than the required minimum, the differential pressure induced across the pressure inducers caused the pressure switches to close and connected a set of timer contacts to the activation circuits of the fuse switches. About 0.7 second after pullout-generator actuation, the timer contacts closed and connected the 12-volt sections of the low-voltage thermal batteries to a set of switches and a 60-second pyrotechnic timer, through the closed contacts of the pressure switches and the baroswitch, and to two of the six detonators. These detonators initiated mild detonating fuse which removed the rear cover plate from the bomb. As the cover plate blew off, the 4-foot pilot parachute deployed a 16-1/2-foot-diameter parachute. The 12-volt sections of the low-voltage batteries were meanwhile connected to the contacts of the timer and to the neutron generators.

Approximately 2.4 seconds after pullout generator actuation, a second set of timer contacts closed and connected the 12-volt sections of the low-voltage thermal batteries to a second pair of detonators. These ignited a length of mild detonating fuse which initiated deployment of the second-stage chute. The time of fall from 500 feet above the target altitude was about 10 seconds.

(b)(3)

initiated, but those in the parachute jettison device were activated. The 4-foot pilot chute deployed the 16-1/2-foot chute, and both the 16-1/2- and 64-foot chutes were then jettisoned, and a 30-inch drag chute deployed by action of the jettison device. At the time the chutes were jettisoned, switches were activated, connecting the first set of contacts of the timer to the fuzing circuit. At closure of this timer, explosive switches in the switch pack and the option switches were operated.

(b)(3)

Upon reaching the burst altitude, the baroswitch closed, applying a firing signal to the trigger circuit. If the air-burst option failed, the bomb was detonated at impact by a signal from the impact crystals.

In the free-fall contact option, the fuzing and firing system operated as in the free-fall air-burst option, with some exceptions. Before release, the aircraft monitor and control was placed to the Ground position. This action completed all circuits as in the free-fall air-burst option, except that the firing baro was not connected into the fuzing circuits. At impact, a fire signal was supplied by the impact crystals.[60]

Mk 28 Warhead

(b)(1), (b)(3)

The warhead design was released in June 1957 and achieved early production in August 1958. The Mod 0 Warhead contained an internal initiator.

The Mod 1 Warhead was equipped with external initiation and the first production date was May 1960. The Mod 2 Warhead was strengthened against laydown usage, and the design was first produced in January 1962.[61] The Mod 3 Warhead contained Category A permissive arming links and was first made in [62]

Ground compatibility tests of warhead with missile were begun in April 1959 and satisfactorily completed in July 1959. Flight tests were conducted between late 1959 and early 1961. Restricted use of the Mk 28 Mod 0 Warhead in the HOUND DOG was authorized May 28, 1960, and a general release was issued December 1961.

Report SC4572(WD), Final Engineering Evaluation Report of GAM-77 (HOUND DOG) Application of the Mk 28 Mod 1 Warhead, was dated March 1962. The missile was a turbojet-powered, air-to-ground strategic missile designed for launch from B-52 aircraft. Each airplane could carry two missiles. The missile was of mid-wing canard configuration and had an underslung pod for the jet engine. It had a major fuselage diameter of 28.5 inches, length of 42.5 feet, and major wingspan of 12.3 feet. The missile maximum velocity was Mach 2.1 and its range 650 nautical miles.

Development responsibility for the arming and fuzing system was assigned to North American Aviation. The warhead itself was 20 inches in diameter, 60 inches long, and weighed 1645 pounds with internal initiator and 1675 pounds with external initiator.

The missile had five basic delivery profiles. The high-altitude missile cruise mode could be initiated from either high or low altitude. The same option was available for the low-level cruise mode. A free-fall bomb-drop capability provided an emergency delivery option in the event of missile system malfunction.

The first three steps in the arming and fuzing sequence were independent of missile flight mode. Prior to launch, aircraft power was switched to the safing-switch motors which drove the switches to the Arm position. At launch, pullout-switch closure applied either normal missile power or emergency battery power to the safe-separation timer. The duration of timer operation was dependent on prelaunch setting. At the end of safe-separation interval, timer contacts closed and applied power to either the arming and fuzing baroswitches or the autonavigator. For high-altitude cruise and free-fall modes,

Glossary of Mk 28 Terms

(b)(1), (b)(3)

Department of Defense -- The Armed Forces; i.e., the Army, Navy and Air Force.

Detonator -- Explosive device which, when initiated by the X-unit, ignites the lens charges of the high-explosive sphere.

Deuterium -- The hydrogen isotope of mass number 2.

(b)(1), (b)(3)

Joint Chiefs of Staff -- A group composed of the Chiefs of Staff of the Army, Navy and Air Force to determine policy and develop joint strategic objectives of the Armed Forces.

Kilogram -- A metric weight approximately 2.2 pounds.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

(b)(1), (b)(3)

Mach -- A measure of speed. Mach 1.0 is the speed of sound, or 738 miles per hour at sea level.

Megaton -- A measure of yield of a large weapon. One megaton is the equivalent of 1,000,000 tons of high explosive.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

Nautical Mile -- A naval measurement of length. One nautical mile is equivalent to 6076.1033 feet, or the length of 1 minute of arc (1/21,600) of a great circle of the earth.

Neutron -- An uncharged particle of slightly greater mass than the proton.

Operation Castle -- See Castle.

Operation Greenhouse -- See Greenhouse.

Operation Redwing -- See Redwing.

Operation Teapot -- See Teapot.

Permissive Arming Link -- A device designed to delay or prevent unauthorized personnel from being able to arm and detonate a weapon full scale.

Pit -- The metal sphere at the center of an implosion bomb which received the nuclear capsule when it is inserted.

Plutonium-239 -- A radioactive heavy element, atomic number 94.

Primary -- A fission bomb that acts as the source of energy to start the secondary of thermonuclear reaction of a two-stage device.

Proton -- The nucleus of the atom of the light isotope of hydrogen. It has a unit positive charge of electricity.

Radar -- Named for Radio Detecting and Ranging. Radars emit a pulse of high-frequency energy and measure the time lapse from that transmission to receipt of a reflected electrical "echo" from an object. This time measurement determines the distance of the object from the transmitting antenna of the radar.

Redwing -- A full-scale nuclear series of 17 tests held at the Pacific Proving Grounds from May 4 to July 21, 1956.

Reservoir -- A container for deuterium-tritium boosting gas.

Ribbon Parachute -- A parachute having a set of ribbons in place of a solid canopy. This type of parachute provides less severe deceleration on deployment.

Rotochute -- A device to slow down the rate of descent of a free-fall weapon. Consists of counterrotating propeller blades which absorb energy.

(b)(1), (b)(3)

(b)(1), (b)(3)

Tactical -- Use of a weapon against troops or concentrations of war materiel.

Teapot -- A less-than-full-scale test series held at the Nevada Test Site. Series of 14 tests, starting February 18 and ending May 15, 1955.

Thermal Battery -- A battery whose electrolyte is in a solid state while inactive. To activate, heat is applied to this electrolyte, melting it and putting the battery into active output condition.

Thermonuclear -- Two-stage reaction, with a fission device exploding and starting a fusion reaction in light elements.

Thyratron -- A grid-controlled electron tube.

Tritium -- The hydrogen isotope of mass number 3.

Two-Stage -- Combination of fission and fusion action in a weapon.

TX-Theta Committee -- A committee established to guide the development of thermonuclear weapons.

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent uranium-238; the rest is uranium-235.

X-Unit -- A device used to provide high voltage to the weapon detonators.

Yield -- The measure of the effect of a nuclear detonation compared to the effect of an explosion of TNT.

Timetable of Mk 30 Events

Late 1952	Project Heavenbound suggests use of BOMARC missile for atomic warhead carriage.
4/53	Joint Chiefs of Staff issue military requirements for adaptation of XW-12 Warhead to the Air Force BOMARC.
5/15/53	Field Command issues proposed military characteristics for an air defense weapon of 22 inches diameter.
1/5/54	Military Liaison Committee requests consideration of warhead for Navy TALOS missile.
4/13/54	AEC accepts responsibility for developing 22- and 30-inch diameter air defense atomic warheads.
5/4/54	Division of Military Application forwards approved military characteristics for 22- and 30-inch warheads to Santa Fe Operations Office.

(b)(1), (b)(3)

3/12/55	Assistant Secretary of Defense requests AEC to develop XW-30/ TALOS-W missile warhead.
8/29/56	Sandia presents proposed ordnance characteristics report of XW-30/ TALOS-W to Special Weapons Development Board.

(b)(1), (b)(3)

1/58	Mk 30 Mod 0 Warhead released for production.
4/4/58	Assistant Secretary of Defense requests application of Mk 30 Warhead to BOMARC missile.
6/6/58	Feasibility study reports that warhead will be compatible with BOMARC.
Early 1959	Mk 30/BOMARC Warhead program canceled.
4/15/59	Albuquerque Operations Office issues development authorization for XW-30-X1 Tactical Atomic Demolition Munition.

9/25/59	Division of Military Application requests incorporation of environmental sensing devices in Mk 30 Warhead.
11/60	Mk 30 Mod 1 Tactical Atomic Demolition Munition design released.
12/60	Mk 30 Mod 1 achieves production.
3/61	Mk 30 Mod 2 Warhead, with environmental sensing devices, design released.
6/61	Mk 30 Mod 2 Warhead achieves production.
4/64	Mk 30 Mod 3 Warhead, with 5-tumbler combination lock, design released. Later canceled.

History of the Mk 30 Warhead

The Mk 30 was one of three air-defense missile warheads designed concurrently, the others being the Mk 25 and Mk 31. As developing technology permitted the weight of nuclear devices to be reduced and their yields to be increased, it became possible to consider use of nuclear warheads for defense against mass aircraft raids. It was necessary to investigate the effects of high altitudes on operation of these warheads and in late 1952 a feasibility study of air-defense nuclear devices, called Project Heavenbound, was conducted by the Air Force Special Weapons Center. Project Heavenbound determined that BOMARC, a ground-to-air missile being developed by Boeing Aircraft Company for the Air Force, could carry an atomic warhead and, in April 1953, the Joint Chiefs of Staff issued a military requirement for the adaptation of the XW-12 Warhead to BOMARC.[1]

Field Command subsequently prepared a set of proposed military characteristics for an air-defense weapon with a diameter of 22 inches May 15, 1953.[2] These characteristics were largely written around the XW-12 Warhead, although it was evident that this design made inefficient use of nuclear material. The Bureau of Ordnance, then developing a rocket to carry the XW-12, felt that a warhead with higher performance should be chosen, and noted that the missile itself was not entirely suitable.[3]

The Los Alamos Scientific Laboratory could not guarantee an immediate improvement in the XW-12 nuclear design, and Sandia stated that components capable of operating at high altitudes would have to be devised. Sandia was developing a new X-unit which would be operationally suitable but too bulky to fit into the TALOS-W, a Navy missile also being considered for air defense use, and it was felt that any reduction in the size of this X-unit might unduly restrict its electrical characteristics. The warhead could be enclosed in a pressuretight missile compartment, or a sealed warhead provided, but either approach would require a lengthy development program.[4]

As study continued, it became apparent that the XW-12 would require major redesign before it could be used at high altitudes. The proposed military characteristics described an atomic warhead compatible with several delivery vehicles. (b)(3)

not be extended without basic redesign. The new X-unit, which might be able to operate at extremely high altitudes, was undergoing feasibility study, but cables and detonators would also have to be designed for high-altitude operation.[4]

The TALOS-W Coordination Committee met April 2, 1954, and discussed four possibilities for air-defense warheads. The first would be to use the existing XW-12 Warhead with its inherent limitations. The second would be to make minor modifications to this warhead which would improve its altitude capabilities. The third would be to design an interim 22-inch/500-pound warhead using XW-12 components. The fourth would be to design an ultimate 22-inch/350-pound warhead and provide new components.[10]

This information was forwarded to the Military Liaison Committee and, April 13, 1954, the Atomic Energy Commission accepted responsibility for developing both a 22- and a 30-inch-diameter warhead. (b)(1), (b)(3)

The Division of Military Application forwarded the approved military characteristics for 22- and 30-inch antiaircraft warheads to the Santa Fe Operations Office May 4, 1954. (b)(1), (b)(3)

This warhead was to have maximum nuclear efficiency and be compatible with the TALOS-W missile. (b)(1), (b)(3)

Doubt was expressed, however, that a 350-pound warhead could be achieved in a diameter of 22 inches.[13]

3. They would have to be easily maintained. Since personnel handling these weapons would have minimum training, the technical skill for maintenance and operation would have to be kept to a minimum.

The Board noted that the Air Force BOMARC could be used in a national perimeter defense, in conjunction with an early-warning detection system having a range of 250 to 500 miles. However, the BOMARC would not become operational until 1959, and the Navy TALOS-W would be available during the interim period. Both missiles would be capable of carrying either an XW-12 or a 22-inch air-defense warhead.[18]

(b)(1), (b)(3)

The Assistant Secretary of Defense wrote to the Atomic Energy Commission March 12, 1955, requesting development of an XW-30/TALOS-W missile-warhead. The Navy was the cognizant agency, with normal Armed Forces Special Weapons Project relationships. Department of Defense approval of work beyond design release was withheld, pending outcome of further development work.[20]

By early May 1955, the nuclear design of the XW-30 Warhead was determined. The active material was plutonium, and would be fashioned into thin, concentric shells. The design would be boosted with deuterium-tritium gas, externally initiated, and the pit would be sealed to permit operation at high altitudes. It was felt that production could be achieved by early 1958.[21]

The Military Liaison Committee wrote to the Atomic Energy Commission June 15, 1955, stating that the Department of Defense had agreed to increase the overall weight of

the XW-30 to 500 pounds. Concerning the suggestion that the XW-25 Warhead be applied to the TALOS-W, it was noted that the missile had been designed with the XW-30 Warhead in mind, and that any change in warhead would require redesign of the missile.[22]

The Bureau of Ordnance wrote to Santa Fe Operations Office August 12, 1955, noting that development of both missile and warhead would be accelerated if some of the adaption-kit components were developed by Sandia. Sandia was requested to develop an arming and safing system, selectable contact fuze for a surface-to-surface sea capability, contact fuze for surface-to-air missiles striking a target, and a system to dispose of erratic missiles.[23] The responsibility for providing contact fuzes was later transferred to the missile development agency.[24]

By late 1955, considerable progress had been made on the XW-30 nonnuclear design. The warhead length had been fixed at 48.62 inches and the weight at 487 pounds.
(b)(1), (b)(3)

The TALOS-W Coordination Committee met December 14, 1955. Warhead design had been completed, and flight-test units would be available by July 1956. If the required 10 flights could be completed by the end of 1956, the warhead design could be released in January 1957, early production achieved in late 1957, and operational availability in July 1958.[25]

Sandia presented Report SC3842(TR), Proposed Ordnance Characteristics for the XW-30/TALOS-W Warhead Installation, to the August 29, 1956 meeting of the Special Weapons Development Board. The report noted that the TALOS-W was a rocket-launched, ramjet-propelled, supersonic, beam-riding missile designed to intercept and destroy enemy aircraft. It had a range between 2-1/2 and 100 miles, service ceiling of 70,000 feet, and maximum speed of 2400 feet per second (almost Mach 2.5). The total weight of the missile was 7700 pounds, including a solid-fuel booster that separated from the missile some 5 seconds after launch. The missile was 30 inches in diameter and 32 feet long and had a stabilizing wing with a span of 9 feet.

(b)(3)

Meanwhile, consideration had been given to applying the Mk 30 Warhead to the BOMARC and, on April 4, 1958, the Assistant Secretary of Defense suggested that savings in reactor materials could be realized if the Mk 30 were used in this application in place of the XW-40 originally proposed. It was requested that a joint feasibility study be conducted with the Air Force.[36]

The report on this study was released June 6, 1958. (b)(1), (b)(3)

Sandia notified the Division of Military Application, January 2, 1959, that a new warhead development program would be needed to provide BOMARC compatibility, and this would require 3 years before operational availability. This was due to the introduction of several new factors since issuance of the feasibility report, including an extension of armed life, provision of a dudding mechanism, and a more reliable self-destruction system.

It had also been determined that adaptation of the Mk 30 Warhead to the BOMARC was not so simple as initially believed. The lateral type of mounting required by the missile necessitated repackaging of all warhead components, redesign of sphere case, and modification to the electrical system.[38] In addition, use of internal initiation would increase the amount of tritium required[39] and, after consideration of all these factors, the program was canceled.

The Mk 30 military characteristics were amended in February 1959 to specify an unboosted version to be used in a Tactical Atomic Demolition Munition, and a development authorization was issued by Albuquerque Operations Office April 15, 1959, authorizing the XW-30-X1 TADM program. (b)(1), (b)(3)

(b)(1), (b)(3)

A general request had been made by the Division of Military Application for replacement of 3-tumbler combination locks with 5-tumbler designs, to provide a design more resistant to saboteurs. As a result, development of the Mk 30 Mod 3 Warhead was authorized in April 1964. A study of the costs involved resulted in a later decision to cancel this modification, and the change was never incorporated.[46]

Design Review and Acceptance Group -- A Military committee that absorbed some of the functions of the Special Weapons Development Board.

Deuterium -- The hydrogen isotope of mass number 2.

Development Program Definition -- A report that describes the weapon to be designed and the steps that will be taken in its development.

Division of Military Application -- An AEC office that functions as liaison between the Military and weapons designers and producers.

(b)(1), (b)(3)

Field Command -- The local office of the Armed Forces Special Weapons Project (or Defense Atomic Support Agency), located on Sandia Base, Albuquerque, New Mexico.

Firing System -- The electrical system of the weapon that produces and applies a high-voltage current to the detonators.

Fuze -- A combination of the arming and firing devices of a weapon.

g -- Force equal to one unit gravity.

Gas Boosting -- The technique of increasing the yield of a nuclear device by introducing deuterium-tritium gas into the implosion process to increase the fission activity.

(b)(1), (b)(3)

Joint Chiefs of Staff -- A group composed of the Chiefs of Staff of the Army, Navy and Air Force to determine policy and develop joint strategic objectives of the Armed Forces.

(b)(1), (b)(3)

Reservoir -- A container for deuterium-tritium boosting gas.

Safing -- Putting a weapon in condition such that it cannot fire.

Santa Fe Operations Office -- The local office of the Atomic Energy Commission (AEC) concerned with Sandia operations.

Sealed Pit -- A weapon in which all the nuclear components (except the boosting gas) are permanently installed in place. Designed to eliminate the need for inflight nuclear insertion mechanisms.

Services -- The Department of Defense.

Spark Gap -- An air gap that prevents passage of electrical current. When the gap is ionized, current is conducted.

Special Weapons Development Board -- A joint Military-Sandia board at Sandia Base to provide local guidance on weapons design.

Squib -- A device containing a small powder charge. When detonated, the resulting gas pressure closes a switch or performs a similar action. A light, quick-acting, one-shot device.

Supersonic -- Any speed exceeding that of Mach 1.0, which is the speed of sound, or 738 miles per hour at sea level.

(b)(1), (b)(3)

(b)(1), (b)(3)

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent uranium-238; the rest is uranium-235.

Velocity Switch -- An environmental sensing device whose action depends on the speed environment to which it is subjected.

Warhead -- A weapon carried to the target by missile.

X-Unit -- A device used to provide high voltage to the weapon detonators.

Yield -- The measure of the effect of a nuclear detonation compared to the effect of an explosion of TNT.

Timetable of Mk 31/37 Events

Mid-1953	Development of gas boosting offers possibility of small-diameter atomic devices.
	(b)(1), (b)(3)
4/14/54	Military characteristics for boosted air-defense warheads with diameters of 22 and 30 inches issued.
12/13/54	Army requests that AEC develop Mk 7 and 30-inch-diameter warheads for application to NIKE missile.
1/12/55	Division of Military Application authorizes development of 30-inch-diameter warhead.
3/11/55	Santa Fe Operations Office issues scope of work covering design of adaption kits for XW-7 and 30-inch-diameter warheads for NIKE-B application.
	(b)(1), (b)(3)
6/24/55	Assistant Secretary of Defense requests feasibility study of high-yield warhead for NIKE-B.
8/31/55	Division of Military Application requests development of high-yield warhead for NIKE-B.
	(b)(1), (b)(3)
1/27/56	High-yield XW-37/NIKE-B program approved for development by the Assistant Secretary of Defense.
	(b)(1), (b)(3)
6/27/56	Sandia presents proposed ordnance characteristics of XW-31/37 to Special Weapons Development Board.
9/17/56	XW-31 becomes the XW-31-Y1 and XW-37 becomes the XW-31-Y2. Decision made to use uranium-235 in nuclear assembly of XW-31 rather than composite assembly of uranium-235 and plutonium.

10/18/56 Proposed ordnance characteristics of the XW-31/37 NIKE-B application forwarded to Division of Military Application.

10/25/56 Recommendation made that XW-31-Y2 be authorized for marriage with the HONEST JOHN missile.

11/15/56 NIKE-B nomenclature changed to NIKE HERCULES.

(b)(1), (b)(3)

9/18/57 Design-release report of XW-31 presented to Special Weapons Development Board.

(b)(1), (b)(3)

6/58 Design-release report of NIKE HERCULES adaption kit published.

10/58 Mk 31 Mod 0 NIKE HERCULES becomes operationally available.

10/59 Mk 31 Mod 0/HONEST JOHN becomes operationally available.

6/60 Final evaluation of Mk 31 Mod 0 Warhead published.

6/60 Final evaluation of Mk 31/NIKE HERCULES application published.

Mk 31 Mod 1 (Atomic Demolition Munition)

10/21/58 Military characteristics for the Mk 31 Atomic Demolition Munition issued.

4/15/59 Albuquerque Operations Office issues authorization to proceed with Mk 31 Mod 1 development.

6/60 Design release accomplished.

9/60	Early production started.
12/7/61	Final evaluation report of Mk 31 Mod 1 Munition accepted by Field Command.

Mk 31 Mod 2 Warhead

3/59	Sandia proposes incorporation of handling safety devices in Mk 31 Warheads.
9/59	Military Liaison Committee accepts proposal.
6/62	Mk 31 Mod 2 Warhead design released.
3/63	Early production of Mk 31 Mod 2 Warhead.
9/13/63	Final development report accepted by Field Command.

CROSSBOW Application

9/53	Study of applicable warheads for CROSSBOW missile started.
9/23/54	Marriage program for XW-7/CROSSBOW approved.
11/55	Study report recommends that the XW-31 Warhead replace the XW-7 for the CROSSBOW application.
3/3/56	Assistant Secretary of Defense authorizes development of XW-31 Warhead for use with CROSSBOW.
1/24/57	CROSSBOW application canceled due to missile problems.

RESTRICTED DATA

UNCLASSIFIED

History of the Mk 31/37 Warhead

This program began in mid-1953, when development of gas boosting offered promise that efficient small-diameter atomic devices might be created. (b)(1), (b)(3)

This design would have to meet requirements of immedate readiness, high-g loading, high-altitude functioning, and maximum economy of fissionable material. (b)(1), (b)(3)

Tentative military characteristics had been proposed by the Military Liaison Committee for boosted air-defense warheads with diameters of 22 and 30 inches, and these characteristics were refined and formally released April 14, 1954.[3] The 22-inch-diameter device became the Mk 30, and the 30-inch-diameter design, which will be discussed in this history, became the Mk 31/37.
(b)(1), (b)(3)

The weapon would be able to withstand single-mission flights of 2 hours and a total flight time of 50 hours, and temperatures from -55°F to +165°F. The firing system would be capable of operation at all altitudes from sea level to 100,000 feet. The nuclear insertion system would provide arming within a period of 6 seconds, and safing within 3 seconds. The weapon would be able to remain in a state of functional readiness for a period of at least 30 days.[4]

SECRET
RESTRICTED DATA

UNCLASSIFIED

This 30-inch-diameter warhead was discussed in a meeting of the Joint Committee on NIKE-B Warhead Installations May 12, 1954. It was felt that the XW-7 high-explosive system could be used, and that no safing problems existed. It was noted that this design would result in fewer restrictions on the missile stockpile-to-target sequence than the XW-7 Warhead.[5]

Subsequently, December 13, 1954, the Army requested that both Mk 7 and 30-inch warheads be developed for NIKE application. This request was forwarded to Sandia by Santa Fe Operations Office as interim guidance, although it was noted that formal Military Liaison Committee approval of the 30-inch warhead marriage program had not as yet been received. However, there was a need for this warhead, even though yield, dimensional characteristics, and identification of carriers were not definite, and the program was placed in full development. It was felt that the Military would eventually replace the XW-7 with the 30-inch design. Thus major effort would be placed on the latter, making certain, however, that a suitable warhead would be ready in time to meet the missile availability date.[6]

The Division of Military Application notified Santa Fe Operations Office January 12, 1955, that the Military Liaison Committee directive of April 14, 1954, had only suggested that the 30-inch warhead might be adaptable to the NIKE-B. This was not considered to represent a firm requirement for the missile-warhead combination, but development of the warhead itself was obviously required.[3]

The warhead was discussed in a Special Weapons Development Board meeting January 12, 1955. The principal purpose of the NIKE-B was surface-to-air attack of enemy aircraft, but it was felt that a secondary surface-to-surface mission would be desirable, having either air or contact burst.

It was noted that high accelerations during nuclear insertion and the requirement for an extremely rapid retraction of the capsule on the downward leg of the flight of a malfunctioning missile would tax the capabilities of existing inflight insertion mechanisms. Air motors, powered by bottles of compressed

air, were being studied, as well as a barrel-cam mechanism whose operation was similar to that of a lipstick container.

Since the missile might be required to make rather rapid changes in direction, some of which might increase the angle of attack of the missile to as much as 30 degrees, a zero angle of attack or swivel probe was required to provide an accurate pressure-sensing system. Barometric accuracy was important, both to initiate nuclear retraction as close to the ground as possible in the event of malfunction in the surface-to-air mission, and to provide a fuze for the possible secondary surface-to-surface mission.[7]

A scope of work covering design of adaption kits for both XW-7 and 30-inch warheads was approved by Santa Fe Operations Office March 11, 1955, and the Assistant Secretary of Defense authorized development of a 30-inch-diameter or XW-31/NIKE-B missile-warhead March 12, 1955.[8,9]

(b)(1), (b)(3)

The basic design of the XW-31 Warhead was now firmed up. (b)(1), (b)(3)

A boosted, sealed-pit system would eliminate any need for capsule retraction. First production was predicted for early 1958.

Accurate pressure sensing was a major requirement, to allow the warhead to be armed at the proper point in the trajectory and detonated at a specific altitude. Testing of supersonic missiles had revealed several major sources of error in existing pressure-sensing systems. Any abrupt changes in the direction of missile travel, and these were inherent in NIKE operation, caused errors, since the axis of the probe which formed the inlet to the barometric system would deviate from the direction of air flow, and thus produce unequal pressures under different angular positions.[7] A self-aligning static tube, with the probe mounted on a universal joint, allowing alignment with the airstream, solved this difficulty.

Plumbing-system pressure lags created time-delay errors, and these time lags were aggravated by the total amount of air contained in the system. This was reduced to a minimum by development of baroswitches with an internal volume of 2.7 cubic inches, as compared to 25 cubic inches in similar devices. At the same time, the diameter of the piping was increased, to reduce the effect of skin friction, which delayed system response.

It was found that cylindrical probes were accurate at speeds up to Mach 1.8, but that errors were introduced above this speed. Tapering of the end of the probe to a 1-degree half-angle solved this difficulty and allowed the probe to be calibrated at all airspeeds up to Mach 5.

By June 15, 1955, preliminary layout of the adaption kit for the warhead installation was completed. This included arm/safe switches and low-volume barometric switches for arming and fuzing. These components, with the necessary relays, connectors and wiring would be installed in a sealed container that could be handled as a unit.[12]

nuclear design would be a hollow, gas-boosted system with external initiation. (b)(3)

This latter would conserve plutonium, then in short supply, and avoid the problems of fabricating thin plutonium shells. Flight tests would start in May 1956, design-release date would be March 1957, and operational availability was scheduled for October 1958.[19]

The Division of Military Application notified Santa Fe Operations Office December 19, 1955, that the Army was considering acceleration of the NIKE-B program. The Military Liaison Committee had requested that Mk 7 development be similarly expedited, to assure warhead availability. (b)(1), (b)(3)

It was felt that this latter device would meet a Joint Chiefs of Staff request for a high-yield air-defense warhead.[20]

On January 27, 1956, development of the XW-37/NIKE-B Warhead was authorized by the Assistant Secretary of Defense. Picatinny Arsenal would represent the Army, and applications to the CORPORAL, HONEST JOHN, SERGEANT and atomic demolition munition would be considered at a later date. Coordination of the project was placed in the hands of the NIKE-B Committee.[21]
(b)(3)

The XW-31/37 would be used primarily for perimeter defense of major population areas and, although the missile batteries would be located some distance away, the warheads could be detonated directly over metropolitan centers.[22] (b)(3)

(b)(1), (b)(3)

(b)(3)

(b)(3)

Meanwhile, sled tests of impact devices had indicated that the best design for fast action and positive indication was a double-shell crush switch located in the nose of the weapon, with piezoelectric crystals pulsing a thyratron trigger circuit. This design had been selected for production, and the missile contractor (Douglas Aircraft Company) was developing a suitable nose compartment. Testing of self-aligning probes were in process, but had encountered instrumentation difficulty which was caused by sensitivity of the vibration pressure pickup to mounting orientation.[25]

A formal feasibility report covering the design of an economical, medium-yield warhead was issued June 1, 1956. (b)(1), (b)(3)

(b)(3)

The gas-boosting system would contain a reservoir containing high-pressure gas, squib-operated valve, and associated tubing. A pit vacuum monitoring system would check for existence of leaks which would degrade the yield through atmospheric corrosion of the nuclear material. Provision would be made to detect tritium leakage during storage or handling, since this gas was a health hazard. (b)(1), (b)(3)

Sandia presented Report SC3752(TR), Proposed Ordnance Characteristics of the XW-31/37 (NIKE-B Application) Atomic Warhead Installation, to the June 27, 1956 meeting of the Special Weapons Development Board.[1] (b)(1), (b)(3)

Both warhead and adaption kit were sealed with the cartridge assembly containing most of the adaption-kit components being attached to the warhead.

(b)(1), (b)(3)

An impact switch held two metal rings mounted inside the weapon nose and insulated at points of contact with the skin. When the skin was crushed against the ring at weapon impact, a firing circuit was completed and the warhead detonated. (b)(3)

The Board accepted the report, subject to inclusion of a warhead reliability study. This information was provided and forwarded to the Division of Military Application October 18, 1956.[27]

By July 1956, systems design of the XW-31/37 Warheads had been completed. Four more sled tests had been performed, and the deformation switch was deemed to be completely satisfactory for NIKE-B impact fuzing applications. Sandia meanwhile had recommended that weapons with multiple yields be assigned a single Mark designation, and that a suffix be used to indicate the yield. This proposal was accepted by Field Command September 17, 1956; the XW-31 thus becoming the XW-31-Y1 and the XW-37 becoming the XW-31-Y2.[28] At this time it was definitely decided to use uranium-235, rather than a composite nuclear system, to conserve plutonium.

Meanwhile, some thought had been given to compatibility of the warhead with the HONEST JOHN missile. The Joint Committee on HONEST JOHN Warhead Installations met October 25, 1956. A longer range version of this missile had been proposed, and a recommendation made that the higher yield XW-31 Warhead be mated to this missile rather than the Mk 7. The longer range HONEST JOHN would have a higher acceleration, and it was felt that the XW-31 would be better able to resist this acceleration.[29] The recommendation was accepted and forwarded to Washington.

NIKE-B missile nomenclature was changed to NIKE HERCULES November 15, 1956, and the intercept capability of the NIKE system was increased from 25 to 50 miles. The Mk 7 flight-test program had meanwhile been delayed due to missile problems, and flight tests with the XW-31-Y2 Warhead were rescheduled to January 1957. It was hoped that the eight flights required for warhead certification could be completed before the scheduled design-release date of June 1957.[30]

(b)(1), (b)(3)

Development was requested of all three warhead combinations, and the Department of the Army was designated cognizant agency for the Department of Defense.[31] An operational availability date of July 1959 was desired, but would depend on the availability of nuclear material.[32]

The Joint Committee on HONEST JOHN Warhead Installations met February 7, 1957. The longer-range rocket promised improvements in deflection, altitude and range accuracy. The rocket weight would be reduced by 1000 pounds and the length by 3 feet through use of a new propulsion unit being developed by Redstone Arsenal, and this would increase the rocket range by 15 percent. Picatinny Arsenal was developing an adaption kit, and it appeared that the XW-31 Warhead could be used with either the old or the improved HONEST JOHN.

(b)(1), (b)(3)

The weight would be identical in all yields, as the lighter versions would be ballasted to that of the heaviest. It was felt that the transistorized power supply of the external initiators might cause trouble, due to sensitivity of these transistors to neutron radiation, and Los Alamos agreed to consider use of internal initiation for some of the XW-31 yields. This would simplify development effort, provide operational simplicity, and allow more positive control of time scales.[33]

(b)(1), (b)(3)

(b)(1), (b)(3)

Report SC4099(TR), Description and Status at Complete Design Release of the XW-31 Warhead, was presented to the September 18, 1957 meeting of the Special Weapons Development Board. The warhead was 29.01 inches in diameter, 39.05 inches long, and weighed 920 pounds. The warhead was compatible with both NIKE HERCULES and HONEST JOHN missiles.[40] (b)(1), (b)(3)

The report was subsequently forwarded to the Division of Military Application February 26, 1958.[42] The Mk 31Y2 Warhead design was released in November 1957, when the external initiator became available.[43] Subsequently, external initiators were deleted from the Y1 and Y3 versions, leaving the Y2 with an external neutron generator.[44]

Meanwhile, the Army Air Defense Board had noted that there was a high probability of receiving a premature command signal from the missile guidance system in the surface-to-surface mode. This was a safety hazard, as it disabled the self-destruct system. If the missile was fired straight up, the warhead would be armed and, when it returned, the warhead would detonate at the fuzing altitude.[45]

This problem was discussed in the November 5, 1957 meeting of the Joint Committee on NIKE HERCULES Warhead Installations, and it was decided that the best solution was to install a timer in parallel with the command signal. Since it was desired that this timer not interfere with the reliability of

the primary surface-to-air mission, it should not be incorporated in the guidance-equipment package, and Sandia agreed to place it in the adaption kit. Development of the timer was started immediately, and would be included in the system only when a surface-to-surface plug was installed.[46]

(b)(3)

Meanwhile, difficulties had been encountered on both missile programs. The HONEST JOHN adaption kit slipped 3 months, due to lack of funding.[48] The NIKE HERCULES changed from liquid to solid propellant, and this created difficulties.[49]

(b)(1), (b)(3)

A suitable timer was installed in the warhead, and the guidance computer modified.[50]

Report SC4099(TR), Description and Status at Design Release of the XW-31 Warhead, was released January 1958 by Sandia. This noted that partial design release of the Mk 31 with the Y1, Y2 and Y3 had been accomplished in June 1957, with complete release scheduled for November 1957.[41] (The actual date was March 1958.)

The report noted that the NIKE HERCULES was a two-stage missile, with a solid-propellant booster and sustainer. The sustainer motor ignited when the booster separated (about 35 seconds after launch) and powered the missile for about 32 seconds. After burnout, the missile coasted to the intercept point. Flight duration was between 10 and 200 seconds. The missile was guided throughout its flight after initial boosting.[41]

(b)(1), (b)(3)

Report SC4243(WD), Final Evaluation Report of the Mk 31 Mod 0 Warhead, was published in June 1960. This noted that the sequence of operation was unchanged from that described in the report at design release.[44] On the same date was published Report SC4242(WD), Final Engineering Evaluation of the M75 Adaption Kit and the Mk 31/NIKE HERCULES Application. This noted that the missile was capable of intercepting aircraft formations at ranges in excess of 50 miles and above 80,000 feet altitude with a circular error of 40 yards at a range of 50 miles. The missile was ground-guided to the target by a computer, which also furnished the burst command. The missile had a single solid-propellant sustainer motor and a solid-propellant booster of four NIKE AJAX Jato's.[50]

The sustainer motor ignited when the booster separated (which was 3 to 4 seconds after launch) and burned for about 30 seconds. After burnout, the missile coasted to intercept. Intercept time varied from 20 to 200 seconds, and the missile was controlled in flight by aerodynamic surfaces on the trailing edges of the four fins which extended along approximately four-fifths of the length of the missile.[50]

Atomic Demolition Munition (Mk 30 Mod 1 Warhead)

The Mk 30 Mod 1 Warhead was designed to fulfill the requirements for the application of the Mk 31 Warhead as an Atomic Demolition Munition. The principal requirements were set forth in the military characteristics dated

October 21, 1958.[60] Authorization to proceed with development was received from Albuquerque Operations Office April 15, 1959.[61]

Some attention had been given to the desirability of incorporating environmental sensing devices in the Mk 31 (see the Mod 2 description) and for a time it was felt that these devices should also be applied to the munition. However, November 12, 1959, the Military Liaison Committee decided that field conversion of Mk 31 Warheads to atomic demolition munition use would not be required. It thus became possible to apply the Mod 2 only to Mk 31 Warheads for missile use. However, a combination lock was required, to provide handling safety for the munition.[62]

Design release of the Mk 31 Mod 1 Atomic Demolition Munition was accomplished in June 1960 and early production in September 1960. In order to meet this date, a lock-secured cover was completely developed in a relatively short time scale. In addition, a thermal plug was incorporated in the boosting-gas-reservoir system which provided added safety in the event that the munition was subjected to a fire environment.[60]

The outside diameter of the Mk 31 Mod 1 was 29.01 inches, length 43.75 inches, and weight 925 pounds. Y1, Y2 and Y3 yields were provided. Report SC4507(WD), Final Evaluation Report of the Mk 31 Mod 1 Warhead,[60] was reviewed in coordination with the interested Services and accepted by Field Command December 7, 1961.[63] It was noted that the design met all requirements of the military characteristics except for a slightly less than desired reliability figure. The report was forwarded to the Division of Military Application February 19, 1962.[64]

Mk 30 Mod 2 Warhead

The advent of sealed-pit weapons and the emphasis on immediate operational readiness for air-defense devices had greatly accentuated the need for safety.[65] Protection was required, both against accidents during warhead testing and the deliberate actions of a saboteur or psychotic. Sandia accordingly conducted an investigation and, March 1959, proposed incorporation of a handling safety device in all Mk 31 Warheads.

This device was a velocimeter consisting of a cylinder having a piston with orifices, a pair of normally open operating contacts, and latching and reset features. A breakaway mass was held in place by a restraining spring and a small magnet, and could be separated by applying a force of 2.5 g's. The piston then operated, and the contacts closed and latched.

In April 1959, the Division of Military Application proposed that handling safety devices be added to all Mk 31 Warheads and, September 1959, the Military Liaison Committee requested such incorporation. After design work, Sandia suggested use of an inertial switch, and final approval to proceed with this change was released October 1961. Since production of Mk 31 Mod 0 Warheads was essentially complete at that time, it was decided to retrofit the Y2, Y3 and Y4 warheads in the field at the time their boosting-gas reservoirs were replaced. Y1 warheads would be retrofitted whenever the weapon had to be disassembled for any reason.

Complete engineering release for the Mk 31 Mod 2 Warhead was dated June 1962. Early production of the Y2, Y3 and Y4 inertial switch pack for retrofit was March 1963, and early production of the Y1 switch pack was August 1963. Report SC4782(WD), Final Development Report for the Mk 31 Mod 2 Warhead, was reviewed and approved by Field Command September 13, 1963,[66] and forwarded to the Division of Military Application November 22, 1963.[67]

(b)(1), (b)(3)

Different inertial switch packs, differing only in detail, were used in the two applications. In normal operation, the warhead could not become completely armed until it had experienced a specified flight environment for a certain minimum time.[68]

CROSSBOW Application

Some consideration was given to application of the Mk 31 Warhead to the CROSSBOW, an Air Force air-to-surface missile designed to destroy enemy ground

radar installations. The missile, designed and built by the Radioplane Company of Van Nuys, California, would be flown to the launch zone by B-47 or B-52 bomber. The operator in the bomber, after acquiring enemy radar signals, would lock the missile's guidance system on this target. The missile could be released as far as 250 nautical miles from the target and would home on the radar station, detonating on contact.[69]

Study of applicable warheads was started in September 1953 and it was initially decided that either XW-7 or XW-12 use would require relocation of the air induction system and a redesign of the warhead compartment, and that new fuel tanks would have to be provided. Subsequently, however, a more detailed study was conducted and concluded that the XW-7 Warhead could be used. A marriage program for the XW-7/CROSSBOW was approved by the Military September 23, 1954, and Atomic Energy Commission support solicited.

This participation was delayed but, July 11, 1955, the AEC agreed to provide certain fuzing components and consultant services, which were made available by the fall of 1955. Subsequently, use of the XW-31 Warhead was suggested and a feasibility study conducted.[70] The study report was dated November 1955 and recommended that the XW-31 Warhead be used, due to its higher nuclear efficiency and reduced need for support and surveillance, as compared to the XW-7.[71]

(b)(1), (b)(3)

However, difficulties with the missile led to cancella-
made [73]

Deuterium -- The hydrogen isotope of mass number 2.

Division of Military Application -- An AEC office that functions as liaison between the Military and weapons designers and producers.

(b)(1), (b)(3)

Field Command -- The local office of the Armed Forces Special Weapons Project (Defense Atomic Support Agency as it was later called), located on Sandia Base, Albuquerque, New Mexico.

Firing System -- The electrical system of the weapon that produces and applies a high-voltage current to the detonators.

Fuze -- A combination of the arming and firing devices of a weapon.

g -- Force equal to one unit gravity.

Gas Boosting -- The technique of increasing the yield of a nuclear device by introducing deuterium-tritium gas into the implosion process to increase the fission activity.

Guided Missile -- A missile that is directed to its target while in flight or motion, either by a preset self-reacting device within the missile or by radio command outside the missile.

Hardtack -- A nuclear series of 72 tests. Hardtack I was held at the Pacific Proving Grounds from April 28 to August 18, 1958. The decision to declare a moratorium on testing resulted in Hardtack II, held at the Nevada Test Site between September 12 and October 30, 1958.

High-Explosive Sphere -- The ball of high explosive that surrounds the nuclear assembly and is designed to produce the implosion effect when detonated.

(b)(1), (b)(3)

(b)(1), (b)(3)

Jamming -- The practice of defeating radar by providing spurious responses in enemy equipment. Jamming can be passive or active.

Jato -- Named for Jet-Assisted Take-Off. A jet device initially designed to assist heavily loaded aircraft to take off from short runways. Used as a boosting device in missile launching.

Joint Chiefs of Staff -- A group composed of the Chiefs of Staff of the Army, Navy and Air Force, to determine policy and develop joint strategic objectives of the Armed Forces.

Joint Committee on HONEST JOHN Warhead Installations -- A committee, with representatives from nuclear, warhead and missile designer, and the Military, established to guide the activities related to the HONEST JOHN Warhead.

Joint Committee on NIKE-B Warhead Installations -- A committee, with representatives from nuclear, warhead and missile designer, and the Military, established to guide the activities related to the NIKE-B Warhead.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Lenses -- As applied to nuclear weapons, lenses are elements of the high-explosive sphere, which are designed to produce an implosion. The lens charge is composed of high explosives of different burning rates and is so constructed and shaped as to change the explosion initiated by the detonators into an implosive force which converges smoothly on the nuclear materials.

Los Alamos Scientific Laboratory -- A nuclear design organization located at Los Alamos, New Mexico.

Mach -- A measure of speed. Mach 1.0 is the speed of sound, or 738 miles per hour at sea level.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

Nautical Mile -- A naval measurement of length. One nautical mile is equivalent to 6076.1033 feet, or the length of 1 minute of arc (1/21,600) of a great circle of the earth.

Neutron -- An uncharged particle of slightly greater mass than the proton.

Nuclear Insertion -- Insertion of the nuclear capsule when the weapon is ready to be armed for detonation. An atomic weapon with a retracted capsule is relatively safe, and will only produce a yield equivalent to the amount of high explosive in the weapon if the arming and fuzing sequence was initiated and went to completion.

(b)(3)

(b)(1), (b)(3)

Radar -- Named for Radio Detecting and Ranging. Radars emit a pulse of high-frequency energy and measure the time lapse from that transmission to receipt of a reflected electrical "echo" from an object. This time measurement determines the distance of the object from the transmitting antenna of the radar.

Redstone Arsenal -- An Air Force arsenal, responsible for design of large rockets.

Reservoir -- As used in this history, a container for deuterium-tritium boosting gas.

Retrofit -- To modify a weapon, i.e. "retroactively outfit" it with changed material.

Safing -- Putting a weapon in condition such that it cannot fire.

Santa Fe Operations Office -- The local office of the Atomic Energy Commission (AEC) concerned with the Sandia operations. Renamed Albuquerque Operations Office, April 2, 1956.

Sealed Pit -- A weapon in which all the nuclear components (except the boosting gas, when used) are permanently installed in place. Designed to eliminate the need for inflight nuclear insertion mechanisms.

Special Weapons Development Board -- A joint Sandia-Military board at Sandia Base to provide local guidance on weapons design.

Squib -- A device containing a small powder charge. When detonated, the resulting gas pressure closes a switch or performs a similar action. A light, quick-acting one-shot device.

Supersonic -- Any speed exceeding that of Mach 1.0, which is the speed of sound, or 738 miles per hour at sea level.

Teapot -- A less-than-full scale test series held at the Nevada Test Site. Series of 14 tests, starting February 18 and ending May 15, 1955.

Telemetry -- The transmission of signals from a moving or distant object.

Thermal Battery -- A battery whose electrolyte is in a solid state while inactive. To activate, heat is applied to this electrolyte, melting it and putting the battery into active output condition.

Thyratron -- A grid-controlled electron tube.

Ton (Yield) -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-ton yield is equivalent to the detonation effect of 2000 pounds of high explosive.

Transistor -- A nonvacuum electronic device having uses similar to the electron tube, whose control of current is accomplished by the conductive properties of a semiconducter such as germanium.

Tritium -- The hydrogen isotope of mass number 3.

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent uranium-238; the rest is uranium-235.

Warhead -- A weapon carried to the target by missile.

X-Unit -- A device used to provide high voltage to the weapon detonators.

Yield -- The measure of the effect of a nuclear detonation compared to the effect of an explosion of TNT.

The Chief of Naval Operations wrote to the Bureau of Ordnance September 15, 1955, noting that a laydown bomb family with the range of yields noted above might require two different nuclear designs. One would be the single-stage XW-34 and the other might be an adaptation of the Mk 28 thermonuclear bomb.[14]

The military characteristics for the XW-34/LULU depth bomb were approved by the Military Liaison Committee October 4, 1955.

(b)(1), (b)(3)

The length and weight of the weapon would be held to a minimum, and not exceed 26 inches and 300 pounds, respectively.

The power supply would be a thermal battery. Since incorporation of this type of cell in a sealed package was undesirable from the standpoints of safety and surveillance, the battery would be located outside the sealed package. The operational requirements dictated that the depth bomb be capable of remaining in a completely assembled and ready-for-use condition, without loss of reliability, for a period of at least 180 days or 1000 flight hours, whichever occurred first. The weapon would be able to withstand linear accelerations of -2000 g's and +100 g's along the longitudinal axis, an acceleration of 800 g's along any axis perpendicular to the longitudinal axis, and angular accelerations about the longitudinal axis of 300 radians per second per second.[15]

The Assistant Secretary of Defense wrote to the Atomic Energy Commission October 6 1955, requesting that LULU and HOTPOINT feasibility studies be combined.[16]

(b)(1), (b)(3)

The initial step in this project would be to develop a bomb with a weight not over 1500 pounds and having a time-delay feature to permit release from very low altitudes and allow safe escape of the delivery aircraft.[17]

The Special Weapons Development Board discussed the laydown program in a meeting October 26, 1955. The feasibility study would be completed by December 1956, and

impacts with such targets as aircraft runways. A feasibility study was started on this design, which became the Mk 34 weapon.

The Step II weapon would be capable of being delivered at low altitudes by low-angle pitch-off or over-the-shoulder tactics. Fuzing would be air burst with a contact cleanup option. There would be preflight selectability between timer and radar, and inflight choice between radar and contact options. The air-burst height would be such as to eliminate severe residual contamination.

(b)(1), (b)(3)

Delivery would be by Navy AD4 aircraft. This Step II weapon became the Mk 28 Mod 2 Bomb.

The Step III weapon was a long-term development combining the characteristics of Steps I and II, and it would depend on future design progress. The device would be capable of delivery at both low and high altitudes and at speeds over Mach 0.9.

(b)(1), (b)(3)

This design would provide the Services with a single weapon or weapon family having tactical fuzing capabilities of air burst, ground contact, and delayed laydown options. This design became the Mk 43 Bomb.[20]

(b)(1), (b)(3)

Sandia forwarded the product definition for the XW-34 to Santa Fe Operations Office February 13, 1956. It was anticipated that the design could be released in April 1957, with early production in the second quarter of calendar year 1958.

(b)(3)

(b)(3) The overall depth bomb would be 18 inches in maximum diameter and 96 inches long, and would weigh about 1200 pounds. The depth bomb would be capable of internal or external carriage and delivery from low altitudes. Both timer and hydrostatic pressure fuzes would be provided.

Sandia would be responsible for nonnuclear bomb components and any associated test and handling equipment. The Naval Ordnance Laboratory would be responsible for the LULU adaption kit, including pressure hull and fuzing and arming system. The high-explosive case would be an aluminum sphere consisting of two caps with a center seal, and would be enclosed by the pressure hull. The battery assembly would contain five permanently potted thermal cells connected in series with an output of 2500 volts. An arm/safe switch would incorporate a motor, low- and high-voltage switches, and requisite circuits and hardware, all enclosed in a metal container. This switch could be operated by the pilot of the carrying aircraft through application of aircraft power.[22]

By early 1956 work was in progress on several components to be used in the Xw-34 program. One was a low-voltage thermal battery, with the capability of firing a squib switch and matches in the high-voltage thermal batteries, and of pulsing the X-unit gap. A battery life of 100 seconds was desired, and it was believed that a 28-volt thermal cell being developed by the Naval Ordnance Laboratory would be suitable. Another component was a switch whose contacts were closed until a deceleration of at least 15 g's was experienced. Another set of contacts were closed until a deceleration over 20 g's was experienced.

A safe-separation timer with a fixed time of 17 seconds and a fuzing timer with a fixed time of 6.25 seconds were needed, and it was felt that pyrotechnic devices being developed by the Naval Ordnance Laboratory could be used. Since there was only limited space available for the fuzing system, each component would have to be as small as possible. The fuze would be potted to withstand the shock of water entry.[23]

(b)(1), (b)(3)

Revised military characteristics for the LULU depth bomb were released by the Military Liaison Committee March 27, 1956. These noted that the weapon was a small-diameter, lightweight atomic bomb to be used in attack of submarines by carrier-based aircraft. The immediate objective was a weapon with some delivery restrictions and available for operational deployment April 1, 1958. The ultimate objective was a weapon capable of unrestricted delivery, including an ability to be dropped into shallow bodies of water and operate satisfactorily.

The maximum speed for external carriage was 300 knots, and the maximum launch altitude was 600 feet.

(b)(1), (b)(3)

It was hoped that the weapon would maintain reliability for at least 1000 flight hours. This would include three patrols per day, each of 4-hour duration, for a period of 90 days. Each patrol would start with a catapulted takeoff and end with an arrested landing.[25]

Report SC3759(TR), Proposed Ordnance Characteristics of the XW-34 Warhead for the LULU Depth Bomb,[26] was discussed in the 100th meeting of the Special Weapons Development Board held April 25, 1956, and this report was subsequently forwarded to the Division of Military Application.

(b)(1), (b)(3)

If the weapon was dropped into shallow water, it would be detonated by timer.

The watertight pressure hull of the LULU could withstand 1000-pounds-per-square-inch water pressure. The hull was internally pressurized with a dry gas at 5 or 10 pounds per square inch, and any need for desiccant was thus eliminated. The afterbody was

an aluminum sheet-metal cone perforated for rapid flooding. Two pieces of handling equipment were required, a storage/shipping container and a handling sling. Two test sets were designed, one to monitor the electrical circuits and the other to detect leakage of deuterium-tritium gas.

(b)(1), (b)(3)

The X-unit held four capacitors, dual-probe gap, and two gap trigger transformers. The high-voltage battery package contained five thermal batteries, two battery squib transformers, two thermal fuses, five silicon diode nets and two monitor switches.

A battery monitoring device indicated whether the thermal batteries had been fired. Thermal fuses were mounted near the outside edge of the potting and would melt in the event of aircraft fire before the battery heat-powder matches could ignite. Silicon diodes were installed in parallel with each battery to allow by-passing of defective units.

Special safety provisions were furnished. A safing plug grounded the boosting system, high-voltage battery initiation squibs, and all low-voltage pins. The high-voltage battery pack was not installed until preflight operations were in progress. The inflight safing switch opened the high-voltage circuit and grounded the capacitor bank, and the switch remained in this position until just before bomb release. A hydrostat switch in the adaption kit blocked arming and firing signals until it closed at the proper water depth.

The Navy desired that the weapon be compatible with all carrier-based aircraft planned through 1960. Requirements were for launches from altitudes of 0 to 600 feet and at release speeds of 0 to 300 knots; and it was hoped that launches could be made at altitudes as high as 2000 feet and speeds up to 600 knots. In water of less than 20-foot depth, a launch altitude of 150 feet and speed of 150 knots were specified.

(b)(1), (b)(3)

It was felt that the best way in which to provide this weapon, which could be delivered from low altitudes and high speeds with good accuracy, was through modification of the LULU design.

Subsequently, the Assistant Secretary of Defense wrote to the Atomic Energy Commission, September 19, 1956, noting that the feasibility study of a tactical/lay-down weapon family had been completed.

(b)(1), (b)(3)

Thus, in order to satisfy urgent requirements, it was requested that the Atomic Energy Commission cooperate with the Navy in the development through production of the XW-34/HOTPOINT. This weapon would

utilize LULU depth-bomb components, modified to increase shock resistance, and the Navy was assigned cognizance of the Department of Defense portion of the work.[28] Albuquerque Operations Office subsequently established a tentative operational availability date of October 1958.[29]

(b)(1), (b)(3)

The LULU Coordinating Committee replied that there appeared to be two methods for accomplishing this result.

(b)(1), (b)(3)

A meeting was held December 4 1956 with personnel of the Applied Physics Laboratory of the University of Washington, to discuss possible atomic devices for an antisubmarine torpedo, the ASTOR. This torpedo was 19 inches in diameter and 20 feet long.

(b)(1), (b)(3)

Atomic devices that could be applied to the ASTOR included the XW-34, XW-40 and possibly XW-25.[33]

Sandia wrote to Albuquerque Operations Office April 8, 1957, noting that there might be some logistical advantage to be gained by applying XW-34 to ASTOR.[34] Subsequently, the Assistant Secretary of Defense, May 14, 1957, requested the Atomic Energy Commission to proceed with development engineering adaption of the XW-34 to ASTOR.[35] Since the ASTOR would only have to withstand 60-g shock, 3-g vibrational environment, and a temperature range from -65°F to +130°F, the XW-34 could be used without modification.[36]

Identification of Mk 101 Mod 0 Depth Bomb had meanwhile been assigned to LULU, and production nomenclature of Mk 34 Mod 0 to the warhead.[37,38] The Mk 34 design was released in May 1957, with the exception of external initiators and final-assembly tester.[39] These items were released by October 1957.

The HOTPOINT weapon was discussed in the June 20, 1957 meeting of the Special Weapons Development Board. Target approach could be made at minimum altitude, which made detection of carrying aircraft difficult. Since delivery and escape maneuvers placed minimum burden on the pilot, special flight skill and training were not needed, and aircraft safety was enhanced. Attacks could be made from any direction, since an identification point was not necessary, and target identification became more positive. There were, of course, some disadvantages. The surface burst of the weapon produced ground contamination, and the combination of low-altitude and high-speed flight consumed aircraft fuel at a high rate. However, the advantages far outweighed the disadvantages.

(b)(1), (b)(3)

The weapon would be 19 inches in diameter, 162 inches long, and weigh about 1400 pounds. The tail cone would be explosively jettisoned 1/4 second after release of the bomb from the carrying aircraft, and an extraction parachute deployed. Another 1/4 second later, the afterbody would be detached by detonation of explosive bolts and pulled away from the weapon by the extraction parachute, thus releasing the main parachute.

Since LULU had been designed to withstand axial deceleration of 2000 g's combined with lateral shocks of 800 g's, it was felt that a suitable laydown weapon could be

(b)(1), (b)(3)

It was felt that the HOTPOINT was a good interim weapon. There were practically no limitations on the low-altitude delivery capability of the system, and the weapon was demonstrably rugged. In one test, the main parachute failed when the bomb was dropped from an altitude of 67 feet and a speed of 510 knots. A bomb containing live high explosive struck the ground with an impact velocity of 650 feet per second and slammed 3500 feet down a concrete runway before stopping. The drop was a severe overtest of the entire system but only minimal damage resulted, and the unit would have fired successfully.[42]

Meanwhile, LULU testing had been proceeding. Drop tests were made to determine that the weapon would enter the water at low angles without ricocheting. In 25 drops, angles from 6 to 30 degrees were tested at weapon impact speeds of 300 to 550 feet per second. Satisfactory results were obtained, as well as those from several hundred air-gun tests on components and assemblies.[43]

A cookoff test was conducted, in which the weapon was subjected to a gasoline fire for a period of about 30 minutes. During this test, temperatures as high as 1650°F were recorded, and there was a low-order explosion of the weapon after more than 13 minutes of fire. Test results indicated that there would be ample time to take necessary action in the event of fire following an airplane crash.[44]

Water drops of inert LULU weapons were conducted with extremely satisfactory results.[45]

(b)(1), (b)(3)

(b)(1), (b)(3) The shock resistance of the weapon exceeded all expectations and no damage to fuzing or firing systems was recorded. Additional water drops were made, with the weapons being subjected to temperature and humidity preconditioning. In these tests, which used weapons progressively closer to full production status, equally satisfactory results were obtained.

(b)(1), (b)(3)

It was the opinion of the Committee that the LULU met or exceeded the military characteristics.

The capability for bomb release at altitudes of less than 50 feet had not been conclusively proven, as the tail of one test aircraft had been hit by the water splash of the bomb when released from this altitude, and testing at this height had been subsequently discontinued.

(b)(1), (b)(3)

These drops were highly successful.[49]

The Mk 34 Mod 0 Warhead was design-released for use in LULU July 28, 1958.[50] Report SC4155(TR), Final Evaluation of the Mk 34 Mod 0 Warhead (LULU Application),[51] was presented to the August 20, 1958 meeting of the Special Weapons Development Board. The device was designed primarily for application in the LULU depth bomb, but could also be used with the ASTOR and HOTPOINT weapons.[52]

Meanwhile HOTPOINT testing had been proceeding. Air-gun firings were made, using live high-explosive spheres and simulated nuclear assemblies in some cases, and simulated spheres and live nuclear assemblies in others. The target was a concrete slab, and impact velocities ranged from 180 to 250 feet per second and impact angles from 8 to 60 degrees. One aluminum battery housing was ruptured during tumbling of the bomb after impact, and this material was changed to steel. An external initiator was included in the most severe test in the series and resulted in a cracked electronic tube and a slow leak, but the weapon probably would have functioned at the time of impact.[53]

Production authorization for the Mk 34/ASTOR was issued in March 1959, and an operational date of October 1960 was established. Since the ASTOR environment was much less severe than that of LULU and HOTPOINT, only a few tests were required to prove compatibility.[60] These included environmental tests of the torpedo compartment containing the Mk 34 and electrical tests of the system. A series of four fuzing and firing runs of the complete torpedo and Mk 34 were successfully conducted in mid-1959.

Report SC4750(WD), Final Evaluation of the Mk 34 (Mods 2, 3 and 4) Warhead to the Mk 45 (Mods 0 and 1) Torpedo (ASTOR), was published in June 1963. This report noted that at the time of development authorization, the torpedo was scheduled to be operational in the spring of 1960. Due to budget restrictions, the operational date was delayed until late 1962. The first release of the warhead for use in the ASTOR was October 10, 1960, with the Mk 34 Mod 1 (see later paragraphs for Mod 1 description) Warhead. Later, the Mods 2, 3 and 4 were also released for ASTOR use, and eventually a decision was made to use only the Mods 3 and 4.[61]

(b)(1), (b)(3)

(b)(1), (b)(3)

The bleeder resistors were placed in the neutron generators.

It was later decided to install a shielded pullout cable and a filter pack in the electrical circuit to attenuate any induced currents. The bleeder resistor was changed to 15 ohms, and this change constituted the Mk 34 Mod 3. A still further change, this time back to the 30-ohm bleeder resistors, resulted in the Mk 34 Mod 4 Weapon.[65]

Depth Bomb -- An explosive charge that detonates after sinking to a prescribed depth in water.

Detonators -- Explosive devices which, when initiated by the X-unit, ignite the lens charges of the high-explosive sphere.

Deuterium -- The hydrogen isotope of mass number 2.

Division of Military Application -- An AEC office that functions as liaison between the Military and weapons designers and producers.

Drogue Parachute -- A parachute that slows the rate of fall of a bomb.

Explosive Bolt -- A bolt containing a small charge of explosive. When detonated, the bolt fractures.

(b)(1), (b)(3)

Firing System -- The electrical system of the weapon that produces and applies a high-voltage current to the detonators.

Fuzing System -- The system that arms the weapon at the appropriate time and provides a firing signal to the firing system at the selected burst height.

g -- Force equal to one unit gravity.

Gap Switching -- An air gap normally prevents passage of electrical current. When this gap is ionized, it will act as a conductor.

Gas Boosting -- The technique of increasing the yield of a nuclear device by introducing deuterium-tritium gas into the implosion process to increase fission activity.

Gun-Type Design -- An atomic weapon based on the principle that a supercritical mass of nuclear material can be created by bringing together two subcritical masses of such material.

High-Explosive Sphere -- The ball of high explosive that surrounds the nuclear ~~primary~~ and is designed to produce the implosion effect when detonated.
fuzt and capsule

Hydrostat -- A pressure switch which closes at a prescribed water depth.

Implosion -- The effect created when a sphere of high explosive is detonated on it exterior surface. If suitable lens charges are provided to invert the explosion, the force of the shock wave is directed largely toward the center of the sphere.

Initiator -- A source of neutrons.

Joint Chiefs of Staff -- A group composed of the Chiefs of Staff of the Army, Navy and Air Force to determine policy and develop joint strategic objectives of the Armed Forces.

Joint Task Force -- A military group established to test the stockpile-to-target sequence of a weapon.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Knot -- A naval unit of speed, equivalent to 1 nautical mile or 6076 feet per hour.

Laydown Device -- A bomb capable of being dropped on a relatively hard target or surface and surviving in a condition to later detonate.

Lenses -- As applied to nuclear weapons, lenses are elements of the high-explosive sphere, which are designed to produce an implosion. The lens charge is composed of high explosives of different burning rates and is so constructed and shaped as to change the explosion initiated by the detonators into an implosive force which converges smoothly on the nuclear materials.

Los Alamos Scientific Laboratory -- A nuclear design organization located at Los Alamos, New Mexico.

Mach -- A measure of speed. Mach 1.0 is the speed of sound, or 738 miles per hour at sea level.

Matches -- As used in this history, matches are small charges of flammable material that are ignited by an electric spark. The flammable material heats up the solid electrolyte in the thermal battery, and places the battery in operating condition.

Megaton -- A measure of yield of a large weapon. One megaton is the equivalent of 1,000,000 tons of high explosive.

Microsecond -- One millionth of a second.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense Committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

(b)(1), (b)(3)

(b)(1), (b)(3)

One-Point Safety Test -- A test in which the high-explosive sphere is detonated at one detonator or point. If the device is one-point safe, no nuclear yield is produced.

Operation Plumbbob -- See Plumbbob.

Operation Redwing -- See Redwing.

Operation Teapot -- See Teapot.

Operation Wigwam -- See Wigwam.

(b)(1), (b)(3)

Radar -- Named for Radio Detecting and Ranging. Radars emit a pulse of high-frequency energy and measure the time lapse from that transmission to receipt of a reflected electrical "echo" from an object. This time measurement determines the distance of the object from the transmitting antenna of the radar.

Radar Option -- The option of detonating the weapon by radar, which can be set to trigger the weapon at a given height above the terrain.

Redwing -- A full-scale nuclear series of 17 tests held at the Pacific Proving Grounds from May 4 to July 21, 1956.

Reservoir -- As used in this history, a container for deuterium-tritium boosting gas.

Ring Lenses -- High explosive lenses formed in the shape of a ring to occupy less radial space.

Rotochute -- A device to slow down the rate of descent of a free-fall weapon. Consists of counterrotating propeller blades which absorb energy.

Santa Fe Operations Office -- The local office of the Atomic Energy Commission (AEC) concerned with Sandia operations.

Sealed Pit -- A weapon in which all the nuclear components (except the boosting gas, when used) are permanently installed in place. Designed to eliminate the need for inflight nuclear insertion mechanisms.

Services -- The Department of Defense.

Sonar -- A system for locating objects by echo reflection of sound waves from an object.

Special Weapons Development Board -- A joint Sandia-Military board at Sandia Base to provide local guidance on weapons design.

Squib -- A device containing a small powder charge. When detonated, the resulting gas pressure closes a switch or performs a similar action. A light, quick-acting, one-shot device.

Tactical -- Use of a weapon against troops or concentrations of war materiel.

Teapot -- A less-than-full-scale test series held at the Nevada Test Site. Series of 14 tests, starting February 18 and ending May 15, 1955.

Thermal Battery -- A battery whose electrolyte is in a solid state while inactive. To activate, heat is applied to this electrolyte, melting it and putting the battery into active output condition.

Tritium -- The hydrogen isotope of mass number 3.

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent uranium-238; the rest is uranium-235.

(b)(3)

X-Unit -- A device used to provide high voltage to the weapon detonators.

Timetable of XW-35 Events

1/7/52 — Military Liaison Committee requests Division of Military Application to make a feasibility study of a warhead for the ATLAS intercontinental ballistic missile.

(b)(1), (b)(3)

10/20/54 — Division of Military Application requests Los Alamos Scientific Laboratory, University of California Radiation Laboratory, and Sandia to study a suitable warhead design for ATLAS.

1/27/55 — Air Materiel Command requests Sandia to submit proposal for ballistic-missile warhead fuze.

3/1/55 — Sandia proposes two-phase approach to fuze design.

5/3/55 — Air Research and Development Command requests Sandia to proceed with fuze design.

7/55 — Authorization issued for feasibility study of thermonuclear warhead for an intercontinental ballistic missile.

9/9/55 — Sandia notifies Santa Fe Operations Office that the XW-35 Warhead can be produced by the fall of 1959.

11/29/55 — Sandia forwards ATLAS fuze proposal to Air Research and Development Command.

2/28/56 — Military Liaison Committee releases set of military characteristics for a warhead compatible with ATLAS, THOR and JUPITER missiles.

3/1/56 — Military Liaison Committee requests development of above warhead.

(b)(1), (b)(3)

7/18/56 — Albuquerque Operations Office authorizes production of XW-35 for ATLAS, TITAN, THOR and JUPITER missiles.

12/6/56 — Air Research and Development Command requests increase in yield of XW-35.

studies of a suitable warhead for the ATLAS, which had the most severe environment.

(b)(1), (b)(3)

The ATLAS missile had a maximum diameter of 10 feet, length of 75 feet, and blastoff weight of 243,300 pounds. Its booster engines possessed a total thrust of 300,000 pounds, and its sustainer engine a thrust of 60,000 pounds. The TITAN had a maximum diameter of 10 feet, length of 90 feet, and weighed 222,400 pounds. It had the same booster and sustainer engine thrusts. The THOR had a diameter of 8 feet, length of 62-1/2 feet, and gross weight of 110,400 pounds. It had one main engine with a thrust of 150,000 pounds. The JUPITER had a diameter of 8-3/4 feet, length of 58 feet, weight of 105,000 pounds, and the same thrust as the THOR.[5]

Air Materiel Command wrote to Sandia January 27, 1955, referring to Sandia's background in fuzing-system design, and requesting a fuze proposal for a ballistic-missile warhead.[6] Sandia replied March 1, 1955, suggesting a two-phase approach. Phase I would be a study of fuzing techniques and characteristics for a ballistic-missile environment, and Phase II would be development of a specific fuze.[7] Subsequently, Sandia was requested to design a fuze for the ATLAS. This would detonate the warhead at or near the surface of the target, to produce high contamination.[8]

(b)(1), (b)(3)

Accordingly, in July 1955, authorization was issued to study the feasibility of developing a thermonuclear warhead for an intercontinental ballistic missile. Due to the program urgency and the desire for the highest yield possible in a given weight, both Los Alamos and the Radiation Laboratory were requested to participate.

Sandia notified Santa Fe Operations Office September 9, 1955 that warhead designs could be firmed up by late 1957, with flight tests starting in early 1958.

SECRET

RESTRICTED DATA

Subsequently, the military characteristics for the Army's JUPITER warhead were approved by the Military Liaison Committee.

(b)(3)

Maximum yield and minimum weight were desired.[16]

The Division of Military Application was notified June 8, 1956 that early ATLAS and THOR missiles would be compatible with the same nose cone and warhead combination, and it was felt that this assembly could be applied to the TITAN. There was some question that any warhead optimized for the fairly blunt, thick nose being developed for ATLAS and THOR would also be best for the light glass ceramic nose cone of the JUPITER, even assuming that physical size and shape were identical. It was felt that full-scale tests might be required before any clear answer became evident.[17]

(b)(1), (b)(3)

The warhead would be carried by ATLAS,

RESTRICTED DATA

SECRET

TITAN and THOR missiles, and also the JUPITER, if this was possible without compromising the other designs.[19]

(b)(1), (b)(3)

This would provide a warhead for the ATLAS, THOR and JUPITER by their operational dates, and a warhead for TITAN well before its ready date. The University of California Radiation Laboratory would develop the XW-38, a higher yield and heavier warhead, for a later operational date.[20]

A composite warhead configuration was evolved to allow use of either the 20-inch-diameter XW-35 or the larger XW-38 with a common mounting flange. In the ATLAS and THOR nose cones, arming and fuzing components and attitude-control mechanism would be mounted in the annular space around the warhead. In the TITAN nose cone, the warhead would be mounted close to the front face, and this might involve heating problems. It would also have to be determined that weapon detonation would occur prior to nose deformation in contact bursts.[3]

The ATLAS, THOR and TITAN nose cones used copper heat sinks to distribute the heat throughout the nose-cone metal, which was expected to attain a temperature of about 1700°F. The JUPITER nose cone would be coated with a layer of fiberglass which would partially burn off during re-entry. This would physically remove heated material and it was hoped that the insulating properties of the fiberglass would help to keep the warhead compartment cool.[3]

Since it was felt that an antiballistic missile system might be in operation by 1960, the scheduled operational date for most of the missiles, it was desired that the warhead be made radiation-insensitive. This precluded use of transistors, diodes and similar devices. The warhead would be sealed and require a minimum of field testing. Monitoring would be accomplished through nose cone and missile consoles.[3]

The entire firing system would be potted, for adaptability to reduced pressures at high altitudes. The system would require three arming signals and either

October 1958. The warhead would be contained inside the nose cone, which would separate from the rest of the missile about 5 minutes after launch and then proceed along a ballistic trajectory to the impact point. Fuzing operations would occur upon re-entry into the atmosphere.[24]

The Assistant Secretary of Defense wrote to the Atomic Energy Commission March 29, 1957, noting that it was important that the ATLAS warhead yield be as large as possible within the prescribed weight limitations.

(b)(1), (b)(3)

The October 1958 operational availability date was to be retained at all costs.[25]

Report SC3995(TR), Proposed Ordnance Characteristics of the XW-35 Warhead, was discussed in the April 24, 1957 meeting of the Special Weapons Development Board.[26] The report proposed that a two-phase program be followed to provide a 20-inch version of the XW-35 for early operational capability and a higher yield version at a later date.[5] With the understanding that the XW-35 Mod 0 would be provided for initial use, the report was approved and forwarded to the Division of Military Application July 11, 1957.[27]

(b)(1), (b)(3)

the components.

(b)(3)

The main case and aft section would be sealed and pressurized to provide environmental protection during storage and operation. The firing system would be tested and certified at time of manufacture, and the warhead would require only continuity and pressure testing in the field or stockpile. There would be no field replacement of components and no need to break the warhead seal while the weapon was in military custody. The warhead would be provided with desiccant at the time of assembly to assure a low moisture content.

(b)(3)

Some suggestions had previously been made that emergency-capability warheads be provided. Thus, November 8, 1956, the Division of Military Application notified Albuquerque Operations Office that, as a result of a series of successful JUPITER tests, the Army was considering acceleration of this missile program.[31] Some attention was subsequently given to use of either XW-28 or XW-35.[32]

The same request was made, February 19, 1957, on behalf of the THOR.[33] Later, in August 1957, the JUPITER warhead emergency-capability program was cancelled.[34] However, December 2, 1957, the Military Liaison Committee noted that the Department of Defense was again accelerating the intermediate-range ballistic missile program. Both THOR and JUPITER squadrons, each requiring 15 missiles, would be operational by late 1958.

(b)(3)

In May 1958 it was decided that emergency-capability warheads for intermediate-range ballistic missiles would be supplied by XW-49 Warheads, which were

XW-28-Y1's modified to suit size and weight requirements. The emergency-capability units for the intercontinental ballistic missiles would be hand-built models of the XW-35-X1 and would be available by April 1959.[36]

Sandia wrote to the Division of Military Application May 5, 1958, nothing that considerable concern had been expressed over the safety of sealed-pit warheads.

(b)(3), (b)(1)

It had been suggested that an environmental sensing device be incorporated in the warhead electrical system to prevent detonation by any chance application of the sequence of electrical input signals. Study was being made of a single device that could be used with both missiles and bombs. The nose-cone re-entry deceleration formed a unique and common environment experienced prior to weapon detonation, and it was proposed that this deceleration pulse be used to close an inertial switch.

In the XW-35-X1 system, assembly of two such switches would be cross-connected and potted into a firing-set package. Production tests through warhead acceptance level would be accomplished by actuating the inertial switches on a centrifuge that would duplicate the re-entry environment, and electrical resets would be provided to return the switches to the safe position.[37]

(b)(1), (b)(3)

Pit -- The hollow metal sphere at the center of an implosion bomb which receives the nuclear capsule when it is inserted.

Plumbbob -- A less-than-full-scale test series conducted at the Nevada Test Site. Series of 29 tests, starting May 28 and ending October 7, 1957.

Potting -- A means for improving the shock resistance of any item by embedding it in a plastic compound.

Primary -- A fission bomb that acts as the source of emergy to start the secondary, or thermonuclear, reaction of a two-stage bomb.

Proton -- The nucleus of the atom of the light isotope of hydrogen. It has a unit positive charge of electricity.

Redwing -- A full-scale test series held at the Pacific Proving Grounds. Series of 17 tests, starting May 4 and ending July 21, 1956.

Re-entry Shock -- The shock produced when a missile re-enters the earth's atmosphere.

(b)(1), (b)(3)

Timetable of Mk 38 Events

(b)(1), (b)(3)

7/55 Study shows that design is feasible. Authorization issued to Los Alamos Scientific Laboratory and University of California Radiation Laboratory to proceed with parallel designs.

1/19/56 Nomenclature of XW-38 assigned to the Radiation Laboratory design.

3/56 Design expanded to include the TITAN intercontinental ballistic missile and the THOR and JUPITER intermediate-range ballistic missiles.

(b)(1), (b)(3)

7/18/56 Full-scale development of XW-38 Warhead authorized by Albuquerque Operations Office.

11/26/56 Division of Military Application changes design of XW-38 to a 3000-pound warhead, to be provided on a low-priority basis as a follow-on to the Los Alamos XW-35.

5/27/57 Assistant Secretary of Defense requests study of high-yield warhead for carriage by intercontinental ballistic missiles.

(b)(1), (b)(3)

5/7/58 Assistant Secretary of Defense requests feasibility study of high-yield warhead for ATLAS and TITAN.

(b)(1), (b)(3)

(b)(1), (b)(3)

3/11/59	Designation of XW-35-X1 assigned to high-yield XW-38 Warhead.
5/13/59	Amendment to the military characteristics deletes the requirement for compatibility of the XW-38-X1 with the THOR and JUPITER missiles.
11/59	Production authorization for XW-38-X1 issued.

(b)(1), (b)(3)

5/61	First unit of Mk 38 Warhead produced.
8/18/61	Report SC4825(WD), Mk 38 Mod 0 Status at Design Release, forwarded to the Division of Military Application.
6/63	Report SC4825(WD), Final Development Report for the Mk 38 Mod 0 Warhead, forwarded to the Division of Military Application.
Mid-1965	Mk 38 Warheads retired.

(b)(1), (b)(3)

The Assistant Secretary of Defense wrote to the Atomic Energy Commission, May 7, 1958, noting that the Joint Chiefs of Staff had approved an operational requirement for a high-yield warhead to be carried by intercontinental ballistic missiles. This weapon was to attack targets that required heavier payloads than the XW-35. The warhead would be designed for the ATLAS and TITAN, and it was hoped that it would be compatible with intermediate-range ballistic missiles. The warhead could weigh as much as 3500 pounds, have maximum yield for this weight, and was operationally desired by 1962.[13]

(b)(1), (b)(3)

The fuzing and firing components, ~~parachute and afterbody~~ would be contained in a cylindrical space 34 inches in diameter and 24 inches long.

(b)(3)

(b)(1), (b)(3)

Thus, the Department of Defense had authorized the development of such a weapon for application to the ATLAS, TITAN, THOR and JUPITER missiles. The warhead would be operationally available in mid-1961, and the Air Force was designated

cognizant agent for the Department of Defense portion of the program, with normal Armed Forces Special Weapons Project participation.[15]

A set of military characteristics was approved by the Military Liaison Committee January 20, 1959.[16]

(b)(1), (b)(3)

The warhead would be capable of becoming electrically armed within 5 seconds of receipt of the arming signal and remaining in this condition for at least 90 seconds, and would fire upon receipt of either air-burst or contact-burst signals. If, when armed, electrical energy was stored in the warhead awaiting the firing signal, a device would be incorporated to safely dissipate the electrical energy in the shortest time possible, not to exceed 10 minutes and not to interfere with the normal arming-firing sequence.

The warhead would not contain any primary source of energy. No final assembly procedures would be necessary after delivery of the warhead to the Military. Assembly of warhead to missile re-entry body would be as simple, quick and safe as possible, and require a minimum amount of specialized equipment and personnel.

At least one arming device, which would also serve as a safety device, was required to sense the unique environment of the missile after launch and before warhead operation. This device would be installed in a manner to minimize the possibility of nuclear detonation through sabotage. The design priorities emphasized safety from nuclear disaster to friendly installations, weapon reliability, operational simplicity, and ease of maintenance.[17]

(b)(1), (b)(3)

Sandia would have full responsibility for warhead design, except for nuclear materials and components.[18] A designation of XW-38-X1 was assigned to the program to distinguish it from the initial aims of the XW-38 project.[19]

(b)(1), (b)(3)

(b)(3) A production date of May 1961 would be required to meet the June 1961 operational availability date. These dates would require expediting the program to the utmost, and no delays could be tolerated in the missile flight-test program.

The Department of Defense agency responsible for the missile systems was the Air Force Ballistic Missile Division. Systems contractor for the Military was the Space Technology Laboratory, Inglewood, California. The Research and Advanced Development Division of Avco Manufacturing Corporation, Wilmington, Massachusetts, was the subcontractor for re-entry vehicle design and development. Avco would also provide arming and fuzing system design.

Warhead responsibility was divided between Lawrence Radiation Laboratory and Sandia's Livermore Laboratory. Lawrence was responsible for the nuclear functioning of the warhead and the design and production specifications of all nuclear components and materials. Sandia had responsibility for the design and production specifications of the remaining warhead components and materials.

Flight tests aboard TITAN were scheduled to start in March 1960, and a total of 16 flights were required to obtain necessary warhead environmental and systems operational data. A minimum of three successful warhead flight tests on the ATLAS missile were desired. Design release of the warhead was scheduled for August 1960.

There were three basic firing systems under consideration. One included explosive ferroelectric external initiators, an explosive ferromagnetic X-unit, and acceleration-sensing handling-safety devices. Another proposal featured an electronic external initiator, capacitor-type X-unit, chopper-converter system, trigger circuit, and acceleration-sensing handling safety devices. The third scheme had a Jonah initiation system, explosive ferromagnetic X-unit, and acceleration-sensing handling safety devices. The warhead would be sealed and require only continuity monitoring in stockpile or field.

The ATLAS was a 1-1/2-stage intercontinental ballistic missile 10 feet in diameter and 80 feet long. It was classed as a 1-1/2-stage missile because the two booster engines drew their fuel from the main missile tanks; the engines separated at the

end of the boost phase, but the tanks remained with the missile to supply fuel for the sustainer engine. The ATLAS weighed 269,000 pounds at takeoff, of which about 252,000 pounds was liquid oxygen and fuel for the rocket motors. The maximum range of the ATLAS was in excess of 5500 nautical miles, and it attained a speed of 23,500 feet per second (16,000 miles per hour). The booster engines each developed 165,000 pounds of thrust, and the sustainer engine 67,000 pounds. Final position and velocity adjustments for the missile were made by two small vernier rockets. After these vernier rockets stopped firing, the re-entry vehicle separated from the missile and followed a ballistic trajectory to the target.

The TITAN was a 2-stage intercontinental ballistic missile with a maximum range in excess of 5500 nautical miles. It was 10 feet in diameter, 97 feet long, and weighed 221,000 pounds at takeoff, of which about 200,000 pounds was liquid oxygen and fuel. The first-stage booster, which developed 300,000 pounds of thrust, separated from the rest of the missile at booster-engine cutoff, carrying with it all associated tankage, plumbing and controls. The second stage, or sustainer, then fired, developing 80,000 pounds of thrust. At sustainer-engine cutoff, vernier rockets made a final velocity correction. The re-entry vehicle then separated from the missile and followed a ballistic path to the target.

(b)(1), (b)(3)

(b)(1), (b)(3)

An amendment to the military characteristics was approved by the Military Liaison Committee May 13, 1959. This amendment deleted the requirement for compatibility of the XW-38-X1 Warhead with the THOR and JUPITER intermediate range ballistic missiles.[2]

Sandia wrote to Albuquerque Operations Office September 29, 1959, recommending that XW-38-X1 production units be identified as Mk 38 Mod 0 Warheads. Since advance ordering information was being provided to meet the accelerated production schedule, it was felt that production nomenclature should be assigned, and this suggestion was subsequently accepted.[22,23] Production authorization for the warhead was issued in November 1959.

(b)(1), (b)(3)

The Division of Military Application, in a teletype of June 10, 1960, suggested that the XW-38-X1 be assigned a high priority, in an effort to retain the early production date of May 1961.[25] Sandia and Lawrence issued a joint reply, June 30, 1960, stating that the program status did not warrant release of material for operational use.[26] Despite this, however, the project was authorized use of extra funds, and calculated risks in early assembly were taken.

(b)(1), (b)(3)

Early production units of the Mk 38 Warhead began to flow from the assembly lines in May 1961.

The ablative heat shield was constructed of fiberglass covered with oblique tape-wound fibrous quartz.

An integrating inertial switch was provided, with two sets of normally open contacts, which interrupted input lines from the adaption kit to the warhead arming components. This switch prevented arming until the warhead experienced an acceleration environment of powered flight. The switch contacts closed when the warhead had undergone a minimum acceleration of 3.5 g's and an acceleration-time product of at least 15 g-seconds. The switch would not operate under an acceleration of 2 g's or less, regardless of how long this acceleration was applied. Accelerations greater than 10 g's were clipped, ensuring that momentary applications of very high accelerations would not close the switch.

(b)(1), (b)(3)

(b)(1), (b)(3)

The firing set contained a dual-channel chopper-converter, a single-channel capacitor X-unit, and a tack switch. This assembly received 28 volts direct current from the adaption kit and converted this to alternating current, which was transformed into two higher voltages, rectified separately and supplied to the X-unit

When the missile attained the position and velocity necessary for the re-entry vehicle to reach its target, a guidance prearm signal from the missile passed through a lockout switch.

(b)(1), (b)(3)

A separation signal from the missile then passed through the lockout switch and operated the missile/re-entry vehicle separation mechanism. The re-entry vehicle separated from the missile and followed a ballistic path to the target.

(b)(1), (b)(3)

When the re-entry vehicle entered the atmosphere, it righted itself and started to decelerate. This deceleration activated the arming-firing battery in the adaption kit. When this battery came up to voltage, it supplied power through environmental sensing devices to the chopper-converter motors.

(b)(1), (b)(3)

If air burst had been selected, the air-burst switch operated at the selected altitude, sending a firing signal through the air-ground relay to the tack switch. This switch transferred energy from the X-unit capacitor to the warhead detonators and triggered the neutron generators. If ground burst had been selected, or if the air-burst switch failed, impact detectors in the nose of the re-entry vehicle were actuated by the ground impact. These detectors triggered a signal that fired the tack switch.

The design-release report was presented to the Design Review and Acceptance Group of Field Command. It was noted that the design met all requirements of the approved military characteristics, with the following exceptions: The warhead length had been increased to 82.45 inches, but this was at the request of the using Service for convenience in adapting the warhead to the re-entry vehicle, and was acceptable.

An increase in weight to 3080 pounds was acceptable in view of a mutually agreed-upon upper limit of 3130 pounds.

(b)(1), (b)(3)

The overall design was thus felt to be acceptable to the Department of Defense, and Report SC4825(WD) was forwarded to the Division of Military Application August 18, 1961.[28]

Report SC4842(WD), Final Development Report for the Mk 38 Mod 0 Warhead, was released in June 1963.[29] Flight testing had been initially delayed to incorporate components fully representative of War Reserve items and again postponed due to nonavailability of missiles. Thus the flight tests, which had been originally scheduled for completion in early 1961, were not finished until December 1962.

(b)(1), (b)(3)

Albuquerque Operations Office issued notice December 11, 1964, that the Division of Military Application had decided to retire the Mk 38 Warhead by mid-1965. Sandia was requested to cancel any further design changes.[30]

RESTRICTED DATA

Kilogram -- A metric weight approximating 2.2 pounds.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Lawrence Radiation Laboratory -- A change of name for the University of California Radiation Laboratory (which see), effective October 1958.

Lenses -- As applied to nuclear weapons, lenses are elements of the high-explosive sphere, which are designed to produce an implosion. The lens charge is composed of high explosives of different burning rates and is so constructed and shaped as to change the explosion initiated by the detonators into an implosive force which converges smoothly on the nuclear materials.

Los Alamos Scientific Laboratory -- A nuclear design organization located at Los Alamos, New Mexico.

Megaton -- A measure of yield of a large weapon. One megaton is the equivalent of 1,000,000 tons of high explosive.

Microsecond -- One millionth of a second.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

(b)(1), (b)(3)

Operation Hardtack -- See Hardtack.

Operation Plumbbob -- See Plumbbob.

Operation Redwing -- See Redwing.

AEC ATLANTA AUSTRALIA

Pit -- The hollow metal sphere at the center of an implosion bomb which receives the nuclear capsule when it is inserted.

Plumbbob -- A less-than-full-scale test series held at the Nevada Test Site. Series of 29 tests, starting May 28 and ending October 7, 1957.

Primary -- A fission bomb that acts as the source of energy to start the secondary or thermonuclear reaction of a two-stage device.

Proton -- The nucleus of the atom of the light isotope of hydrogen. It has a unit positive charge of electricity.

Redwing -- A full-scale nuclear series of 17 tests held at the Pacific Proving Grounds from May 4 to July 21, 1956.

Re-entry Vehicle -- That part of a ballistic missile that forms the nose of the missile, generally contains the warhead, and is detached from the missile during the trajectory to re-enter the earth's atmosphere and follow a ballistic trajectory toward the target.

Reservoir -- As used in this history, a container for deuterium-tritium boosting gas.

Santa Fe Operations Office -- The local office of the Atomic Energy Commission (AEC) concerned with Sandia operations.

Secondary -- The thermonuclear portion of a two-stage weapon.

Services -- The Department of Defense.

Squib -- A device containing a small powder charge. When detonated, the resulting gas pressure closes a switch or performs a similar action. A light, quick-acting, one-shot device.

Thermal Battery -- A battery whose electrolyte is in a solid state while inactive. To activate, heat is applied to this electrolyte, melting it and putting the battery into active output condition.

Thermonuclear -- Two-stage reaction, with a fission device exploding and starting a fusion reaction in light elements.

Ton (Yield) -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-ton yield is equivalent to the detonation effect of 2000 pounds of high explosive.

Tritium -- The hydrogen isotope of mass number 3.

Two-Stage -- Combination of fission and fusion action in a weapon.

University of California Radiation Laboratory -- A laboratory established at Livermore, California. Initially founded for work on the thermonuclear designs.

AUSTRALIA ATLANTA AEC

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent uranium-238; the rest is uranium-235.

Warhead -- A weapon carried to the target by missile.

X-Unit -- A device used to provide high voltage to the weapon detonators.

8/20/58 Sandia presents final evaluation of Mk 39 Mod 1 Bomb/Warhead to meeting of Special Weapons Development Board.

(b)(1), (b)(3)

Mk 39 Mod 2 Bomb

9/17/56 Field Command requests Sandia to study feasibility of a laydown Mk 39 Bomb.

11/18/57 Air Force notifies Division of Military Application that Strategic Air Command has urgent requirement for a low-altitude laydown Mk 39. Design named the Big Tail.

(b)(1), (b)(3)

When the bomb fell a sufficient distance, the pressure switch closed. When open, this switch isolated the low-voltage power supply from the coils of the high-voltage safing switch. When closed, power from the low-voltage battery pack operated the high-voltage safing switch, completing the circuit between the high-voltage power supply and the X-unit. At arming altitude, the arming baroswitch closed and connected the 28-volt power supply, through two fuses, to the primaries of two high-voltage thermal-battery ignition transformers. The pulse from the transformer secondaries activated the high-voltage power supply and the two fuses blew in approximately 100 milliseconds and removed this high current load from the low-voltage power supply. The high-voltage power supply charged the X-unit to 2500 volts and supplied this voltage to the trigger circuit.

At air-burst firing altitude, the baroswitch closed, connecting the 28-volt power supply, through two fuses, to saturable transformers in the trigger circuit. The two fuses blew in approximately 100 milliseconds and removed this high current load from the power supply. In the air-burst option, the saturable transformers passed the fire signal, firing the trigger circuit, X-unit, and the weapon. In the contact option, the saturable transformers blocked the fire signal, and the weapon was detonated by a signal from the contact fuzing system.[23]

The drop-test program for the bomb consisted of 28 drops, 8 of which were ballistic and 20 were fuzing and firing tests. These proved compatibility with the bomb, parachute system, and carriers. The fuzing and firing drops covered a wide range of speeds and altitudes, with about half the drops being free fall and the other half retarded.

had been proposed, including the Mks 7, 12 and 30, but it was felt that they were too heavy for their yield.[2]

However, as missile design became more firm, the Air Force Special Weapons Center notified Sandia, December 12, 1955, that the missile would become operationally available July 1, 1959. It was felt that the warhead compartment of the BOMARC would be able to carry an atomic device with a diameter of 18 inches, and that space should be available for X-unit, gas-boosting equipment, and external initiator.

(b)(1), (b)(3)

Sandia replied December 28, 1955, stating that a 17-inch-diameter warhead could be developed, which would have a weight less than 300 pounds and the desired yield, and be able to survive the BOMARC's launching boost and cruising speed.

(b)(1), (b)(3)

Another missile came under consideration January 26, 1956, when the Assistant Secretary of Defense wrote to the U. S. Atomic Energy Commission, noting that the Army was developing the LACROSSE missile and hoped to achieve an atomic capability.[5] The LACROSSE had a 20.5-inch-diameter body which was 19 feet long and weighed 2350 pounds at launch. It had a wingspan of 9 feet, two main swept-back wings, and a 4-fin tail. The initial launching boost, as well as flight power, was provided by a solid-fuel rocket which produced a missile speed of Mach 1.5.

The LACROSSE was a surface-to-surface missile designed for precision delivery against land targets under direct observation in close support situations. The missile was launched from a 2-1/2-ton Army truck located from 8,000 to 30,000 meters from the target (5 to 18.5 miles). The missile was launched in the general direction of the target and flew at altitudes between 5,000 and 13,000 feet above the launching point. It was acquired in flight by a jeep-transported forward guidance station and guided to the target by radio and optical techniques.

(b)(1), (b)(3)

A feasibility study of possible warheads for the LACROSSE missile was completed by Sandia and forwarded to Albuquerque Operations Office June 6, 1956.

(b)(1), (b)(3)

Both these warheads could be made available by April 1959.[11]

By mid-1956 the design of the XW-40 Warhead was taking shape. The warhead would be sealed and gas-boosted. The warhead electrical system was practically identical with the Mk 28 system, and used the same X-unit, removable high-voltage battery pack, dual external initiators, dual motor-operated arm/safe switches, gas-boosting mechanism, and dual cold-cathode thyratron trigger circuits.

(b)(3), (b)(1)

The warhead diameter would be slightly larger than desired, 17.9 inches, and the length would be 31.56 inches. It was expected that the weight could be held to 290 pounds. Only minor maintenance would be permitted in the field, since assembly or disassembly of the sealed warhead would require special tools. Positive safing during storage and handling was provided by removable batteries. The warhead would be pressurized with dry air or nitrogen.[13]

(b)(1), (b)(3)

(b)(1), (b)(3)

The Army's Picatinny Arsenal had advocated that interface problems on the XW-40/LACROSSE be handled by the concerned project officers, rather than through a special joint committee, as had been the custom for previous weapons. It was suggested that the participating agencies each appoint a representative; with Sandia being responsible for the warhead, the Army responsible for the rest of the missile-warhead system, and the Armed Forces Special Weapons Project responsible for the interests of other military services.[17] This proposal was adopted.[18]

A third missile program was introduced when the Assistant Secretary of Defense wrote to the Atomic Energy Commission, September 19, 1956, requesting cooperation with the Navy in the feasibility study of a nuclear warhead for the CORVUS missile.[19] The CORVUS was an antiship, air-launched missile designed to home-in on enemy radar installations. The CORVUS was scheduled to be operationally deployed for evaluation in mid-1960, with delivery to the Fleet in April 1961. The missile would be carried by AD4-, A3D-, and P6M-type aircraft, which would launch the missile from a maximum standoff range of about 170 nautical miles.[20]

A working group was established, and Sandia studied the physical fit of several nuclear warhead designs in the CORVUS.[21] There were some warheads that could be

modified for such installation, but none met all the requirements established by the Navy Bureau of Aeronautics.

(b)(1), (b)(3)

An XW-40/CORVUS could be provided which would meet most of the Navy requirements, but modification of warhead case and missile compartment would be necessary. It was felt that this redesign might delay the release date of the warhead, currently estimated as January 1958, and affect its application to the BOMARC and LACROSSE.[22]

Work had meanwhile been proceeding on the design of the XW-40 Warhead. The high-voltage battery package would contain five batteries connected in series, with a pair of silicon diodes shunted across each set of battery terminals to allow normal operation of the other four batteries, should one unit fail. Thermal fuses would be located in the ground line to isolate the battery output in the event of fire. Dual squib transformers would be provided to minimize power requirements and to provide increased reliability and reduced size. The high-voltage arm/safe switches would be motor-driven and reversible, thus affording positive control. These switches were inherently fire-safe and could not be inadvertently operated by electromagnetic radiation.

The gap switch of the XW-40 could be fired by either of two methods. One was by a low-impedance source, provided by the adaption kit, with signals derived from timers, impact switches, or barometric switches. The other was by a high-impedance source, such as supplied by radar, thyratrons or contact crystals. This required the design of a 4-probe gap and four pulse-type firing transformers; two for the low-impedance and two for the high-impedance signals.

The use of the warhead in the air-defense BOMARC made it mandatory that the warhead components have low sensitivity to nuclear radiation.

(b)(3)

(b)(3)

Components that were squib-initiated or explosively operated were also sensitive to electromagnetic radiation and discharges of static electricity.[6]

Sandia notified Albuquerque Operations Office, February 5, 1957, that no approved military characteristics had been received for the XW-40 Warhead. It was estimated that flight tests of the warhead in both the BOMARC and LACROSSE would start by May 1957, with 15 flights being required to provide necessary environmental and systems operational data. The first squadron of BOMARC and LACROSSE missiles would not become operational until mid-1959, although the warhead would undoubtedly be available by this time.[23]

The Division of Military Application wrote to Albuquerque Operations Office March 6, 1957, noting that the operational availability date of the XW-40 Warhead had apparently slipped from January to July 1959, and requesting an explanation of the delay.[24] Albuquerque Operations referred the request to Sandia, noting that, if at all possible, the earlier date should be maintained. It was felt that warhead availability should not be tied to the date on which a missile squadron became operational.[25]

Sandia replied, April 10, 1957, that the latest flight-test schedule dates meant that the six required systems tests of the XW-40 Warhead in the BOMARC and LACROSSE missiles would not be completed until some time after January 1958. It was felt that at least nine missile flights would be required to provide six successful tests. Thus, a design-release date of July 1958 for the warhead and an operational-availability date of mid-1959 appeared to be logical.

(b)(1), (b)(3)

(b)(1), (b)(3)

Picatinny Arsenal had requested Sandia to prepare a contract covering flight-test telemetering and use of Sandia's sled track for contact-fuze tests of the XW-40/LACROSSE program. This contract was submitted to Albuquerque Operations Office April 12, 1957, and subsequently put into effect.[27] It had been decided that interface problems of the XW-40/BOMARC program would also be handled on a project-officer basis.[28]

(b)(1), (b)(3)

Approved military characteristics for the XW-40 Warhead were released by the Military Liaison Committee June 18, 1957. Warhead applications included BOMARC and LACROSSE missiles, as well as other applications that might be authorized by the Department of Defense. The parameters of the warhead would be held to a practicable minimum and would not exceed a diameter of 17.4 inches, length of 31.7 inches, and a weight of 300 pounds.

(b)(1), (b)(3)

Preliminary investigation had indicated the feasibility of incorporating such high-yield warheads in the BOMARC missile, and a study was requested.[30]

(b)(1), (b)(3)

Either design could be made operationally available by January 1962 without interference with existing work.[31] The project was subsequently canceled April 22, 1958, as it was felt that the XW-47 Warhead then being designed for the POLARIS missile would better satisfy the requirements.[32]

Sandia presented Report SC4071(TR), Proposed Ordnance Characteristics for the XW-40 Warhead, to the August 21, 1957 meeting of the Special Weapons Development Board.[33]

(b)(1), (b)(3)

The Board accepted the report and it was subsequently forwarded to the Division of Military Application.[35]

(b)(1), (b)(3)

The Assistant Secretary of Defense wrote to the Atomic Energy Commission November 13, 1957, noting that a joint feasibility study for a nuclear warhead for the CORVUS missile had been completed. The study had concluded that the XW-40 Warhead could be applied to the missile without change, and it was requested that design of the project be instituted, in cooperation with the Navy.[36]

Meanwhile, it had been decided that the BOMARC adaption kit would be provided by the Air Force. This kit would contain an arming and fuzing system, external power supply, and most of the self-destruct system. The safing and arming device was a limited integrating accelerometer. The kit contained an arming program that sequenced the input signals to the warhead and fuze.

The warhead would normally be detonated by its primary fuze, an electronic influence device. A secondary predictor-computer-type fuze would receive information from a target seeker and provide backup if the target did not come within firing range of the primary fuze.

(b)(3)

Boeing Airplane Company was supplying the adaption kit, and the Diamond Ordnance Fuze Laboratory was developing the arming and fuzing system.[1]

Field Command noted that the failure probability of 1 to 130 for the self-destruct system was far short of the 1 to 10,000 required by the military characteristics.[37] Sandia replied, February 12, 1958, stating that the warhead design was well along when the approved military characteristics were released, and that any appreciable gain in reliability could only be achieved through the use of dual systems. This would lengthen the warhead by 3 inches, increase its weight by 5 pounds, and require 6 months' additional development time. Since both BOMARC and LACROSSE missiles used ~~in~~ a single-channel self-destruct system, it appeared that this signal derivation could not approach the reliability requested.[38]

The Division of Military Application sent a teletype to the Albuquerque Operations Office March 31, 1958. Recent information had indicated an activation date of October 1959 for the first LACROSSE squadron, and it therefore appeared that a warhead operational availability date of July 1959 would be suitable.[39]

(b)(1), (b)(3)

agency was the Navy Bureau of Aeronautics, with the Bureau of Ordnance assisting in problems of fuzing, arming, self-destruction and warhead-missile compatibility.[50]

The Mk 40 Warhead was released for use in the BOMARC and LACROSSE June 30, 1959, and early production of the warhead occurred September 1959. Report SC4189(TR), Status at Complete Design Release and a Final Engineering Evaluation of the XW-40 Warhead,[51] was presented to the October 21, 1959 meeting of the Special Weapons Development Board. The warhead was 17.9 inches in diameter, 31.5 inches in length, and weighed 304 pounds. (b)(1), (b)(3)

The Board accepted the report for forwarding to the Division of Military Application.[53]

(b)(1), (b)(3)

(b)(1), (b)(3)

Normally, such a change would have required a new Mod number of the warhead. However, since only a few items had been produced, it was felt that adequate control could be maintained by serial number until all the warheads had been properly retrofitted.[54]

At this time, a proposal was made to incorporate an environmental safing device to provide increased safety in handling the Mk 40 Warhead. This device would be operated by the acceleration experienced by the warhead in the boost phase of the missile flight, and the Services were requested to provide the appropriate longitudinal accelerations.[55]

Sandia wrote to Field Command March 28, 1960, discussing current progress in the self-destruct system.

(b)(1), (b)(3)

To satisfy the military characteristics, development work had been started on a dual-channel charging and triggering circuit, but it was evident that these improved units would not become available until a substantial number of the Mk 40 Warheads had entered stockpile.

(b)(1), (b)(3)

Transistor production difficulties had delayed the firing sets,

action link or arming-control device to be incorporated into the LACROSSE application for an additional measure of command control. This would have created the Mk 40 Mod 3.[67] Subsequently, Albuquerque Operations Office sent a teletype to Sandia April 10, 1963, stating that the Division of Military Application had ordered suspension of activity on the Mk 40 Mod 1 and Mod 3 for LACROSSE, applying both to the environmental sensing device and prescribed action link.[68] Eventually, a few Mod 1's were produced and stockpiled in August 1964, but they were withdrawn several months later.

Design work continued on the Mk 40 Mod 2 for the BOMARC application.[69] A ground compatibility test was held, which disclosed electrical feedback through missile wiring from one motor-driven arm/safe switch to the other when the motor speeds were sufficiently different. This feedback caused a cyclic condition that caused the switches in some warheads and missiles to run abnormally long before stopping at their proper positions. Due to a difference in wiring, this problem applied only to the XM-99A or early BOMARC design.[70]

Sandia studied the situation and reported, May 27, 1963, that modification of the Mk 40 Warhead did not appear to be warranted, as the switch cycling was not caused by any warhead defect. It was pointed out that peacetime nuclear safety was not lowered, and that the total effect of the cycling on warhead safety was minor. The condition was dependent on the missile's being launched, the warhead's being fully armed, a failure of the system to detonate the warhead, and a failure of the self-destruction system. It was noted that, if all these events occurred, and the arm/safe switch failed to return to safe for any reason, including cycling, some nuclear yield might be produced when the warhead impacted the ground. It was suggested that warheads in stockpile be tested and that defective units be replaced.[71]

Mk 40 Mod 2 retrofit kits were subsequently stockpiled in December 1963 for use with the BOMARC missile.

The Radiation Laboratory would have responsibility for nuclear components, and Sandia would be responsible for nonnuclear components. Project responsibility would rest with Sandia-Livermore, with Sandia-Albuquerque furnishing assistance on such items as nose fairing, afterbody, fins and fuzing system.

The weapon would have a diameter of 50 inches, warhead length of 120 inches and weight of 9300 pounds, and bomb length of 145 inches and weight of 10,000 pounds. The high-voltage power supply would be removable, but otherwise the entire weapon would be sealed, and the fuzing and firing system tested as a go/no-go assembly. Warhead fuzing would be provided by the missile contractor.

(b)(1), (b)(3)

Sandia wrote to the Air Force Special Weapons Center April 17, 1957, suggesting that a joint working group be formed to consider problems relating to the XW-41/NAVAHO.[16] A similar letter, dated April 22, 1957, requested the support of the 4925th Test Group (Atomic) in the bomb drop-test program. This program would prove out the fuzing and firing system and determine ballistic performance, and the series would consist of 42 drops, half of which would be parachute-retarded. Drops would start in November 1957, proceed at the rate of two or three per month, and be completed in early 1959. Releases would be made from B-47 and B-52 aircraft, flying at speeds of Mach 0.75 to 0.9 and at altitudes between 20,000 and 55,000 feet. About half the tests would be made over water and half over land, with the facilities of both Salton Sea Test Base and Tonopah Test Range being used.[17]

The Radiation Laboratory notified the Division of Military Application April 29, 1957 that there was a serious question concerning compatibility of the XW-41 Warhead in the NAVAHO warhead compartment.

(b)(1), (b)(3)

(b)(1), (b)(3)

The missile could be redesigned to provide more clearance between bulkheads and warhead, and it was proposed that the NAVAHO be made a desired, rather than a mandatory, carrier of the XW-41.[18]

On May 9, 1957, the Air Force Special Weapons Center requested Sandia to design a system for automatic deployment of the TX-41 parachute. By referring this design to Sandia, it became possible to include the retardation system within the sealed portion of the bomb. This provided better control of the parachute storage environment and extended the parachute repack interval.[19] Sandia subsequently designed a drogue-gun which, when fired, initiated the parachute deployment sequence.

The Assistant Secretary of Defense notified the Atomic Energy Commission May 27, 1957, that the Air Force had canceled the compatibility requirements for the XW-41 Warhead in the B-58 Pod application.

(b)(3)

The joint working group for the NAVAHO had been activated, but rumors had circulated that the missile would be canceled.[21] The Air Force Special Weapons Center notified Sandia June 5, 1957 that informal information indicated the program would be continued on an expedited basis, but not on the high priority it had enjoyed up to this point. Warhead flight testing would be delayed until mid-1960, with an operational date a year later.

(b)(3)

The Air Force Special Weapons Center notified Sandia November 25, 1958 that the Strategic Air Command had decided to always release the TX-41 from the B-47 and B-52 aircraft in the retarded condition. Thus, there was no requirement for an option-selector switch, and the bomb could be designed so that the parachute would always deploy upon bomb release.[48]

Sandia wrote to Field Command December 8, 1958, discussing the need for additional safing devices on the TX-41 Bomb. Sandia pointed out that the Air Force Nuclear Weapon Safety Group had reported that the TX-41 was completely acceptable from the standpoints of accidental or premature detonation, provided that the bomb was not released in an armed condition. However, during airborne alert missions, the human element was predominant, and safety during these periods would be controlled by the probability of an arming signal being inadvertently furnished.

Sandia noted that any improvement in overall safety would have to reduce the foregoing possibility. All the systems studied had involved the installation of additional arming control switches in the aircraft at a crew station remote from the aircraft monitor and control station. Another possibility would be to install an additional switch at the aircraft monitor station, such that both switches were in series for weapon arming and in parallel for weapon safing. The first design would cause a slippage in time scales or require weapon retrofit, increase weapon complexity, and introduce logistics and compatibility problems, and Sandia recommended the second system.[49]

Field Command notified Sandia January 9, 1959 that the Air Force Special Weapons Center had again changed the requirements, and now desired selective free fall or retarded capability of the TX-41 Bomb. Reinstatement of the option-selector switch was requested.[50]

Meanwhile, Sandia had made a study of the TX-41 weapon features that would impede or deny access to bomb arming circuits, and proposed certain changes to Field Command.[51] These modifications were accepted February 9, 1959, and included deletion of the need for removal of the battery.[52] This change decreased weapon handling and increased the resistance of the bomb to actions of saboteurs and psychotics. It was noted that the firing set was inert and would only respond

to external signals furnished in a definite order. Additionally, between low-voltage battery and firing set, there were three separate safing devices that had to be armed in order for power to reach the firing set.[53]

The Mk 41 Bomb was released for pilot production in April 1959.[54] Subsequently, full design release was authorized in September 1959, with the publication of Report SC4813(TR), Description and Status at Design Release of the TX-41 Bomb.[55] This report noted that the bomb was 50 inches in diameter, 148 inches long, and weighed 10,500 pounds. (b)(1), (b)(3)

The report was presented to the October 21, 1959 meeting of the Special Weapons Development Board and accepted.[56]

The Division of Military Application had requested that a formal study be made of the compatibility of the bomb with B-70 aircraft.[57] The Radiation Laboratory, now renamed the Lawrence Radiation Laboratory, reported in a teletype of October 16, 1959 that the B-70 would subject the Mk 41 to a severe heat environment that would damage the nuclear components. There appeared to be two possibilities; to design a bomb capable of withstanding the temperature, or provide bomb cooling or insulation. The first approach would require a close study before it could be determined whether a new nuclear test would be required. The second approach appeared immediately feasible, but the modification would have to be made by the Air Force and the aircraft contractor.[58]

Meanwhile, much work had been done on the development of the aerodynamic shape of the Mk 41. Initially, three different shapes were tested in the wind tunnel; one similar to the Mk 21, another the same as the Mk 27, and a finless shape. A large nose flat on each model provided adequate space for mounting the contact-fuze crystals. The first wind-tunnel tests showed that a nose flat greater than 0.577 of the body diameter would produce dynamic instability.

The finless shape was found to be unstable. A decision was then made to use the Mk 21 shape, since it provided more room for fuzing-and-firing components, and stability was increased by adding a spoiler band. The Air Force reported that a

The fuzing and firing system used baro arming and fuzing in the air-burst option, and baro arming and impact-crystal operation in the ground-burst option. The impact crystals provided backup for the air-burst mode. Before takeoff, the baroswitch was set to the desired air-burst altitude and the safing switch turned to STRIKE. Inflight selection of either air burst or ground burst caused the fuzing-system control selector to unlock arming rods and open or close a 28-volt line to the fuzing elements.

When the bomb was released from the carrying aircraft the low-voltage thermal battery was connected to the weapon circuits, pullout generators activated low-voltage thermal batteries and started a timer, and two holes in the bomb afterbody were uncovered for pressure sensing. Timer contacts closed 9 seconds after release of the bomb, and deployed the parachute.

(b)(1), (b)(3)

Closure of arming contacts in the baroswitch provided an input to the rotary chopper. The output of this chopper charged the X-unit and armed a trigger circuit and external initiators. The bomb detonated on closure of fuzing elements in the baroswitch if air burst had been chosen. If ground burst had been selected, the bomb detonated when a firing signal was produced by the impact fuze.[64,65]

Field Command notified Sandia January 9, 1961 that Report SC4822(TR), Final Evaluation Report of the Mk 41 Bomb, had been reviewed in coordination with representatives of the interested Services. This review established that the design met all the requirements of the military characteristics, with some minor exceptions.

(b)(1), (b)(3)

The desired weight of 10,000 pounds had been exceeded by 500 pounds, but this was also acceptable in view of Department of Defense desires for the maximum possible yield. It had not been determined whether the bomb would be compatible with Weapon Systems 110A and 125A, since these aircraft were not yet available. Slight deviations in fuzing accuracy were acceptable, in view of the barometric system and the inherent errors of climatology. Thus, the design was declared acceptable to the Department of Defense.[66]

UNCLASSIFIED

20080001763

there were no fractional-kiloton warheads being designed or considered for development with availability dates as early as 1961, which would be compatible with an unmodified HAWK missile. This was due to the small size of the warhead compartment, which was about 13 inches long.

(b)(1), (b)(3)

Since major modifications of the missile were required, it was felt that the implications of increased compartment length versus smaller warhead sizes should be studied further.[10]

The HAWK missile was designed for low-altitude defense and would be used in conjunction with the NIKE missile family. The HAWK weighed 1,250 pounds, and could operate from sea level up to 45,000 feet against single targets and to 30,000 feet against formation targets. It was capable of intercepting targets at ranges of 13 to 19 nautical miles with closing rates of 1,000 to 600 miles per hour.

Picatinny noted that the preliminary requirements included weapon kill as primary capability and carrier kill if weapon kill could not be achieved.

(b)(3)

Operation down to a 1000-foot altitude was desired, although 2500- to 5000-foot altitudes would be acceptable. Picatinny would proceed with a study of yield requirements and investigate the possibility of modifying the HAWK warhead compartment to accept nuclear warheads of the 10- to 12-inch-diameter class.[11]

On January 30, 1957, a member of Picatinny Arsenal met with representatives of Field Command, Radiation Laboratory, and Sandia.

History of the Mk 43 Bomb

In the early 1950's, the trend in military aviation was to fly higher and faster in order to defeat enemy defenses. Air-defense techniques, however, kept pace with increases in aircraft performance, and consequently a shift was made to attacks at low altitudes, where both radar and visual observation became less effective. This resulted in a demand for a weapon that could be released at low altitudes, be rugged enough to survive impact with the target, and then detonate by delayed-action fuze after pilot and aircraft were far enough away to survive the blast.

The Navy had expressed early interest in this type of weapon, and one result was the Mk 8 Bomb that could be used to penetrate water and even concrete submarine pens. However, the Mk 8 was a gun-type device, with an inherent handicap of nuclear inefficiency. The BETTY depth-bomb application of the implosion-type Mk 7 had been produced, as well as the even more rugged design of the Mk 34/LULU. However, both these weapons could withstand only water-entry shock, not impact with harder targets.

As smaller implosion and thermonuclear designs began to appear, and as improved weapon components were developed, the subject of shock-resistant weaponry continued to be periodically raised. The Assistant Secretary of Defense, August 10, 1955, requested the United States Atomic Energy Commission to cooperate with the Navy in a feasibility study of a lightweight, shock-resistant, implosion bomb which could be dropped at high speeds and low altitudes.

The above was followed by a similar letter dated August 17, 1955, requesting the Atomic Energy Commission to cooperate with the Armed Forces Special Weapons Project and the interested Services in a feasibility study of a new family of atomic weapons not more than 18 inches in diameter. One objective of this study was to determine if a weapon with free-fall characteristics and earlier time scales than the HOTPOINT study (which resulted in the Mk 34) could be developed. This was called the TABLELEG project.[1]

On August 31, 1955, the Joint Chiefs of Staff suggested that the foregoing projects be combined into an investigation of a single weapons family, emphasizing common employment characteristics and simplifying storage, handling, transportation, delivery-vehicle compatibility, and delivery tactics.[2] Subsequently, the Assistant Secretary of Defense forwarded this suggestion to the Atomic Energy Commission October 6, 1955, noting that the new weapons family was assigned top priority.[3]

(b)(1), (b)(3)

The initial approach would be to provide a bomb not more than 1500 pounds in weight, and which could survive release at high speeds and low altitudes. This bomb would have minimum tendency to ricochet, be nonpenetrating to any degree that would degrade surface-burst effects, and function reliably when dropped into shallow water against targets such as harbors and dams. The weapon shape would have low drag to permit efficient external carriage on aircraft.

A joint committee, with members from the Atomic Energy Commission and its contractors and representatives of the Department of Defense, was formed and held its first meeting November 17, 1955. This was the TABLELEG Committee, which examined the feasibility of developing a tactical/laydown family of weapons.

In the TABLELEG Committee meeting of December 15, 1955, the Navy proposed that three weapons be developed. A Step I weapon would provide the Navy with an urgently desired laydown weapon by 1958. This bomb would have the capability of being delivered at low altitudes (50 to 200 feet) and at speeds of Mach 0.6 to 1.4. It would have a single, simple time-delay fuze which would allow escape of the slowest carrying aircraft.

(b)(1), (b)(3)

This design was called HOTPOINT, and the bomb was subsequently stockpiled as the Mk 34.

A Step II weapon would be based on the TX-28 design and it, too, would provide the Services with a tactical family of weapons by 1958. This weapon would be

to 1000-g shocks being possible along any axis perpendicular to the longitudinal. The air-burst fuze would have to resist the opening shock of the parachute, estimated to be a maximum of 100 g's for releases at aircraft speeds of Mach 0.95.

The primary power supply would be thermal batteries, activated at time of release of the bomb. Parachute deployment delay timers would also be actuated at bomb release and, after a delay of 1/2 second for externally carried bombs and 1 second for internally carried bombs, would actuate the tail eject and parachute deployment mechanism.

An integrating deceleration switch would prevent weapon arming in the event of parachute failure on retarded deliveries, as it would have to experience a velocity change of 10 g-seconds. An impact switch would operate under a force of 30 g's and initiate a pyrotechnic timer. Operation of a trajectory arm switch for free-fall deliveries would be governed by the pressure differential between the fore and aft sides of a small block on the bomb case. The switch would be designed to close at a minimum velocity of 300 feet per second. A safe-separation timer would contain a spring-powered escapement timing element to close a set of electrical contacts at the end of two preset adjustable timing intervals and a fixed 9-second time. This component would contain two independent timing channels.

(b)(3)

It would have to be repackaged to meet the stringent space requirements of the TX-43, but its system would be similar to previous designs.

The rotary chopper would be a single-channel, motor-driven unit with an integral radio-interference filter. The device would convert battery voltage of 28 volts direct current into alternating voltage of the same magnitude and approximately rectangular waveform. The resultant power pulses would then be applied to a transformer-converter assembly, creating an output of 2400 volts direct current to charge the X-unit capacitor and provide a signal to the external initiators.

The X-unit would have one capacitor, with either a 4-probe gap or puncture switch connected to the central capacitor terminal. If a gap switch was used, four pulse

were expected with the latter application. Since wind-tunnel tests of the release and separation characteristics of internally carried streamlined shapes similar to the TX-43 had not been satisfactory in the past under high-speed conditions, it was essential that the separation problem be investigated as soon as possible.[13]

Field Command replied June 6, 1957, noting that B-47 compatibility could not be achieved without changing the existing design. However, if laydown option only would be acceptable, an internally carried version of the bomb could be provided by removing the air-burst fuze, thus reducing the length of the bomb 15 inches. The bomb could be made compatible with the F-105 by minor relocation of the bomb suspension rack.

Field Command noted that proposed drafts of the military characteristics for the TX-43 had virtually excluded the possibility of internal carriage of the bomb in the B-47, since a minimum length of 153 inches had been specified. It was felt that insistence on including the B-47 as a carrier might jeopardize the existing bomb design or result in a different design for internal carriage. Field Command noted that the design could not be provided with a turnaround design, similar to that of the TX-28, since the spike and parachute had to be at opposite ends of the weapon.[14]

The approved military characteristics for a tactical/laydown family of atomic weapons were meanwhile approved by the Military Liaison Committee June 4, 1957.[15]

(b)(1), (b)(3)

The bomb would be capable of delivery at high speeds and low altitudes with high accuracy and delivery safety. It would be capable of remaining in a completely assembled condition, ready for immediate use and without loss of functional reliability, for a period of at least 6 months.

The maximum diameter would be 18 inches. The length would be compatible with the designated carriers, but would not exceed 170 inches, and the maximum weight would be 1500 pounds.

(b)(1), (b)(3)

(b)(1), (b)(3)

The weapon would be capable of inflight selection of laydown burst, free-fall air burst, or retarded air burst. Four selectable burst heights would be provided, and the fireball was not to touch the ground. Releases at altitudes as low as 200 feet and speeds as high as Mach 0.95 were required, with releases down to 50 feet being desirable. For high-altitude releases, the bomb would be capable of delivery at 60,000 feet and a speed of Mach 2.1.[17]

Wind-tunnel tests had meanwhile been proceeding, and had proved that the fin span, as limited by carrier aircraft, would not provide proper ballistic stability. The span could have been increased by use of a folding-fin mechanism, but this was undesirable, from the standpoints of increased weight and decreased reliability.

(b)(1), (b)(3)

This made it possible to reduce the external diameter of the bomb to 16-1/2 inches, and this diameter, when coupled with the largest fixed fin span permissible, gave marginally acceptable aerodynamic performance.

(b)(1), (b)(3)

Los Alamos and Sandia commented on the tactical/laydown military characteristics in a letter to the Division of Military Application September 10, 1957. It was pointed out that a host of new and sometimes conflicting requirements had been added, and that the weapon design requested was infeasible.

The extensive list of weapon carriers included a wide range of aircraft types, and required the TX-43 to be capable of delivery at velocities ranging from

designs, Mod 0 and Mod 1, had been accepted by the Services as meeting the requirement for a single weapon including both laydown and air-burst capabilities.

It was recognized that the high shock requirements of a laydown design would not allow shipboard removal or insertion of the nuclear assembly. The 200-foot release altitude satisfied the military characteristics, but it was hoped that work would continue toward attainment of a 50-foot capability as soon as possible. 40

(b)(1), (b)(3)

The fuze switch pack was a potted unit containing printed-circuit boards, various explosive switches, diodes and cables. A 28-volt thermal battery was connected to a ready-safe switch operated electrically by the aircraft pilot. An inertial switch formed a safety device to prevent bomb arming in the event of accidental bomb release below minimum delivery speed, or in the event of parachute failure. A minimum force of 3 g's was required to activate this inertial switch, with a minimum of 8 g-seconds needed for complete operation.

A rotary chopper inverter transformed the battery output of 28 volts direct current into an alternating 28-volt rectangular waveform that was stepped up and rectified to provide high-voltage direct current for charging the capacitors of

the X-unit and the external initiators (neutron generators). The capacitor in the neutron generators was charged to a potential of 2200 to 2600 volts.

(b)(1), (b)(3)

Firing of this gap resulted in an arc discharge between two titanium tritide conductors in the source tube, thus producing tritium ions.

Firing of the spark gap allowed an energy storage capacitor to discharge the primary winding of a high-voltage pulse transformer.

(b)(3)

The weapon was provided with four fins, each having a frangible area at the outboard trailing edge. The unreefed ribbon parachute, developed by Wright Air Development Center, was 16 feet in diameter.[41]

Full-scale tests included drops onto a concrete target, at impact velocities of 46 to 117 feet per second, and at angles of 22 to 75 degrees to the horizontal target. Some test vehicles contained high explosives, and others held fuzing and firing components. Two tests were made at a temperature of -55°F. There were three fractures reported, all of which occurred when the weapon spike did not stick in the concrete. The high explosive did not detonate at impact, and the low-temperature units operated normally. Airdrops were started at the Salton Sea Test Base and continued at the Tonopah Test Range, where a 12-inch-thick concrete target became available in late 1960.[43,44]

Tests of the early designs of inertial latching switches showed that an excessively high minimum release speed was required and, for releases below an altitude of 300 feet, closure and lock-in were not accomplished with desired reliability.[45] The switch was redesigned for better operation and, due to a delay in the Mk 43 production schedule, it became possible to supply this new switch in time to meet first Mk 43 Mod 0 Bomb production in April 1961.[46,47,48]

UNCLASSIFIED

The Assistant Secretary of Defense requested the United States Atomic Energy Commission, November 1, 1954, to collaborate with the Navy Bureau of Ordnance in a study to determine the feasibility of developing a rocket-propelled atomic depth charge for attack of fast, deep-diving submarines. Recent improvements in submarine detection equipment had been made, and the Bureau of Ordnance wished to consider application of a nuclear weapon.[1]

The Division of Military Application forwarded the above request to the Santa Fe Operations Office, but pointed out that the scope of the study was quite broad and general, and that, until a particular weapon system had been selected, AEC participation should be confined to informal discussions. Time scales for the study had not been specified, and it was felt that a deliberate and unhurried examination should be conducted.[2]

Some months later, June 29, 1955, the Assistant Secretary of Defense requested a study of the feasibility of producing 10- to 12-inch implosion warheads.[3]

(b)(1), (b)(3)

Longitudinal accelerations of 100 g's for antiaircraft missiles and about 2000 g's for antisubmarine-warfare weapons were prescribed, and it was pointed out that the higher figure was appropriate for those weapons that would have to withstand water entry.

The attendees at the Board meeting felt that it would be possible to produce warheads of the desired size by 1959, in view of effort currently being expended on the XW-25 and XW-30 designs.

(b)(1), (b)(3)

(b)(1), (b)(3)

It was felt that the system could be made rugged enough for use as a depth charge.

Sandia reported that existing pulse transformers for external initiators were fairly bulky, and it was not apparent that their size and weight could be materially reduced. It was hoped that capacitors could be made smaller, and work was in progress on a toroidal design using a single winding, rather than the several individual capacitors used in existing components. However, costs would be high and reliability questionable for some time to come.

It was felt that completion of weapon development on schedule would depend largely on Sandia's work, and it was hoped that one design would be compatible with all carriers. Since NIKE and TERRIER were already available, the study would be based largely on these two missiles. One requirement, however, would be the high g-loading created by water entry, and it was suggested that shock-resistant designs be investigated.[4]

Field Command issued a study report November 1, 1955, which stated that an implosion weapon with an outside diameter of 11.75 inches and maximum length of 24 inches could be developed for use in several weapon delivery systems, including that of an ASROC (or antisubmarine rocket).

(b)(1), (b)(3)

The warhead would require no external power other than short pulses of 28 volts.[5]

(b)(1), (b)(3)

(b)(1), (b)(3)

The ASROC weapon system was described in a report issued by the Naval Ordnance Test Station January 28, 1957. The system had been designed to provide surface ships with a weapon for long-range attack of fast, deep-diving submarines. The system would be able to deliver either an atomic depth charge or an acoustic homing torpedo, and both payloads would use the same fire-control launcher, motor-thrust termination and airframe. The atomic ASROC would have a range from 3,500 yards (2 miles), which was the minimum safe range for launching-ship safety, to 10,000 yards (5-3/4 miles).

Warhead electrical arming would be initiated at water impact when, and only if, minimum safe range had been assured. A fixed time delay of 2 seconds after water impact would be provided to allow for complete warhead arming. Shallow-water hydrostats would assure that the depth charge had entered a water environment. The power source for the high-voltage system for warhead detonation could be removed or reinstalled with the weapon in place on the launcher.

The arming and fuzing functions would be divided into three main phases: Pre-launch, airflight, and underwater operation. Prior to launch, the arm/safe switch would be manually operated to the ARM position. When the rocket motor was ignited at launch, the weapon low-voltage power supply would be activated by the fire-control signal and the range determined by terminating the rocket thrust at the correct velocity to achieve proper range. This termination signal would be furnished by a range control device containing an integrating accelerometer and

(b)(3)

History of the Mk 47 Warhead

The Chief of Naval Operations wrote to the United States Atomic Energy Commission, September 14, 1956, noting that work was proceeding on a Fleet Ballistic Missile powered by solid propellant. Calculations had indicated that if a suitable warhead with a weight of 600 pounds could be produced, the missile could be considerably reduced in size. A smaller missile would offer both operational and logistic advantages to Fleet employment and would permit improvements in missile design. (b)(1), (b)(3)

The Assistant Secretary of Defense notified the Atomic Energy Commission January 9, 1957, that the Department of the Navy was developing the POLARIS, a sea-based, surface-to-surface ballistic missile for use against land targets. The Atomic Energy Commission was requested to cooperate with the Navy and the Armed Forces Special Weapons Project in a joint feasibility study of a warhead for this missile.

The POLARIS, a submarine-launched, two-stage solid-propellant rocket with inertial guidance, would have a diameter of 5 feet, length of 28 feet, gross takeoff weight of 33,000 pounds, and a range from 1,200 to 1,500 nautical miles. The warhead would be carried in the nose cone, and the nuclear device could weigh up to 600 pounds. (b)(1), (b)(3)

It was noted that the warhead parameters were relatively stringent, but that the Navy would accept an interim warhead with a smaller yield. It was felt that the warhead would have to be integrated with the nose cone to properly meet design objectives.[2]

Both the Los Alamos Scientific Laboratory and the University of California Radiation Laboratory were requested to participate in the study, but the major effort was provided by the Radiation Laboratory.[3] A feasibility study report was released May 27, 1957, which stated that no currently stockpiled warhead

was adaptable to POLARIS, but that straightforward development of devices planned for future tests should provide a suitable thermonuclear design. (b)(1), (b)(3)

The Navy was designated cognizant agent for the Department of Defense, with normal Armed Forces Special Weapons Project relationships.[5]

A POLARIS Re-entry Body Coordinating Committee was formed and held its first meeting July 29, 1957. It was noted that the re-entry body would include an aerodynamic cone, heat sink, warhead, adaption kit, and attitude controls. The total re-entry body weight, including warhead, would not exceed 835 pounds. (b)(1), (b)(3)

History of the Mk 48 Shell

The predecessor of the Mk 48 Shell was the Mk 33, an 8-inch-diameter, artillery-fired atomic projectile. While this latter shell was still being designed, the Under Secretary of the Army wrote to the United States Atomic Energy Commission, April 28, 1954, expressing interest in the possibility of developing an even smaller diameter projectile with a very low yield, and a broad study was subsequently authorized by the Secretary of Defense May 14, 1954.

The intent of this study was to investigate the possibility of using implosion techniques in an atomic artillery shell, rather than the gun method used in previous shell designs, but the state of the art was not sufficiently well advanced. Much work was, however, accomplished in the ensuing 12 months by the University of California Radiation Laboratory and resulted in a request from the Secretary of Defense to the Atomic Energy Commission, April 4, 1955, for a feasibility study of an 8-inch shell having advanced nuclear techniques. (b)(1), (b)(3)

(b)(3)

SECRET
RESTRICTED DATA UNCLASSIFIED

The Army informed Sandia November 24, 1961 that nomenclature of the 155mm projectile was changed from T358 to XM454 to prevent unclassified associations indicating the existence of the project for developing the atomic projectile.[27]

An amendment to the military characteristics, approved by the Military Liaison Committee June 26, 1962, deleted surface-burst preclusion. Contact detonation of shell with target was desired.[28] Another amendment was approved by the Military Liaison Committee September 19, 1962. This required that the shell be designed to allow it to be air-dropped in its container and survive impacts causing an 80-g deceleration.[29,30]

Meanwhile, components and complete projectiles had been subjected to laboratory functional and environmental tests simulating operational conditions, and to full-scale howitzer firings in instrumented projectiles. The items were first tested to determine their ability to operate properly as individual components. They were then assembled into subsystems, and finally into complete projectiles, and futher tested to determine their physical and electrical compatibility and their ability to function as a system. These tests were initially conducted under normal laboratory conditions; then under conditions of natural environmental extremes; then under the environments imposed by the application, such as ground handling, howitzer firing, etc.; and finally under the combinations of natural and artificial environments that would be encountered in actual use. All test results indicated that the system was more than adequate.

Production of the first unit, originally scheduled for June 1962, was delayed to October 1962, then to March 1963, and finally to October 1963, with corresponding changes being made to associated program dates. The Mk 48 Mod 0 Shell was given complete engineering release in January 1963, and production of the first projectiles was effected October 26, 1963.[31]

Report SC4871(WD), Final Development Report for the Mk 48 Mod 0 Warhead, was forwarded February 1964 to the Design Review and Acceptance Group, and was

subsequently approved and published in May 1964. (b)(1), (b)(3)

It was integrated with a number of components supplied by the Department of the Army to form the XM454, an artillery-fired atomic projectile designed to be fired from 155mm howitzers equipped with either M1A1 or T258 tubes. The maximum range of the projectile was 14,000 meters, or 8.5 miles. The minimum fuze-setting range was 1650 meters, or about 1 mile, which provided safe distance from nuclear detonation. The projectile was 155mm (6.1 inches) in diameter, 34 inches (5.57 calibers) long, and weighed 120 pounds.

(b)(1), (b)(3)

8/4/59	Military characteristics approved by the Military Liaison Committee.
11/6/59	Sandia forwards development program definition to AEC.

(b)(1), (b)(3)

3/23/60	Military Liaison Committee suspends higher yield requirement.
1/63	Mk 48 Mod 0 Shell design released.
10/26/63	Early production of Mk 48 Mod 0 Shells.
5/64	Final development report approved and published.

Other components included a corona regulator tube, ceramic spark gap, and an inertial or setback switch. If the tube could not be designed to resist firing shock, other methods of regulation were available that could meet requirements of small size, rugged construction, and dependable operation. An extensive reliability study of the spark gap would have to be made. Due to experience gained on other designs, it was felt that the setback switch would impose no particular problems.[13]

The Army informed Sandia July 16, 1958 that, as the caliber of the implosion shell decreased, the magnitude of the associated engineering problems increased. It was therefore suggested that detailed consideration be limited to the design of a shell with a minimum diameter of 155mm. It was recommended that development engineering be authorized for a shell for the 155mm howitzer and the 175mm gun, but that general small-caliber research be continued.

(b)(1), (b)(3)

(b)(1), (b)(3)

(b)(3)

The higher yield, however, was desired and would be retained in the military characteristics.[23]

The Military Liaison Committee forwarded an amendment to the military characteristics May 2, 1960. This required that the XW-48 be compatible with M1A1 and T258 howitzers.[24] The Lawrence Radiation Laboratory and Sandia had previously informed Picatinny Arsenal that it was not possible, either through calculations or completed tests, to estimate with confidence the ability of the projectile to withstand the T258 environment, as Picatinny had indicated that this new application would subject the shell to angular accelerations 25 percent greater than previously anticipated. However, suitable tests would be conducted.[25]

These tests were subsequently made at the Army's Yuma, Arizona, test station. Linear accelerations of 12,000 g's were recorded, together with angular accelerations of 190,000 radians per second per second, the T258 howitzer environment. No premature firings were experienced, and no damage to shell components resulted. Thus, Sandia notified Albuquerque Operations Office January 15, 1961 that the T258 howitzer and XW-48 Shell were compatible.[26]

subsequently approved and published in May 1964. (b)(1), (b)(3)

It was integrated with a number of components supplied by the Department of the Army to form the XM454, an artillery-fired atomic projectile designed to be fired from 155mm howitzers equipped with either M1A1 or T258 tubes. The maximum range of the projectile was 14,000 meters, or 8.5 miles. The minimum fuze-setting range was 1650 meters, or about 1 mile, which provided safe distance from nuclear detonation. The projectile was 155mm (6.1 inches) in diameter, 34 inches (5.57 calibers) long, and weighed 120 pounds.

Mk 49 Mod 3

(b)(1), (b)(3)

1/60	Mk 49 Mod 3 Warhead design released.
3/11/60	Mk 49 Mod 3 Warhead authorized for application to THOR and JUPITER missiles. Early production accomplished by retrofit of Mk 49 Mod 1 Warheads.
6/60	New production of Mk 49 Mod 3 Warheads.
8/16/61	Final evaluation report of Mk 49 Mod 1/3 Warheads accepted by Military.

Mk 49 Mod 4

10/3/58	XW-49-X1 Warhead proposed for use with ablation nose cones.
10/21/59	Proposed ordnance characteristics of XW-49-X1 presented to Special Weapons Development Board.

(b)(1), (b)(3)

4/26/60	Mk 49 Mod 4 design released and early production achieved.
10/4/63	Final development report of Mk 49 Mod 4 accepted by Field Command.

Mk 49 Mod 5

4/24/62	Division of Military Application requests Sandia to provide JUPITER warhead with permissive device to prevent unauthorized detonation.
9/25/62	Mk 49 Mod 5 design released, incorporating coded switch pack.
9/29/62	Mk 49 Mod 3 Warheads retrofitted to Mod 5.
5/64	Final evaluation report of Mod 5 published.

Mk 49 Mod 6

12/63	Authorization released to incorporate self-destruct unit into some Mk 49 Mod 3 Warheads.

3/64	Initial delivery of Mk 49 Mod 6 Warheads.
7/18/65	Final evaluation report of Mod 6 accepted by Field Command.

History of the Mk 49 Warhead

In mid-1956, Los Alamos Scientific Laboratory and Sandia started to investigate warhead designs that could be used in connection with ATLAS and TITAN intercontinental ballistic missiles and JUPITER and THOR intermediate-range ballistic missiles. These studies culminated in development of the XW-35 and XW-35-X1 Warheads.

(b)(1), (b)(3)

The XW-35-X1 was a new configuration designed to produce a higher yield per pound, and was to follow the XW-35 in development by about one year.

Due to delays in missile availability, it became apparent that the XW-35-X1 would become operational at the same time as the earliest of the above missiles (with exception of JUPITER) and that the XW-35 design could be canceled.

(b)(1), (b)(3)

A decision was then made to cancel the XW-35, use the modified XW-28 for JUPITER, and apply the XW-35-X1 to all four missiles.

(b)(3)

Since THOR and JUPITER squadrons were scheduled for deployment in late 1958 and the XW-35-X1 Warhead would not be available in time, modified Mk 28Y1 Warheads would be supplied for the interim period.[1]

A meeting with General Electric, designers of the nose cone for the ATLAS, TITAN and THOR, was held December 9, 1957, and it was noted that the modified Mk 28Y1 Warhead would be renamed the XW-49.[2] This warhead would contain no internal power, as this would be supplied by the missile adaption kit. It was felt that the XW-49 could be produced in 1958.

(b)(1), (b)(3)

(b)(1), (b)(3) The warhead would be sealed and pressurized. The firing system would be checked after assembly and subsequently require only continuity and pressure monitoring in field or stockpile. There would be no component replacement permitted and no reason to break the warhead seal after initial assembly.[1]

The Mk 49 Mod 0 Warhead was design released in March 1958,[3] and early units entered stockpile in September 1958.[4] Sandia presented Report SC4161(TR), Description and Status Report at Design Release of the W49-0 Warhead, to the April 23, 1958 meeting of the Special Weapons Development Board.[5] The report noted that the Mk 49 Mod 0 was a thermonuclear warhead designed for early-emergency-capability use in JUPITER and THOR missiles. The warhead was 20 inches in diameter and 54.2 inches in length, exclusive of mounting provisions.

(b)(1), (b)(3) Field testing was limited to monitoring the internal warhead pressure every 30 days and checking electrical continuity just before mating the warhead to missile re-entry vehicle.

The report noted that the Mk 49 Mod 0 was the first warhead system to use a rotary chopper inverter/converter to change low-voltage direct current (28 volts) into high-voltage direct current (2200 volts). When proper signals were applied to both chopper and converter, the applied voltage was interrupted, transformed, rectified and used to charge the X-unit capacitor storage bank. To complete arming functions, a low-voltage direct current was applied to boosting-gas reservoir and valve assembly to release deuterium-tritium gas into the sealed pit.

The Mk 49 Mod 0 Warhead could be fired by either one of two signals. The air-burst option applied a 28-volt direct-current signal to a high-turns-ratio, low-impedance pulse transformer. The stepped-up voltage was applied to one probe of a dual-probe spark gap, ionizing the gap and releasing energy stored in the X-unit capacitor bank to the detonators, firing the warhead.

In the contact-burst option, a 250-volt direct-current signal was developed by contact crystals and applied to the grid of a cold-cathode thyratron trigger tube,

causing the tube to conduct. This discharged the capacitor in the plate circuit through the primary of the pulse transformer, and voltage generated in the secondary was applied to the second probe of the spark gap. This ionized the gap, the capacitor bank discharged into the detonators, and the warhead detonated.

(b)(1), (b)(3)

The firing system included X-unit, trigger circuit, rotary choppers, converter, arm/safe switch, and filter package. The boosting-gas reservoir and valve were mounted within the warhead pressure container. This container, composed of warhead case and pressure cover, housed warhead components and protected them from storage and operational environments. A pressure switch and humidity indicator were provided within the container to monitor internal pressure and humidity.

(b)(1), (b)(3)

Based on relative results of these two tests, and the fact that the nuclear testing

SECRET
RESTRICTED DATA

moratorium was approaching, Los Alamos proposed, June 16, 1958, that the XW-35 program be canceled in favor of the XW-49. This suggestion was approved by the Division of Military Application, July 3, 1958.[7]

The United States Atomic Energy Commission wrote to the Deputy Secretary of Defense, July 8, 1958, reporting the decision to abandon the XW-35 program in favor of the XW-49.

(b)(1), (b)(3)

Sandia notified Albuquerque Operations Office, July 17, 1958, that the Mk 49Y1 Mod 0 Warhead would be delivered to stockpile in the near future. However, it did not appear appropriate to make the release until an acceptable number of successful warhead flights had been completed in various missiles. Schedules called for four THOR systems flights, and three system and two component flights in JUPITER by late 1958; and these would be the bare minimum to support an application release of warhead and missile. However, before the end of 1958, Sandia would issue an emergency-capability release to permit warhead-missile deployment pending availability of adequate flight-test information.[10]

An amended release of the Mk 49Y1 Mod 0 Warhead was made August 29, 1958. It was noted that satisfactory tests of this warhead had been performed in simulated environments typical of JUPITER and THOR, and application release for use in these missiles was authorized.[11]

By April 29, 1959, three warheads had been flight tested on THOR. Flight data indicated that the warhead experienced a relatively mild environment and that the warheads functioned as intended, in both air and contact burst. Six warheads had been tested on JUPITER. Of these, one test was successful, two were unsuccessful due to missile failure, two unsuccessful due to nose-cone failure, and one unsuccessful due to

SECRET
RESTRICTED DATA

SECRET
RESTRICTED DATA

fuzing-system failure. Despite this poor showing, it was noted that these warheads had also experienced a relatively mild environment and that the weapons would have functioned properly if the correct fuzing signal had been given.[12]

The Mk 49Y2 Mod 0 Warhead was released July 2, 1959 for use with the ATLAS missile. One flight had been made, and this also indicated that the warhead could adequately resist the missile environment.[13] The Mk 49Y1 Mod 0 for the ATLAS was released July 29, 1959.[14]

Mk 49 Mod 1 Warhead

Development of a Mk 49 inertial switch was ~~prepared~~ proposed in May 1958. This device would prevent warhead arming until the weapon had experienced a re-entry deceleration environment, and prevent premature detonation caused by tester malfunctions, procedural mistakes, or acts of sabotage.[15]

An amendment to the military characteristics was approved by the Military Liaison Committee October 21, 1958. This requested that a sensing device be built into the Mk 49 Warhead, to be actuated as late in the missile acceleration phase as possible, so as to reduce the possibility of nuclear detonation through accident or sabotage.[16] The Department of Defense had requested that this device be located so that access was difficult and time-consuming, and to protect against fire or other accidents. It was suggested that all existing Mod 0 Warheads be retrofitted with the device, thus resulting in the Mod 1.

Initial release of Mk 49Y1 Mod 1 and Mk 49Y2 Mod 1 Warheads was made in June 1959, and early production was attained in October 1959 by retrofit of Mod 0 Warheads. The Mk 49 Mod 1 was identical in all respects to the Mk 49 Mod 0, with exception of the inertial switch. This switch closed and latched after experiencing a force of 3 to 10 g's, with a total input of 10 g-seconds.

Three 28-volt direct-current inputs were required for arming. These could be received simultaneously, but, if in sequence, the order had to be as follows: (1) Continuous input to the chopper motor, (2) continuous input to the voltage converter,

SECRET
RESTRICTED DATA

and (3) pulsed or continuous input to the boosting-gas valve.

(b)(3)

Two alternate methods of firing the trigger circuit were provided. The first was 28-volt direct current, and was used only in the air-burst option. The other was a 250-volt direct-current pulse, and could be used for either ground or air-burst.

Fuzing signals varied with the missile. JUPITER issued signals singly, in the above order, for arming, by cam-actuated switches on a safing and arming sequencer. Either a radar-air-burst or a contact-crystal signal was then received. The ATLAS and THOR fuzing system provided arming signals simultaneously and detonated the warhead by means of a baroswitch for air-burst option or piezoelectric crystals in the contact option.[17]

Mk 49 Mod 2 Warhead

The Mk 49 Mod 2 Warhead would have been incorporated in the Mk 3 re-entry vehicle in the ATLAS missile. The design would have been internally initiated, as in Mods 0 and 1. A decision to change to external initiators (see the Mk 49 Mod 3 Warhead) resulted in canceling the Mod 2, prior to production, in favor of the Mk 49 Mod 4.

Mk 49 Mod 3 Warhead

A product change proposal dated November 5, 1959 was designed to conserve reactor products.

(b)(1), (b)(3)

The Mk 49 Mod 3 Warhead was design released in January 1960, and authorization for use of this warhead with JUPITER and THOR missiles was issued March 11, 1960.[19] Early production by retrofit of Mk 49 Mod 1's was accomplished during March 1960, and new production started in June 1960.

(b)(1), (b)(3)

The electrical system consisted of the Mk 28 capacitor bank

Mod 0 Warhead, but a new warhead case and pressure cover would be provided. The case would have provisions for mounting nose cap and flare skirt, and the pressure cover would have to withstand the loading created by attachment to the missile. The portion of the warhead case exposed in the re-entry vehicle would be covered with ablation material.[22]

Sandia presented the development program definition of the XW-49-X1 to Albuquerque Operations Office March 16, 1959. Warhead development was directed toward design release in May 1959 and early production in February 1960. The new warhead case would contain modified Mk 49 Mod 0 plastic, same nuclear system, and Mk 49 Mod 1 firing set.[16]

Sandia presented Report SC4293(TR), Proposed Ordnance Characteristics of the XW-49-X1 Warhead, to the October 21, 1959 meeting of the Special Weapons Development Board.[24] The report noted that the warhead was being designed for incorporation in the Mk 3 re-entry vehicle. Carry-over components from the Mk 49 Mod 0 and Mod 1 Warheads would be used wherever possible. Significant changes included major redesign of warhead case section, new interface provisions, and improved sealing features.

(b)(3)

The report was accepted and forwarded to the Division of Military Application.[25]

(b)(1), (b)(3)

Design release was scheduled for January 1960 and early production for April 1960.

(b)(3)

This change would lengthen the warhead by 2.1 inches. The major diameter would be 20 inches plus ablating material, maximum length 57.9 inches plus electrical connectors, and the weight about 1640 pounds without ablation material and 1732 pounds with ablation material.

(b)(1), (b)(3)

SECRET
RESTRICTED DATA

(b)(3)

Mk 49 Mod 5

On April 24, 1962, the Division of Military Application requested that the JUPITER warhead be provided with a permissive device to prevent unauthorized detonation.[32] Sandia stated that an expedited program could produce retrofit kits by late September 1962. To be compatible with the limited space available in the warhead firing section, separate environmental sensing devices and code switches would be installed.

A joint working group was established and met initially May 11, 1962. It was noted that this change would produce the Mk 49 Mod 5 and would increase the warhead weight by 12 pounds. The design was released September 25, 1962 and, within 4 days, two warheads had been retrofitted.[33,34] The Mod 5's were produced by retrofit of Mod 3's and involved replacing an inertial switch pack with a coded switch pack and substituting a new 2-piece pressure cover.[35]

Report SC4780(WD), Final Evaluation Report for the Mk 49 Mod 5 Warhead, was published in May 1964. This noted that permission had been given to deviate from normal development and production procedures in order to meet the retrofit date. Conversion hardware was produced from development rather than production drawings, the design group was given responsibility for acceptance of components, and all hardware, where possible, was 100-percent tested to establish its functional, electrical, structural and interchangeability characteristics.

The system operation of the Mk 49 Mod 5 was the same as the Mod 3, except that the environmental-sensing-device switches were not cross channeled, and therefore any switch failure would cause failure on one channel. Prior to launch, the coded switches were remotely armed to provide continuity through that part of the system.[36]

Timetable of Mk 50 Events

Early 1955 — Army Ordnance Corps requests Bell Telephone Laboratories to evaluate 1960-1970 air-defense problems. NIKE ZEUS antimissile missile proposed.

4/9/57 — Assistant Secretary of Defense requests United States Atomic Energy Commission to study feasibility of nuclear warhead for NIKE ZEUS.

(b)(1), (b)(3)

1/21/58 — Discussion of warhead for PERSHING, a surface-to-surface ballistic missile. Both Los Alamos Scientific Laboratory and University of California Radiation Laboratory propose warhead designs for PERSHING.

2/6/58 — Feasibility study of PERSHING warhead issued. Two warhead yields and weights proposed.

2/10/58 — Division of Military Application suggests that responsibility for development of NIKE ZEUS warhead be assigned to Los Alamos, due to number of programs assigned to the Radiation Laboratory.

3/3/58 — Assistant Secretary of Defense requests Atomic Energy Commission to develop warhead for NIKE ZEUS.

4/4/58 — Assistant Secretary of Defense requests Atomic Energy Commission to develop warhead for MINUTEMAN, an intercontinental ballistic missile.

5/6/58 — Albuquerque Operations Office reports completion of MINUTEMAN warhead study to Division of Military Application.

(b)(1), (b)(3)

Application of same warhead to NIKE ZEUS suggested.

5/21/58 — Assistant Secretary of Defense requests Atomic Energy Commission to conduct further feasibility study of warheads for PERSHING in two weight classes, 300 and 600 pounds.

(b)(1), (b)(3)

6/4/58 — Military Liaison Committee accepts proposal of Divison of Military Application that one warhead be developed for NIKE ZEUS, MINUTEMAN, PERSHING and HOPI missiles, with weight of 350 pounds.

On March 28, 1958, another missile program was proposed when the Military Liaison Committee requested the Atomic Energy Commission to develop a suitable warhead for MINUTEMAN. This was a three-stage, solid-propellant, intercontinental ballistic missile, the upper two stages of which could be used as an intermediate-range missile and the top stage as a short-range missile. The missile could carry either a 300- or 550-pound warhead, and it was anticipated that the missile system would be operational in mid-1962, with warheads being required in large numbers.[13] This program was subsequently authorized by the Assistant Secretary of Defense.[14]

Albuquerque Operations Office sent a teletype to the Division of Military Application May 6, 1958, reporting completion of the MINUTEMAN warhead study.

(b)(1), (b)(3)

The Assistant Secretary of Defense, May 21, 1958, requested the Atomic Energy Commission to cooperate in another feasibility study of warheads for the PERSHING missile system. Two warhead weight classes would be considered; 300 and 600 pounds. For the 300-pound design, the diameter would be less than 15 inches and the length about 40 inches. The 600-pound weapon would be about 18 inches in diameter and the length less than 50 inches.

(b)(1), (b)(3)

Availability date for both warheads would be compatible with missile development in late 1962, and both designs would be required in relatively large numbers.[16]

(b)(1), (b)(3)

(b)(1), (b)(3)

The Division of Military Application had suggested that a single warhead be developed for the NIKE ZEUS, MINUTEMAN, PERSHING and HOPI missile systems, and this proposal was accepted by the Military Liaison Committee June 4, 1958. The Services felt that the diameter of this universal warhead should be from 12 to 14 inches, length 38 to 44 inches, and weight about 350 pounds.[17]

The Division of Military Application forwarded the request for a feasibility study of two warheads for the PERSHING missile to Albuquerque Operations Office June 24, 1958. It was noted that activities in Operation Hardtack were directly related to this study, and that any report should be deferred until test results had been analyzed.[18]

Military characteristics for the NIKE ZEUS missile warhead were released by the Military Liaison Committee July 15, 1958. These noted that the warhead should be rugged, reliable and simple in design; easy and safe to test, monitor, inspect, store, transport and handle; be designed to minimize possibility of human error; and require a minimum of operational tests and maintenance.

(b)(1), (b)(3)

The warhead would be capable of remaining in alert condition on the launcher, ready to fire within 15 seconds, for a period of at least 4 years.[19]

These characteristics were forwarded by the Division of Military Application to Albuquerque Operations Office, August 6, 1958. It was requested that advice concerning warhead parameters be issued as soon as possible, together with information as to whether a single warhead could be designed for all four missiles.[20]

desired weights and yields could be developed on time scales compatible with the missile. The 650-pound warhead would be provided by minor rework of the XW-47 Warhead, and the 350-pound warhead would be furnished by the XW-50.[26]

(b)(1), (b)(3)

It was felt that the NIKE ZEUS could accept a warhead weighing up to 400 pounds, and it was requested that the Military be queried whether the XW-50 weight could be increased to this figure.

(b)(1), (b)(3)

Subsequently, the Air Force noted that MINUTEMAN could carry a 600-pound warhead, and it was decided to apply the XW-56 Warhead to this missile.[28] The HOPI missile was eventually dropped from consideration.

(b)(1), (b)(3)

The Director of Defense Research and Engineering notified the Military Liaison Committee June 19, 1959 that a review had been made of possible nuclear devices to be used in the XW-50 Warhead.

(b)(1), (b)(3)

The foregoing was followed by a letter from the Director of Defense Research and Engineering to the Atomic Energy Commission June 24, 1959, noting that the Joint Chiefs of Staff had determined that an operational requirement existed for

(b)(1), (b)(3)

The warhead was 14 inches in diameter, 15-3/8 inches at the mounting flange, 44 inches long and weighed about 412 pounds. Production of the XW-50-X1 was authorized in June 1961.[43]

(b)(1), (b)(3)

The Division of Military Application had requested that a prescribed action link be provided for the Mk 50/PERSHING.[45] After considerable study, Sandia notified Albuquerque Operations Office July 30, 1962 that incorporation of such device would make the warhead electrically incompatible with NIKE ZEUS. Modification was required, since the limited internal volume of the warhead required removal of self-destruct transverters to provide enough room for the prescribed action link. The device would be included in warhead production by late 1962, and the modified design would be called the Mk 50 Mod 1. Mk 50 Mod 0 designs for the NIKE ZEUS, released in December 1961, would be maintained in active status, but no production was authorized.[46]

Sandia subsequently notified Albuquerque Operations Office that diversion of firing sets for approaching test series would delay production of Mk 50 Mod 1's to March 1963. It was felt that this would allow the Army sufficient time to meet the overseas deployment date of March 1964 for PERSHING.[47]

Field Command notified Sandia September 14, 1962 that Report SC4555(WD), Interim Development Report for the Mk 50, had been reviewed in coordination with representatives of the interested Services. The review established that the design met all requirements of the approved military characteristics, except for the following: The warhead was slightly overweight, and this was acceptable. The ability of the warhead to withstand storage for 4 years was still under study. It was requested that a letter addendum be prepared to cover the Mk 50 Mod 1 design; otherwise, the report was acceptable to the Department of Defense.[48]

On October 19, 1962, Albuquerque Operations Office approved nomenclature for the Mk 50 Mod 1.[49]

(b)(1), (b)(3)

The firing set in the Mk 50 Mod 1 would not have a self-destruct system, but would incorporate a prescribed action link for PERSHING application only.[50]

An amendment to the military characteristics was released December 11, 1962. This required that a coded arming control device or prescribed action link be incorporated in the warhead for PERSHING application to provide an additional measure of command control.

(b)(3)

The device would be capable of being enabled while the missile was in the ready-to-launch condition. Errors in encoding, decoding, recoding, enabling and disenabling would not cause personal injury or weapon destruction.[51]

Early production of the Mk 50 Mod 1 Warhead was accomplished in March 1963. No production of Mk 50 Mod 0 for application to the NIKE ZEUS missile was authorized.

Timetable of XW-51 Events

2/7/58 Assistant Secretary of Defense requests United States Atomic Energy Commission to assist in feasibility study of warhead for the FALCON, an Air Force air-to-air missile.

2/18/58 Phase 2 feasibility study reports that FALCON warhead could not be developed by February 1960. (b)(1), (b)(3)

2/19/58 Assistant Secretary of Defense requests Atomic Energy Commission to study feasibility of warhead for an Army ground-to-ground missile. Consideration to be given to a design that could also be used with the FALCON.

3/19/58 Special Weapons Development Board discusses NUTCRACKER weapons.

(b)(1), (b)(3)

(b)(1), (b)(3)

4/23/58 Special Weapons Development Board studies DAVY CROCKETT, an Army ground-to-ground missile.

(b)(1), (b)(3)

Sandia starts component development.

6/23/58 Assistant Secretary of Defense requests Atomic Energy Commission to develop one warhead for both FALCON and DAVY CROCKETT applications. An improved nuclear design, using less plutonium, to be provided as soon as possible.

7/16/58 Division of Military Application suggests that the Radiation Laboratory be assigned nuclear development responsibility for FALCON and DAVY CROCKETT warheads.

(b)(1), (b)(3)

9/24/58 Nomenclature of XW-51 assigned to FALCON and DAVY CROCKETT warhead development.

(b)(1), (b)(3)

It was expected that a fairly large quantity of these weapons would be required, with early deliveries starting in February 1960.[3,4]

The feasibility report was released by the Air Force Special Weapons Center February 18, 1958, and concluded that existing weapon commitments would not permit development of a warhead compatible with FALCON and which could meet the desired operational availability date.

(b)(1), (b)(3)

The Assistant Secretary of Defense notified the Atomic Energy Commission February 19, 1958 that the Army desired a lightweight, simple, ground-to-ground nuclear-weapon delivery system which could carry a small, low-yield warhead. This system would be used by the Battle Groups of the Pentomic Divisions. Study had indicated that an acceptable system might be developed in a relatively short period of time, and consideration of a suitable warhead was requested.

(b)(1), (b)(3)

It was hoped that the design could be produced by 1960, and it was requested that consideration be given to a warhead that could also be applied to the FALCON missile.[2]

The Special Weapons Development Board met March 19, 1958, and discussed a proposed series of low-yield, nuclear, ground-to-ground, close-support devices called NUTCRACKER which would supplement existing weapon systems. These devices would provide mobility, ability to fire on short notice, would limit effects to the Commander's area of responsibility, assure safety to friendly troops, and result in minimum damage to nontarget areas.

Since recoilless rifles had light weight and inherent accuracy, it was felt that these weapons might be used to deliver a nuclear payload. Sandia had previously

requested Frankford Arsenal to investigate the environment that a weapon launched from a recoilless rifle would experience, and results of the study had indicated that the rifle would subject the warhead to lower setback forces than were created by existing atomic artillery shells.

As a result of the study, two rifle systems had been proposed. One would have a diameter of 6 inches and be spigot-fired, with the diameter of the projectile being larger than the rifle bore. The other would have a diameter of 13 inches. The rifle barrels would be made of fiberglass and be discarded after each round.

(b)(1), (b)(3)

University of California Radiation Laboratory personnel described a warhead that could be used in the NUTCRACKER series.

(b)(1), (b)(3)

The Special Weapons Development Board met April 23, 1958, and noted that the DAVY CROCKETT, a member of the NUTCRACKER series suggested by Sandia, would be spigot-fired from a 6-inch recoilless rifle.[8] The system would have a useful range of 350 to 2000 meters, an overall weight of about 100 pounds, and could be transported by two men.

(b)(1), (b)(3)

A cruciform-shaped afterbody would be 33 inches long, and the range could be extended by providing a longer afterbody.[9]

(b)(1), (b)(3)

(b)(1), (b)(3)

Sandia started component development work. A safety switch would be needed for the DAVY CROCKETT application that would sense acceleration, but would not operate unless a minimum level of 1000 g's was experienced. A squib-initiated 28-volt thermal battery would be required with a rise time of less than 1 second and an output of 4 amperes. A timer would be squib-initiated and leave a 5-second interval.[11]

The Assistant Secretary of Defense notified the United States Atomic Energy Commission June 23, 1958, that it was technically feasible to develop suitable warheads for the FALCON or GAR-11 and the DAVY CROCKETT or the Battle Group Atomic Delivery System, and the Joint Chiefs of Staff had established a requirement for a single warhead for both applications.

(b)(1), (b)(3)

Sandia-Livermore sent a teletype to Albuquerque Operations Office, June 24, 1958, noting that the FALCON and DAVY CROCKETT missiles had different acceleration regimes. The FALCON experienced a boost phase of about 20 g's for 2 seconds, producing a speed of about 1700 feet per second above the velocity of the launch aircraft. The DAVY CROCKETT experienced an acceleration of 2500 g's, resulting in a speed of 500 feet per second. It appeared doubtful whether the same type of safety switch (to prevent premature detonation) could be designed and used.[13]

RESTRICTED DATA

The Division of Military Application requested Albuquerque Operations Office, July 16, 1958, to assign nuclear development responsibilities for the FALCON and DAVY CROCKETT warheads to the Radiation Laboratory. It was hoped that one warhead could be provided for both applications.[14]

The Army notified Sandia July 23, 1958, that recent developments in the Middle East had emphasized DAVY CROCKETT desirability, and that the Army had internally accorded this program the highest possible priority. The Secretary of the Army had recommended to the Department of Defense that this system be given a national urgency equal to that of the intercontinental ballistic missile and the antimissile missile.[15]

(b)(1), (b)(3)

Sandia notified Albuquerque Operations Office September 24, 1958, that nomenclature of XW-51 had been assigned to the warhead.[17] The military characteristics for an

RESTRICTED DATA

atomic warhead for the FALCON and DAVY CROCKETT were approved by the Military Liaison Committee October 21, 1958.

(b)(1), (b)(3)

If technically feasible, a warhead for both applications would be provided in one basic design.

Maximum economy of nuclear material was a major design objective. Other features of interest included safety from nuclear disaster to friendly troops and installations, acceptable reliability, minimum weight, simplicity and ease of maintenance, and minimum use of reactor products.[18]

The Division of Military Application, November 14, 1958, requested that the Lawrence Radiation Laboratory and Sandia join with the Air Force and the Army in development engineering of the FALCON and DAVY CROCKETT warhead installations.[19]

(b)(1), (b)(3)

The Group would reconvene December 4, 1958.[20]

(b)(3)

The design would also meet requirements for the DAVY CROCKETT system and would be capable of withstanding the acceleration imparted to the warhead by the recoilless rifle.

Glossary of XW-51 Terms

Air Force Special Weapons Center -- That element of the Air Force Systems Command having to do with compatibility testing of nuclear devices with aircraft. Located at Kirtland Air Force Base, Albuquerque, New Mexico.

Albuquerque Operations Office -- The local office of the Atomic Energy Commission (AEC) concerned with the operations of Sandia Corporation.

Armed Forces Special Weapons Project -- An interdepartmental agency formed to handle military functions related to atomic weapons.

Assistant Secretary of Defense -- Created by Department of Defense directive, June 30, 1953, as part of DOD reorganization. Handles research and development activities of the DOD.

(b)(1), (b)(3)

Department of Defense -- The Armed Forces, i.e., the Army, Navy and Air Force.

Division of Military Application -- An AEC office that functions as liaison between the Military and weapons designers and producers.

Field Command -- The local office of the Armed Forces Special Weapons Project (Defense Atomic Support Agency), located on Sandia Base, Albuquerque, New Mexico.

(b)(1), (b)(3)

Hardtack -- A nuclear series of 72 tests. Hardtack I was held at the Pacific Proving Grounds from April 28 to August 18, 1958. The decision to declare a moratorium on testing resulted in Hardtack II, held at the Nevada Test Site between September 12 and October 30, 1958.

(b)(1), (b)(3)

(b)(1), (b)(3)

Joint Chiefs of Staff -- A group composed of the Chiefs of Staff of the Army, Navy and Air Force, to determine policy and develop joint strategic objectives of the Armed Forces.

Kilogram -- A metric weight approximating 2.2 pounds.

Kiloton -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-kiloton yield is equivalent to the detonation effect of 1000 tons of high explosive.

Lawrence Radiation Laboratory -- A change of name for the University of California Radiation Laboratory (which see), effective October 1958.

Lenses -- As applied to nuclear weapons, lenses are elements of the high-explosive sphere, which are designed to produce an implosion. The lens charge is composed of high explosives of different burning rates and is so constructed and shaped as to change the explosion initiated by the detonators into an implosive force which converges smoothly on the nuclear materials.

Los Alamos Scientific Laboratory -- A nuclear design organization located at Los Alamos, New Mexico.

Military Characteristics -- The attributes of a weapon that are desired by the Military.

Military Liaison Committee -- A Department of Defense committee established by the Atomic Energy Act to advise and consult with the AEC on all matters relating to military applications of atomic energy.

(b)(1), (b)(3)

One-Point-Safe Weapon -- A weapon that will not produce a nuclear yield when detonated at one point on the surface of the high explosive.

Operation Hardtack -- See Hardtack.

(b)(3)

(b)(1), (b)(3)

Radar -- Named for Radio Detecting and Ranging. Radars emit a pulse of high-frequency energy and measure the time lapse from that transmission to receipt of a reflected electrical "echo" from an object. This time measurement determines the distance of the object from the transmitting antenna of the radar.

Special Weapons Development Board -- Change of name for the Sandia Weapons Development Board, effective May 14, 1952.

Squib -- A device containing a small powder charge. When detonated, the resulting gas pressure closes a switch or performs a similar action. A light, quick-acting, one-shot device.

Thermal Battery -- A battery whose electrolyte is in a solid state while inactive. To activate, heat is applied to this electrolyte, melting it and putting the battery into active output condition.

Ton (Yield) -- A means of measuring the yield of an atomic device by comparing its output with the effect of an explosion of TNT. A 1-ton yield is equivalent to the detonation effect of 2000 pounds of high explosive.

Tritium -- The hydrogen isotope of mass number 3.

University of California Radiation Laboratory -- A laboratory established at Livermore, California. Initially founded for work on thermonuclear designs.

Uranium-235 -- A radioactive element, an isotope of uranium-238.

Uranium-238 -- A radioactive element, atomic number 92. Natural uranium contains about 99.3-percent uranium-238; the rest is uranium-235.

Warhead -- A weapon carried to the target by missile.

History of the Mk 52 Warhead

The Mk 52 resulted from the effort to provide the Army SERGEANT rocket with an appropriate nuclear warhead. An early meeting was held September 25, 1953, with representatives of the missile contractor (the Jet Propulsion Laboratory of the California Institute of Technology), the Armed Forces Special Weapons Project and Sandia in attendance. It was noted that the SERGEANT would be 30 inches in diameter, 35 feet long, weigh 10,000 pounds, and be able to carry a 1500-pound warhead to a range of 75 to 100 miles. The SERGEANT was a surface-to-surface, solid-propellant guided rocket, intended as a replacement for the CORPORAL, which carried a Mk 7 Warhead.[1]

The Division of Military Application, in a letter dated November 27, 1953, noted that the SERGEANT had not yet been approved as an atomic weapon carrier, and that Sandia participation should be limited to liaison and interchange of information to assist the Jet Propulsion Laboratory in preparing a system proposal.[2]

Little immediate warhead work was performed, but by late May 1955 Sandia studies indicated that it would be possible to provide a warhead to meet missile requirements of reliability, simplicity, ease of operation, freedom from countermeasures, ruggedness and safety. A thermonuclear design was suggested, since the higher yield and efficiency of such weapon would have size and weight advantages that would aid in achieving missile objectives.[3]

The Assistant Secretary of Defense notified the United States Atomic Energy Commission August 29, 1955 that early production of the SERGEANT missile was scheduled for May 1959. Request was made for participation in a joint feasibility study of suitable warheads for the system, in cooperation with the Army and the Armed Forces Special Weapons Project, and this request was subsequently forwarded to both Santa Fe and San Francisco Operations Offices.[4]

By mid-April 1956, two successful SERGEANT flight tests had taken place. The rocket was inertially guided, and continuous guidance correction during the missile flight

was provided. The range was controlled by extending the drag brakes of the missile for a specified length of time.

(b)(1), (b)(3)

The Army's Picatinny Arsenal had been studying possible fuzing systems and proposed that a radiating-type fuze be used, with options of air burst with contact backup, ground burst, and air burst with contact preclusion. It was felt that either inertial or barometric fuzing would not be sufficiently precise, as it was hoped to develop a burst-height accuracy of ±50 feet.

(b)(3)

A feasibility study group had meanwhile been formed, with representatives from Field Command, Picatinny Arsenal and Sandia. This group reported, July 25, 1956, that it would be about a year and a half before firm atomic-warhead information would be required for the SERGEANT program, and that consideration of warhead designs was premature. It was proposed that warhead selection, as well as completion of the feasibility study, be deferred until after the 1957 nuclear test series.[6]

Picatinny Arsenal requested information on the one-point-detonation characteristics of the nuclear design, so that an adequate safing system could be devised.

(b)(1), (b)(3)

Rocket design continued, with little work being done on the warhead. The feasibility study group again met December 3-4, 1957, and learned that the rocket operational availability date of mid-1962 might be shortened by almost a year.

(b)(1), (b)(3)

(b)(1), (b)(3)

Picatinny Arsenal released the feasibility study report December 31. 1957.

(b)(1), (b)(3)

Typical targets were fighter airfields, command posts, headquarters, communication centers, supply and logistic installations, troop units, tanks and artillery.

The rocket was 31 inches in diameter, 31 feet long, and weighed 10,000 pounds at launch. It was composed of four major sections; propulsion, fins, guidance and warhead. The solid-propellant motor had a burning time of 28 seconds and reached a peak longitudinal acceleration of about 10 g's at burnout. The range was controlled by four simultaneously activated drag brakes which extended and retracted three times during the upward leg of the missile trajectory. The time that the brakes remained extended was determined by an internal computer which continuously compared the actual position and velocity of the rocket, as determined by an inertial platform, with the reference trajectory that the missile should be following for that particular range.

Time of flight varied between 120 and 200 seconds. About 22 seconds prior to impact, an arming decision was made, based on establishment of the square or window in space through which the missile would have to pass in order to receive an affirmative arming command. During the final 20 seconds of flight any necessary corrective maneuvers were performed.

The nose section for the warhead would have an overall length of 139 inches, with the base of the section having a diameter of 31 inches and tapering to a point. The warhead installation would be limited to a weight of 1500 pounds, of which 1250 pounds were allocated for the warhead. The warhead itself could have a maximum length of 65 inches.

(b)(1), (b)(3)

Warhead installation flights would start in April 1958, final systems demonstration of

(b)(1), (b)(3)

The Assistant Secretary of Defense notified the United States Atomic Energy Commission, October 10, 1958, that some time had passed since the Joint Chiefs of Staff had established a military requirement for a nuclear warhead for SERGEANT, but that a request for warhead development had been delayed pending a decision on the missile system itself.

(b)(1), (b)(2), (b)(3)

The Army would be the cognizant agent for the Department of Defense portion of the development, with normal Armed Forces Special Weapons Project participation.[13]

A Joint AEC/DOD Warhead Committee for SERGEANT was appointed and held its first meeting November 17, 1958. It was noted that the missile was in an advanced state of development and it appeared likely that the warhead flight-test program could proceed without major interruptions.

It was reported that considerable work had been accomplished on the missile fuzing system, but this had been designed to meet TX-43 requirements and might not be entirely applicable. There would be two options, air burst and contact burst, but no contact backup for the air-burst option. The fuze would be baro-armed and radar-fired in the air-burst option. Both impact crystals and crush switches would be considered for contact fuzing. At an altitude of 18,500 feet above the firing altitude, a baro offset switch would interrogate an arming-decision device to determine whether it was safe to arm the warhead. If trajectory and attitude were within limits, arming and firing signals would be generated in proper sequence.[14]

A SERGEANT meeting was held December 11-12, 1958. There was general agreement by all except Picatinny that a self-destruct feature was not desired. Development time scales were felt reasonable, with the exception of early flight-test dates which might be difficult to meet. The warhead would be design released in May 1960, with early production in May 1961, and would achieve operational capability in August 1961. Sandia proposed that a chopper-converter system be used. This would be a two-channel system, each channel of which would require a separate arming and charging signal. It was felt that a trajectory sensing or goof-proof device should be included, to provide ground handling safety.[15]

Sandia notified Albuquerque Operations Office, January 19, 1959, that it appeared entirely feasible to develop a warhead for the SERGEANT by August 1961, but that no firm commitment would be made until military characteristics had been received and evaluated.

(b)(1), (b)(3)

Military characteristics for the XW-52/SERGEANT were approved by the Military Liaison Committee January 20, 1959.

(b)(1), (b)(3)

Development authorization was released February 27, 1959.[18]

(b)(1), (b)(3)

Sandia forwarded the development program definition of the warhead to Albuquerque Operations Office April 22, 1959.

(b)(1), (b)(3)

Power would be supplied by the missile adaption kit. Sandia felt that the military characteristics required certain features that might limit use of the warhead for other applications or might compromise reliability, or were more appropriately adaption-kit requirements, and recommended changes were being discussed.[21]

Sandia wrote to the Division of Military Application April 29, 1959, commenting on the military characteristics. These characteristics had been prepared especially for the SERGEANT warhead, but it was felt that the size, shape and weight of the warhead should be optimized for other possible applications.[22]

(b)(3)

Since the missile system would not arm the warhead until the missile had entered the intended target area, there appeared to be no portion of the trajectory during which the proposed self-destruct system would be useful, and it was suggested that this requirement be deleted.

The option of air burst with contact preclusion was unclear, as both fuze and warhead attributes were involved, and contact-burst preclusion could be accomplished by the fuze. Since the warhead contained no energy source, it would be electrically inert and could be protected against accidental inputs by a handling safety device. This device would interrupt the power line from the adaption kit to the warhead and thus should be part of the Army's adaption kit. The warhead would have inaccessible trajectory-sensing devices, such as integrating accelerometers, and it was felt that caps that could be locked would provide no more safety than the use of caps having safety seals.[23]

(b)(1), (b)(3)

The higher yield weapon would have a maximum length of 65 inches and weigh not over 1200 pounds.[24]

Field Command notified Sandia January 9, 1961 that Report SC4445(WD), Proposed Ordnance Characteristics for the XW-52-X1 Warhead, had been reviewed in coordination with representatives of the interested Services. This review established that the design met all requirements of the military characteristics, with two exceptions. There was no provision for integral shielding against neutron radiation, but this had been accepted by the Army. Capability of monitoring the safe condition of the environmental sensing device would depend on current negotiations with the Army. The report had been accepted by the Design Review and Acceptance Group and was subsequently forwarded to the Division of Military Application.[32,33]

(b)(1), (b)(3)

The first XW-52-X1 Warhead tested was flown at the White Sands Missile Range March 10, 1961. The trajectory was low and the impact point about a kilometer short of the intended target.[35] Following this, three successful flights were staged in May 1961, and the balance of two flights was delayed pending availability of missiles.[36] These two flights were held in October 1961 and were successful.[37,38]

Static and centrifuge tests had meanwhile shown that the warhead design was more than adequate, and structural evaluation noted that the design could successfully withstand all handling and transportation loads, as well as carriage in the SERGEANT missile.[39] Engineering release of the Mk 52 Mod 1/SERGEANT was accomplished June 1961 on schedule, and early production achieved May 1962.

The Mk 52 Mod 2 Warhead was released January 28, 1963. This differed from the Mk 52 Mod 1 in that it incorporated a prescribed-action-link device, and entered production in February 1963.[40]

Sandia forwarded SC4715(WD), Final Report for the Mk 52 Mod 1 Warhead, to the Division of Military Application March 5, 1963. The report had been presented to and accepted by the Design Review and Acceptance Group. The warhead diameter was 24 inches, length 56.72 inches, and weight 925 pounds.

(b)(1), (b)(3)

RS 3434/34

History of the Mk 53 Weapon

(b)(1), (b)(3)

This device pointed the way to development of the Mk 53.

(b)(3)

Subsequently, the Division of Military Application wrote to Albuquerque Operations Office, September 2, 1958, requesting that preliminary arrangements be made, but stating that full authorization would not be released until the military characteristics had been issued by the Department of Defense.[4] An estimated operational availability date was requested.[5]

The Los Alamos Scientific Laboratory and Sandia submitted a tentative development schedule October 15, 1958.

(b)(1), (b)(3)

Los Alamos and Sandia held a joint meeting November 13, 1958. The bomb would be carried in B-47 and B-52 aircraft, with possible application to the B-58 Pod and perhaps even to the B-70. However, the high speed of the B-70 would create high bomb-bay temperatures, and it was felt that this might seriously affect such items

as the parachute and the high explosive used in the design.[7] Various cooling methods were considered, including insulation of bomb-bay walls, use of a jettisonable water jacket, or filling the bomb bay with a low-density material blown in after the weapon had been loaded in the strike aircraft. It was noted that the bomb dimensions were limited by the size of the B-47 bomb bay and that redesign or repackaging of some weapon components might be necessary.[8]

(b)(3)

Sandia studied several possible ways of stabilizing the bomb in flight. Fin deployment appeared necessary for a number of reasons. There was an adverse center-of-gravity location, and the aircraft bomb bay limited the fin height. Aerodynamic requirements required stabilization of the bomb shortly after release, and it was felt that a large fin area would be needed. It would be necessary to provide mechanical devices between the fins to make sure that all four fins deployed simultaneously.[10]

(b)(1), (b)(3)

Sandia forwarded the TX-53 development program definition to Albuquerque Operations Office June 17, 1959.

(b)(1), (b)(3)

Delivery methods for the B-58 Two-Component Pod, recently redesignated the BLU-2/B Pod, would include high-altitude free fall and possibly low-level pop-up. Use of the bomb less parachute container and fins as a laydown device in an MB-1-type Pod would also be considered.

The Department of Defense would provide a parachute, and the Atomic Energy Commission would be responsible for nuclear design and the rest of the bomb. Units furnished for the B-58 Pod application would contain complete fuzing and firing systems, with the exception of pressure-sensing and contact-fuzing devices supplied by the Air Force. Sandia would provide the engineering and production specifications for all other fuzing components and materials.

The program schedule would depend on successful development of materials for mitigating high shock, high-strength light materials for secondary nuclear component support, and high-strength aluminum for the weapon case. The aerodynamic shape would have extendible fins to provide proper stability of free-fall bombs released at high altitudes.

The B-70 bomb application would be sufficiently unique to require a field modification kit to provide the required aerodynamic and heat-resistant qualities. This kit would be design released after compatibility had been proven in flights and drops from B-70 aircraft, but it was predicted that such aircraft would not be available until about mid-1962.

(b)(1), (b)(3)

(b)(1), (b)(3)

Since the deformation switch used to produce contact firing signals in the complete bomb was different than the corresponding components in the Pod application, a connector was provided on the weapon skin to allow either type of deformation switch to be used.

(b)(1), (b)(3)

On July 15, 1959, the Air Force proposed that Sandia be responsible for providing pressure-sensing and contact-fuzing devices, rather than the Military, and this proposal was subsequently accepted by the Military Liaison Committee.[19]

An amendment to the military characteristics was issued August 4, 1959.

(b)(1), (b)(3)

A ballistic drop test was held September 12, 1959, and indicated need for modification of the low-level deployment sequence.

(b)(1), (b)(3)

The Air Force Special Weapons Center had requested a list of changes that would have to be made to provide a fuzing and firing system compatible with the low-level Special Weapons Emergency Separation System.

(b)(1), (b)(3)

Field Command wrote to the Air Force Special Weapons Center October 5, 1959, proposing that the variable timer for the laydown option be replaced with a single fixed time delay. This change would provide increased reliabiltiy and safety by eliminating the setting mechanism and the human effort involved in making the setting, and environmental protection would be increased, since the case would not have to provide a seal around the rotary shaft of the variable timer.[23] The Center replied October 16, 1959, noting that the Strategic Air Command had been queried, and a preference stated for the variable timer.[20]

Report SC4267(TR), Proposed Ordnance Characteristics of the Basic TX-53 and the TX-53 Bomb, was presented by Sandia to the October 21, 1959 meeting of the Special Weapons Development Board.[24] This noted that the Basic TX-53 would contain a

high-explosive implosion system, nuclear pit, gas-boosting system, secondary, electrical fuzing and firing system, primary case and Basic TX-53 case. The TX-53 Bomb would consist of the Basic TX-53, aft assembly with retardation parachute, extendible fins, shock-mitigating material, and nose assembly with impact switch.[3] The report was accepted and forwarded to the Division of Military Application December 4, 1959.[25]

Sandia had informed the Division of Military Application that the bomb would have to be thermally protected when carried in the B-70 aircraft, to maintain the bomb temperature below 165°F. This protection could be provided by bomb-bay cooling or insulation. Any modification to the bomb to provide the shock-mitigation system, afterbody or parachute with materials which could resist high temperatures would require at least 15 months of effort and would increase the weapon diameter to 52 inches, the length to 164 inches, and the weight to 9300 pounds.[26] Subsequently, December 10, 1959, the Air Force requested that any work toward establishing compatibility of the TX-53 Bomb with B-70 aircraft be halted, due to delays in the latter program.[19]

(b)(1), (b)(3)

Sandia informed the Air Force Special Weapons Center that the TX-53 Bomb experienced severe pitchdown in drop tests made from B-47 aircraft. This caused parachute deployment problems, imposed high aerodynamic loads on the bomb, and increased the

possibility of contact between bomb and aircraft during weapon releases. Separation from B-52 aircraft appeared satisfactory.[30]

The Center replied February 8, 1960, noting that the B-47 bomb bay had caused problems in the past, but that this had not prevented designers from achieving weapon compatibility without modifying the bomb bay. This latter work would require extensive aircraft modification and probably result in performance degradation. It was noted that there appeared to be close correlation between delivery speeds and weapon release characteristics. Since the B-52 was being modified to permit low-level flight at 400 knots, it was requested that separation tests of bomb from B-47 at this speed be conducted.[31]

Sandia notified Field Command February 16, 1960 that the design intent of the TX-53 was to ensure that fuzing-system restrictions on the bomb release altitude were less severe than limitations imposed by safe escape or other criteria. It was felt that, except for a minor altitude restriction for some retarded contact bursts, this design intent appeared to have been met. The fuzing system thus appeared to provide the necessary flexibility for the intended use of the bomb, and formal concurrence in the design was requested.[32] Field Command subsequently replied, noting that the Strategic Air Command stated that the release capabilities of the TX-53 Bomb were acceptable.[33]

Laydown tests demonstrated that the terminal velocity of the TX-53 Bomb was less than anticipated, and a change to the nose design was made which reduced the overall length of the bomb and provided better clearance in the B-47 bomb bay. It now became possible to jettison the parachute and its container in the free-fall option, and this change shifted the weapon center of gravity far enough forward so that aerodynamic stability was attained without deployable fins.[34]

A study of a warhead to be carried by the TITAN missile was reported March 13, 1960. This called for use of a high-yield warhead at ranges up to 5500 nautical miles, and a lighter weight warhead for targets 8500 miles distant. The XW-38 Warhead was being developed for application to the TITAN and ATLAS missiles for the latter usage, and consideration was given to the TX-53 design for the shorter

range, higher yield employment. The warhead could be severely reduced in weight over the bomb application, as the impact-mitigation system would not be needed.[35]

On May 17, 1960 the Director of Defense Research and Engineering requested the Atomic Energy Commission to participate in a feasibility study of warheads to be used with the TITAN II or SM-68B intercontinental ballistic missile system.

(b)(1), (b)(3)

The study report was published July 12, 1960, and recommended development of an XW-53 Warhead.

(b)(1), (b)(3)

The TITAN missile operational date was March 1963 and it was felt that the warhead could be provided at the same time. It was noted that if production authorization were received in the near future, flight tests could be started by November 1961, design release made in the same month, and early production achieved by December 1962.[37]

The Director of Defense Research and Engineering requested the Atomic Energy Commission, September 1, 1960, to proceed with development of the XW-53 Warhead, with the Air Force being designated cognizant agency for the Department of Defense, and normal Defense Atomic Support Agency participation.[38]

The military characteristics for the TITAN warhead were approved by the Military Liaison Committee October 18, 1960. Fuzing options included air burst with contact backup and contact burst.

(b)(1), (b)(3)

Sandia wrote to Albuquerque Operations Office March 10, 1961, discussing the development program definition for the XW-53. Sandia would be responsible for design and production specifications of the warhead, with the exception of explosive and nuclear parts. General Electric would develop the re-entry vehicle, and Glenn L. Martin Company would be in charge of missile development. Warhead design release would be in April 1962 with early production in January 1963.

per second. A disreefed 48-foot, three-parachute cluster replaced a 44-foot cluster.

The Air Force decided to provide the three 48-foot parachutes with a 22-1/2 foot reefing line and a 1-second reefing time. This resulted in an overload on the second parachute stage. To reduce this load and to move some of it to the first stage, the reefing-line length was increased to 25 feet. This design functioned satisfactorily, but the loads extrapolated to an overly high figure for the maximum drop conditions of the bomb. Sandia dropped a unit and found that two of the three parachutes failed completely by breaking the suspension lines.[41]

Sandia notified the Division of Military Application May 12, 1961, that the bomb production date would have to be delayed due to lack of a satisfactory retardation system. The Division of Military Application requested that another program assessment be made after drops scheduled for early June 1961.[42]

A meeting was held June 27, 1961 to discuss the results of the BLU-2/B drop-tower and laydown programs. There had been wide variation in test results, although drop conditions had been kept relatively constant. It appeared that the angle of impact significantly affected impact accelerations, and it was decided that the rest of the drop-tower program would be delayed until enough laydown tests had been completed to determine whether the drop-tower velocities were realistic.[43] Subsequently, Sandia reported, August 8, 1961, that 10 drop tests had been made of a half-scale beer-barrel nose. Results showed that the nose was capable of reducing the longitudinal impact acceleration to less than 100 g's.[44]

The Air Force Special Weapons Center notified Albuquerque Operations Office November 30, 1961, that the parachute was compatible with the TX-53 Bomb as carried in B-47 and B-52 aircraft.

(b)(1), (b)(3)

Field Command notified Sandia January 23, 1962, that Report SC4553(WD), Proposed Ordnance Characteristics for the XW-53 Warhead, had been reviewed in coordination with representatives of the interested Services. The review established that the design met all the requirements of the approved military characteristics, with certain exceptions.

The diameter of 40.5 inches over the mounting flange exceeded the 37.5 inches allowed by the military characteristics, but this was acceptable, as was the warhead length of 103.5 inches rather than the desired 102 inches. It was felt that considerable increase in safety could be realized if the environmental sensing device were upgraded to minimize the possibility of its being inadvertently operated or bypassed in a fire environment, and it was requested that efforts be directed toward such improvement.

(b)(1), (b)(3)

Otherwise, the design was acceptable to the Department of Defense.[46]

Sandia wrote to Albuquerque Operations Office January 31, 1962, noting that a proposed acceleration of the XW-53 Warhead design, with release in October 1962 rather than February 1963, would require issuance of information considered premature even for the later date. Deliveries of development hardware had been delayed and there were progressive slippages in the flight-test program. However, every attempt would be made to provide certified production material by the date requested and, if not, operative components would be made available.[47]

Field Command notified Sandia February 13, 1962, that Report SC4621(WD), Interim Development Report for the TX-53 Basic Assembly and TX-53 Bomb, had been reviewed in coordination with representatives of the interested Services. There were a few deviations from the military characteristics. There was no warhead entity as such, but the basic assembly included the warhead elements, as well as all fuzing and firing components except the impact-fuzing or deformation switch, and this deviation was acceptable.

(b)(1), (b)(3)

Effective length of the TX-53 was 148.75 inches to the rear automatic deployment cover, slightly more than desired, but this length was compatible with designated carriers and was acceptable. The weight was 8850 pounds, slightly more than specified, and this also was acceptable.

(b)(1), (b)(3)

This latter capability would be provided at a later date.

(b)(1), (b)(3)

Sandia subsequently notified Field Command May 10, 1962, that the Mk 53 had three power sources; aircraft monitor and control system, fast-rise thermal batteries, and main-fuzing-system thermal batteries. The electrical system of the bomb had been designed so that the firing-system circuits were physically separated from any circuits likely to receive power in the event of fire. It was thus felt that the bomb provided sufficient fire safety, but thermal fuses would be included in the fuzing-system selector control as an added safeguard.[49]

The Mk 53 Bomb and the Mk 53 Basic Assembly were design-released August 10, 1962. It was noted that the B-47 bomb-bay spoiler doors had to be retracted for both high- and low-altitude releases to prevent adverse bomb pitchdown at release.[50]

(b)(1), (b)(3)

switch had to be manually turned to the ARMED position (either retard or free fall) before takeoff, or a weapon dud would result. The fuzing-system control selector provided choice of air or contact burst. Laydown delayed burst was automatically selected when the bomb was released below its specified altitude, with the aircraft monitor and control selector placed at AIR or GROUND.

When the bomb was released from the carrying aircraft, pullout rods were extracted, and this action activated pulse generators which initiated fast-rise thermal batteries and a set of sequential timers. The batteries supplied power to baroswitch and timers, and activated another set of thermal batteries.

(b)(1), (b)(3)

About one second after weapon release, sequential-timer contacts closed and completed circuits between battery pack and detonators in the automatic parachute deployment system. At the same time, the timer provided a signal that severed the retardation-parachute suspension lines, and the following deployment sequence occurred: The automatic deployment cover was separated from the rear case section by the explosion of a length of mild detonating fuse, the cover deployed a 4-foot-diameter pilot chute, the pilot chute deployed a 16.5-foot ribbon retardation chute permanently reefed to 12 feet, and the retardation chute deployed the laydown parachute system, which consisted of three 48-foot ribbon chutes, each reefed to 22.5 feet for 2 seconds after line stretch.

The laydown parachute system was designed to reduce the rate of fall of the bomb to less than 55 feet per second, and to position the bomb upright at the instant of impact. The energy of impact was absorbed by aluminum honeycomb in the bomb nose. Since strong surface winds might cause the bomb to fall over on its side, similar shock-absorbing material was placed around the bomb components.

As the rotary switch remained in the laydown option in low-altitude releases, main battery power was supplied to the laydown bus after bomb release. Retardation created by the laydown parachute caused an interval timer to operate toward its armed position, applying main battery power to the motor and contacts of the sequential timer.

(b)(1), (b)(3)

At detonation time a third switch closed, activating explosive switches and triggering the spark gap to cause bomb detonation.

(b)(1), (b)(3)

Less than one second after bomb release, the rotary switch turned to the high-level option position. Shortly afterward, the sequential timer completed a circuit between battery pack and detonators in the automatic parachute deployment system. If free-fall option had been selected, closure of contacts in the sequential timer applied power from fast-rise thermal batteries to parachute deployment system and severed the chute attachments, allowing the retardation chute to extract and discard the laydown parachute in its stowage can. If the retarded option had been selected, the sequence was similar to that for free fall, except that the parachute deployment proceeded normally.

Air-burst option could be selected by the aircraft monitor and control system.

(b)(3)

(b)(1), (b)(3)

Less than 1 second after weapon release, the option switch operated to the high-altitude option. Closure of a timer 1 second after release had no effect on Pod operation.

(b)(3)

If contact option had been selected on the Warhead Control Selector Switch before release, the fire baro was bypassed and the Pod contact crush switch was brought into the circuit. The firing pulse transformer circuit was completed by the impact crush switch which closed on impact with the target.[60]

(b)(1), (b)(3)

Report SC-WD-64-574, Final Development Report for the Mk 53 Mod 0 Warhead, was issued by Sandia in December 1965. This noted that the warhead system used a rotary chopper/converter system to change low-voltage direct current at about 28 volts to about 2100 volts direct current. An environment similar to the launch acceleration of the TITAN II missile had to be experienced to complete the converter arming circuit. This acceleration operated the environmental sensing device.

When two independent arming signals were applied to both chopper and converter, the applied voltage was chopped, transformed, rectified and used to charge the X-unit capacitor bank and arm the trigger circuit.

(b)(3)

Detonation of an armed warhead could be accomplished by either a low-voltage (17 volts) or high-voltage (250 volts) method. The output of the trigger circuit was applied to one probe of the dual-probe spark gap. This signal caused ionization of the spark gap, and energy stored in the X-unit capacitor bank was transferred to the detonators, causing detonation of the warhead. Energy from the capacitor bank also triggered an explosive timer on the neutron generators. This timer burned down and detonated the explosive driver which depoled a ceramic crystal. The crystal then supplied a high-voltage pulse to a deuterium-tritium tube which provided neutrons for initiation.[62]

History of the Mk 52 Warhead

The Mk 52 resulted from the effort to provide the Army SERGEANT rocket with an appropriate nuclear warhead. An early meeting was held September 25, 1953, with representatives of the missile contractor (the Jet Propulsion Laboratory of the California Institute of Technology), the Armed Forces Special Weapons Project and Sandia in attendance. It was noted that the SERGEANT would be 30 inches in diameter, 35 feet long, weigh 10,000 pounds, and be able to carry a 1500-pound warhead to a range of 75 to 100 miles. The SERGEANT was a surface-to-surface, solid-propellant guided rocket, intended as a replacement for the CORPORAL, which carried a Mk 7 Warhead.[1]

The Division of Military Application, in a letter dated November 27, 1953, noted that the SERGEANT had not yet been approved as an atomic weapon carrier, and that Sandia participation should be limited to liaison and interchange of information to assist the Jet Propulsion Laboratory in preparing a system proposal.[2]

Little immediate warhead work was performed, but by late May 1955 Sandia studies indicated that it would be possible to provide a warhead to meet missile requirements of reliability, simplicity, ease of operation, freedom from countermeasures, ruggedness and safety. A thermonuclear design was suggested, since the higher yield and efficiency of such weapon would have size and weight advantages that would aid in achieving missile objectives.[3]

The Assistant Secretary of Defense notified the United States Atomic Energy Commission August 29, 1955 that early production of the SERGEANT missile was scheduled for May 1959. Request was made for participation in a joint feasibility study of suitable warheads for the system, in cooperation with the Army and the Armed Forces Special Weapons Project, and this request was subsequently forwarded to both Santa Fe and San Francisco Operations Offices.[4]

By mid-April 1956, two successful SERGEANT flight tests had taken place. The rocket was inertially guided, and continuous guidance correction during the missile flight

was provided. The range was controlled by extending the drag brakes of the missile for a specified length of time.

(b)(1), (b)(3)

The Army's Picatinny Arsenal had been studying possible fuzing systems and proposed that a radiating-type fuze be used, with options of air burst with contact backup, ground burst, and air burst with contact preclusion. It was felt that either inertial or barometric fuzing would not be sufficiently precise, as it was hoped to develop a burst-height accuracy of ±50 feet.

(b)(3)

A feasibility study group had meanwhile been formed, with representatives from Field Command, Picatinny Arsenal and Sandia. This group reported, July 25, 1956, that it would be about a year and a half before firm atomic-warhead information would be required for the SERGEANT program, and that consideration of warhead designs was premature. It was proposed that warhead selection, as well as completion of the feasibility study, be deferred until after the 1957 nuclear test series.[6]

Picatinny Arsenal requested information on the one-point-detonation characteristics of the nuclear design, so that an adequate safing system could be devised.

(b)(1), (b)(3)

Rocket design continued, with little work being done on the warhead. The feasibility study group again met December 3-4, 1957, and learned that the rocket operational availability date of mid-1962 might be shortened by almost a year.

(b)(1), (b)(3)

(b)(1), (b)(3)

Picatinny Arsenal released the feasibility study report December 31. 1957.

(b)(1), (b)(3)

Typical targets were fighter airfields, command posts, headquarters, communication centers, supply and logistic installations, troop units, tanks and artillery.

The rocket was 31 inches in diameter, 31 feet long, and weighed 10,000 pounds at launch. It was composed of four major sections; propulsion, fins, guidance and warhead. The solid-propellant motor had a burning time of 28 seconds and reached a peak longitudinal acceleration of about 10 g's at burnout. The range was controlled by four simultaneously activated drag brakes which extended and retracted three times during the upward leg of the missile trajectory. The time that the brakes remained extended was determined by an internal computer which continuously compared the actual position and velocity of the rocket, as determined by an inertial platform, with the reference trajectory that the missile should be following for that particular range.

Time of flight varied between 120 and 200 seconds. About 22 seconds prior to impact, an arming decision was made, based on establishment of the square or window in space through which the missile would have to pass in order to receive an affirmative arming command. During the final 20 seconds of flight any necessary corrective maneuvers were performed.

The nose section for the warhead would have an overall length of 139 inches, with the base of the section having a diameter of 31 inches and tapering to a point. The warhead installation would be limited to a weight of 1500 pounds, of which 1250 pounds were allocated for the warhead. The warhead itself could have a maximum length of 65 inches.

(b)(1), (b)(3)

Warhead installation flights would start in April 1958, final systems demonstration of

(b)(1), (b)(3)

The Assistant Secretary of Defense notified the United States Atomic Energy Commission, October 10, 1958, that some time had passed since the Joint Chiefs of Staff had established a military requirement for a nuclear warhead for SERGEANT, but that a request for warhead development had been delayed pending a decision on the missile system itself.

(b)(1), (b)(2), (b)(3)

The Army would be the cognizant agent for the Department of Defense portion of the development, with normal Armed Forces Special Weapons Project participation.[13]

A Joint AEC/DOD Warhead Committee for SERGEANT was appointed and held its first meeting November 17, 1958. It was noted that the missile was in an advanced state of development and it appeared likely that the warhead flight-test program could proceed without major interruptions.

It was reported that considerable work had been accomplished on the missile fuzing system, but this had been designed to meet TX-43 requirements and might not be entirely applicable. There would be two options, air burst and contact burst, but no contact backup for the air-burst option. The fuze would be baro-armed and radar-fired in the air-burst option. Both impact crystals and crush switches would be considered for contact fuzing. At an altitude of 18,500 feet above the firing altitude, a baro offset switch would interrogate an arming-decision device to determine whether it was safe to arm the warhead. If trajectory and attitude were within limits, arming and firing signals would be generated in proper sequence.[14]

A SERGEANT meeting was held December 11-12, 1958. There was general agreement by all except Picatinny that a self-destruct feature was not desired. Development time scales were felt reasonable, with the exception of early flight-test dates which might be difficult to meet. The warhead would be design released in May 1960, with early production in May 1961, and would achieve operational capability in August 1961. Sandia proposed that a chopper-converter system be used. This would be a two-channel system, each channel of which would require a separate arming and charging signal. It was felt that a trajectory sensing or goof-proof device should be included, to provide ground handling safety.[15]

Sandia notified Albuquerque Operations Office, January 19, 1959, that it appeared entirely feasible to develop a warhead for the SERGEANT by August 1961, but that no firm commitment would be made until military characteristics had been received and evaluated.

(b)(1), (b)(3)

Military characteristics for the XW-52/SERGEANT were approved by the Military Liaison Committee January 20, 1959.

(b)(1), (b)(3)

Development authorization was released February 27, 1959.[18]

(b)(1), (b)(3)

Sandia forwarded the development program definition of the warhead to Albuquerque Operations Office April 22, 1959.

(b)(1), (b)(3)

Power would be supplied by the missile adaption kit. Sandia felt that the military characteristics required certain features that might limit use of the warhead for other applications or might compromise reliability, or were more appropriately adaption-kit requirements, and recommended changes were being discussed.[21]

Sandia wrote to the Division of Military Application April 29, 1959, commenting on the military characteristics. These characteristics had been prepared especially for the SERGEANT warhead, but it was felt that the size, shape and weight of the warhead should be optimized for other possible applications.[22]

(b)(3)

Since the missile system would not arm the warhead until the missile had entered the intended target area, there appeared to be no portion of the trajectory during which the proposed self-destruct system would be useful, and it was suggested that this requirement be deleted.

The option of air burst with contact preclusion was unclear, as both fuze and warhead attributes were involved, and contact-burst preclusion could be accomplished by the fuze. Since the warhead contained no energy source, it would be electrically inert and could be protected against accidental inputs by a handling safety device. This device would interrupt the power line from the adaption kit to the warhead and thus should be part of the Army's adaption kit. The warhead would have inaccessible trajectory-sensing devices, such as integrating accelerometers, and it was felt that caps that could be locked would provide no more safety than the use of caps having safety seals.[23]

(b)(1), (b)(3)

The higher yield weapon would have a maximum length of 65 inches and weigh not over 1200 pounds.[24]

Field Command notified Sandia January 9, 1961 that Report SC4445(WD), Proposed Ordnance Characteristics for the XW-52-X1 Warhead, had been reviewed in coordination with representatives of the interested Services. This review established that the design met all requirements of the military characteristics, with two exceptions. There was no provision for integral shielding against neutron radiation, but this had been accepted by the Army. Capability of monitoring the safe condition of the environmental sensing device would depend on current negotiations with the Army. The report had been accepted by the Design Review and Acceptance Group and was subsequently forwarded to the Division of Military Application.[32,33]

(b)(1), (b)(3)

The first XW-52-X1 Warhead tested was flown at the White Sands Missile Range March 10, 1961. The trajectory was low and the impact point about a kilometer short of the intended target.[35] Following this, three successful flights were staged in May 1961, and the balance of two flights was delayed pending availability of missiles.[36] These two flights were held in October 1961 and were successful.[37,38]

Static and centrifuge tests had meanwhile shown that the warhead design was more than adequate, and structural evaluation noted that the design could successfully withstand all handling and transportation loads, as well as carriage in the SERGEANT missile.[39] Engineering release of the Mk 52 Mod 1/SERGEANT was accomplished June 1961 on schedule, and early production achieved May 1962.

The Mk 52 Mod 2 Warhead was released January 28, 1963. This differed from the Mk 52 Mod 1 in that it incorporated a prescribed-action-link device, and entered production in February 1963.[40]

Sandia forwarded SC4715(WD), Final Report for the Mk 52 Mod 1 Warhead, to the Division of Military Application March 5, 1963. The report had been presented to and accepted by the Design Review and Acceptance Group. The warhead diameter was 24 inches, length 56.72 inches, and weight 925 pounds.

Albuquerque Operations Office

memorandum

DATE: January 3, 1994

REPLY TO ATTN OF: NESD

SUBJECT: Nuclear Explosive Safety Study Report

TO: RADM Charles J. Beers, Jr., USN, Deputy Assistant Secretary for Military Application, DP-20, HQ

This memorandum is for Defense Programs' approval and signature for the attached safety study report.

I have reviewed the safety study report, "Nuclear Explosive Safety Study of B53 Mechanical Disassembly Operations at the USDOE Pantex Plant."

I concur that the studied operations are not a threat to nuclear explosive safety and meet the Nuclear Explosive Safety Standards a., b., c., and e. and other nuclear explosive safety criteria of DOE Order 5610.11; except that portion which has not been implemented, as specified in Appendix A; and of AL Supplemental Directive 5610.11. The recommendations in this study should be approved and implemented. Nuclear Explosive Safety Standard d. is evaluated by the Department of Energy (DOE) Albuquerque Operations Office, Security and Nuclear Safeguards Division's security surveys and DOE Headquarters' inspections and evaluations of Pantex Plant security operations. These surveys and inspection and evaluations verify that there are positive measures to ensure adequate security of nuclear explosives pursuant to the DOE safeguards and security requirements. Accordingly, I consider that Standard d. is met for the Pantex Plant.

I recommend approval of the attached safety study report.

B53 Warhead Electrical System. The elements of the B53 electrical system associated with the bomb firing system are the lightning arrestor connector (LAC), the MC4065 power pack, the MC1199 electrical system safing switch, two MC4066 neutron generators, the MC744B X-unit, two MC1262 fast-rise thermal batteries, and two MC1264 thermal batteries. The B53 bomb arming and firing system is dual-channel except for the capacitor bank, and the spark gap.

The LAC provides the electrical interface to external sources of electrical energy and in conjunction with the MC2969 strong-link switch protects against electrical energy from a lightning strike. The LAC is located at the bomb/pullout cable interface.

The MC4065 power pack contains a high voltage transverter, a trigger circuit, the neutron generator low voltage attenuator, and the MC2969 strong-link switch which are potted in a stainless steel housing. The MC2969 is enabled by a unique signal provided by a source external to the bomb. The MC2969 interrupts all electrical lines, except electrical ground, going into the firing set.

The MC1199 electrical system safing switch is manually operated and provides visual indication of the switch position (safe, retard, or free-fall). The handle of the MC1199 is mechanically locked in the safe position by a solenoid-operated pin. The MC1199 may be operated to

the safe position with or without power applied to the solenoid.

DOE b(3) C

Two MC1262 fast-rise thermal battery packs are used in the B53. The MC1262 is a two-section thermal battery containing a 12-volt fast-rise section and 28-volt power section.

Two MC1264 thermal batteries are used in the B53 to provide dual channel power for the fuzing system. The MC1264 is nominally a 28-volt battery with an activated life in excess of 240 seconds. It is activated by electrical power from the 12-volt section of the MC1262.

Nuclear Explosive Safety Theme. Although the B53 was not developed with modern design criteria, several abnormal environment nuclear explosive safety design features have been added to enhance nuclear explosive safety. The nuclear explosive safety theme of the B53 involves energy diversion through conductive metal barriers, exclusion of electrical energy into the firing set by a strong-link switch that is enabled by a unique signal, and location of the strong-link near the weak-links. A LAC is used at the bomb/pullout cable interface to provide protection against electrical energy to the bomb that could result from lightning strikes.

DOE b(3) C

[redacted] Also, all B53s in stockpile are inherently one-point safe.

S Permissive Action Link (PAL). The B53 does not have a PAL capability.

S Command Disable (CD). The B53 does not have a CD function.

Non-DOE Components. All components of the B53 are DOE's responsibility.

DOE b(3) C

[redacted]

Shipping Configuration. The H794 Hand Truck is a caster-mounted metal truck used for shipping, storage, positioning, and maneuvering of the B53. The H794 is approximately 10 feet long and 5 feet wide and weighs approximately 1000 pounds. The bomb is held in place by two aluminum bands and longitudinal movement is resisted by a telescoping steel shear pin.

Tiedown Specification for On-Site and Off-Site Transportation of the B53

Tiedown requirements for movement of the B53 at the Pantex Plant and over-the-road were reviewed by the NESSG. Sandia National Laboratories (SNL) provides the tiedown patterns used for on-site movement of nuclear explosives at the Pantex Plant. Tiedown requirements for over-the-road are provided to Mason & Hanger-Silas Mason Co., Inc. (M&H), through the Technical Publications 45-51 series. Test data and/or analysis used by SNL to determine tiedown patterns and tiedown materials used in the tiedown of B53 are available at Organization 9613, SNL, New Mexico, have been reviewed, and meet the criteria established in Reference B for on-site transportation and Reference E for over-the-road transportation.

Chemical Compatibility

The materials compatibility program conducted tests to ascertain continued safety of all nuclear explosives when subjected to chemical interactions between materials or chemical aging throughout the stockpile life. No increased safety risks due to chemical compatibility problems have been identified. Also, the explosive compatibility program shows that there are no incompatibilities with the materials and surroundings found at the Pantex Plant and the B53 HE.

HE Aging

Selected properties of Cyclotol and Composition B have been evaluated from aged stockpile materials and local testing. There are no signs of degradation from aging or incompatibility.

One-Point and Criticality Safety

Los Alamos National Laboratory (LANL) certifies that all B53s remaining in stockpile have been individually calculated to be inherently one-point safe.

S DOE 6(3)

[redacted]

LANL also certifies criticality safety, even in abnormal environments, provided only that the primary remains intact. Also, for as many as 10 undamaged B53s, there are no criticality concerns for any spacing/arrangement.

Response to Pantex Plant Abnormal Environments

Appendix B provides information about and the response of the B53 in configurations C and D to the identified and defined abnormal-environment threats at the Pantex Plant. The nuclear explosive safety design features of the B53, the Pantex Plant facilities where the B53 will be processed, and nuclear explosive safety controls and procedures in effect at the Pantex Plant combine to result in a predictably-safe response (no worse than a one-point detonation) to all identified and defined single and multiple abnormal-environment threats at the Pantex Plant for each configuration of the B53, except for tornado. The NESSG believes that an aircraft crash could also result in an unpredictable response. An unpredictable response would require the bomb center case to be breached, a compromised firing set, an appropriate energy source, and an intact primary. It is highly unlikely that a force strong enough to breach the bomb center case would leave the main charge detonators, high explosive, and pit undamaged. Additionally, the appropriate energy would have to be applied to more than one detonator simultaneously since the B53 is inherently one-point safe. The protection provided in Zone 4 and Zone 12 structures of the Pantex Plant, the nuclear explosive safety controls and procedures in effect for all nuclear explosive operations, and the rugged construction of the hardened trailers significantly reduce the threat to nuclear explosive safety of the abnormal environments. The NESSG believes that the possibility of the tornado or aircraft crash resulting in a threat to nuclear explosive safety is remote.

Reader-Worker Procedures and Checkoff Lists

Reader-worker procedures and checkoff lists are required and in use for those B53 mechanical disassembly operations requiring person-to-person coverage.

Additional Information

Additional information about the B53 and about the operations associated with the B53 is in Appendices B, C, and D.

Issues Resolved Without a Finding

1. A PT4118 multicircuit continuity tester is used to verify the safe position of the MC2969 strong-link switch before disassembly of the nuclear

explosive. The NESSG proposed that this test be performed only once after bomb return and that the test be performed in the Zone 12 disassembly bay. This action was agreed to by M&H and SNL. It shall be implemented prior to resuming B53 disassembly operations and the applicable operating procedures shall be revised by M&H and verified by DOE/Amarillo Area Office (AAO).

2. M&H and SNL proposed delaying removal of the protective shroud over the detonator cables to reduce the vulnerability of the nuclear explosive and thus the requirements for person-to-person coverage. The NESSG agrees with this proposal. Removal of the protective shroud shall occur as late as possible in the disassembly process. This change shall be implemented prior to resuming B53 disassembly operations and the applicable operating procedures shall be revised by M&H and verified by DOE/AAO.

3. M&H proposed to stage the end cap assembly (primary) in Zone 12 prior to its disassembly operations. Staging will be accomplished in a new stand that is similar to the old stand, but with provision for a totally enclosing metal cover and protective blankets. The NESSG agrees with this proposal. After receipt of this tooling and before resumption of B53 disassembly operations, the tooling shall be reviewed by Battelle Pantex/Nuclear Explosive Safety Division (NESD) and DOE/AAO/Nuclear Explosive Safety and approved by DOE/AL/NESD. Prior to resuming B53 disassembly operations, the applicable operating procedures shall be revised by M&H and verified by DOE/AAO.

Conclusions

The NESSG concluded that References A through G are valid, appropriate, and adequate and are applicable to the studied B53 operations. The NESSG also concluded that the procedures, equipment, and administrative controls to be employed with the studied operations are not a threat to nuclear explosive safety and meet Nuclear Explosive Safety Standards a., b., c., and e. and other nuclear explosive safety criteria of DOE Order 5610.11; except that portion which has not been implemented, as specified in Appendix A; and of AL Supplemental Directive 5610.11. Nuclear Explosive Safety Standard d. is evaluated by the DOE/AL, SNSD's security surveys and DOE Headquarters' inspection and evaluations of Pantex Plant security operations.

B. DOE/AL Master Tester List (MTL)

Discussion

The following tester is needed for B53 disassembly operations at the Pantex Plant:

Tester	Category	On MTL for other Programs	Analysis in Appendix B and Reference	Needed for Operations
PT4118	Blue	Yes	---	Yes

The application of the above listed tester to the B53 was reviewed. Appendix B contains the tester safety analysis summary and tester/nuclear explosive interface analysis for the PT4118 tester.

> The PT4118 multicircuit continuity tester is a blue decal tester used on the B53 system to verify the safe position of the MC2969 strong-link switch. The PT4118 is a hand held tester using a light emitting diode (LED) to indicate the continuity of an external circuit. It derives its electrical power from an internal mechanical hand crank generator. Two independent circuits can be checked at the same time. The PT4118 contains a mechanical voltage source, dual current limiters, dual voltage limiters, and two LED current monitors to indicate an external circuit continuity for two independent circuits. The external circuit is connected in series with the voltage source, current limiters, and LED. Continuity is indicated for circuits less than 4000 ohms. The PT4118 does not contain any stored energy sources (e.g., a battery). Lab testing of the PT4118 has revealed output currents of 0.5 to 0.75 amperes through an external load of 5 ohms. This is in the form of 100 nanosecond wide pulses randomly generated during operation of the hand crank generator. This technically violates the blue decal limit of 0.1 ampere. No critical circuit hazard exists because the energy deposition resulting from the 100 nanosecond current excursions is below the no-fire level of all electro-explosive devices within the nuclear explosive stockpile.

Conclusions

The NESSG concluded that the deviations from accepted design criteria by the PT4118 tester are of no consequence. The PT4118 tester is not a threat to

nuclear explosive safety when employed in the intended application for tests on the B53.

Recommendation AL MTL

The PT4118 be listed on the AL MTL for the B53.

Action

AL

C. Safety Rules and Immediate-Action Procedures

Discussion

The NESSG evaluated the proposed specific Safety Rule and immediate-action procedures to be used for B53 operations.

Conclusions

The proposed specific Safety Rule adequately covers B53 disassembly operations.

Specific immediate-action procedures (not All Other Programs) are required for B53 disassembly operations.

Recommendations - Safety Rules and Immediate-Action Procedures

1. Approve the B53 specific Safety Rule as follows:

   Upon bomb return, before disassembly operations are performed, the MC2969 strong-link switch shall be electrically monitored to verify the safe condition of the switch.

2. Approve the immediate-action procedures for the B53 as follows:

   a. No attempt should be made to move the nuclear explosive.

   b. Turn off and disconnect all test equipment from the nuclear explosive.

   c. Further operations (including disassembly) on the nuclear explosive are specifically prohibited.

APPENDIX A

DOE ORDER 5610.11 IMPLEMENTATION

There is a portion of DOE Order 5610.11 which has not been implemented and which is applicable to the "Nuclear Explosive Safety Study of B53 Mechanical Disassembly Operations at the USDOE Pantex Plant," dated October 1, 1993. This portion is applicable to the Department of Energy Albuquerque Operations Office.

Chapter IX; Risk Assessment. This chapter requires quantitative risk assessments for all onsite operations. The risk assessment program is being implemented; however, the risk assessment for the B53 has not been started at this time.

I. SCOPE

The scope of this Nuclear Explosive Safety Study is limited to those operations performed during B53-1 disassembly for removal of parent unit parts to be used during Joint Test Assembly build. These operations include on and off-site transportation of the B53-1, disassembly of the B53-1 through removal of the firing set (power pack and X-unit) from the aft cap, reconstitution of the remaining material into a BA53-like assembly, and on-site transportation of the BA53 to storage. Specifically excluded from this study is disassembly of the nuclear system.

II. DESCRIPTIONS

A. General Description of Bomb

The B53-1 is a thermonuclear device, approximately 148 inches long and 50 inches in diameter weighing approximately 8850 pounds. It consists of a nuclear system and electrical system components. The bomb provides only a laydown option and is timer armed and fired. The bomb consists of a Basic Assembly (BA) and Basic Shape Components. A view of the shape components exploded away from the Basic Assembly BA is shown in Figure 1. The BA contains the nuclear system and the electrical component assembly.

C

DOE b(3) C

DOE b(3) C

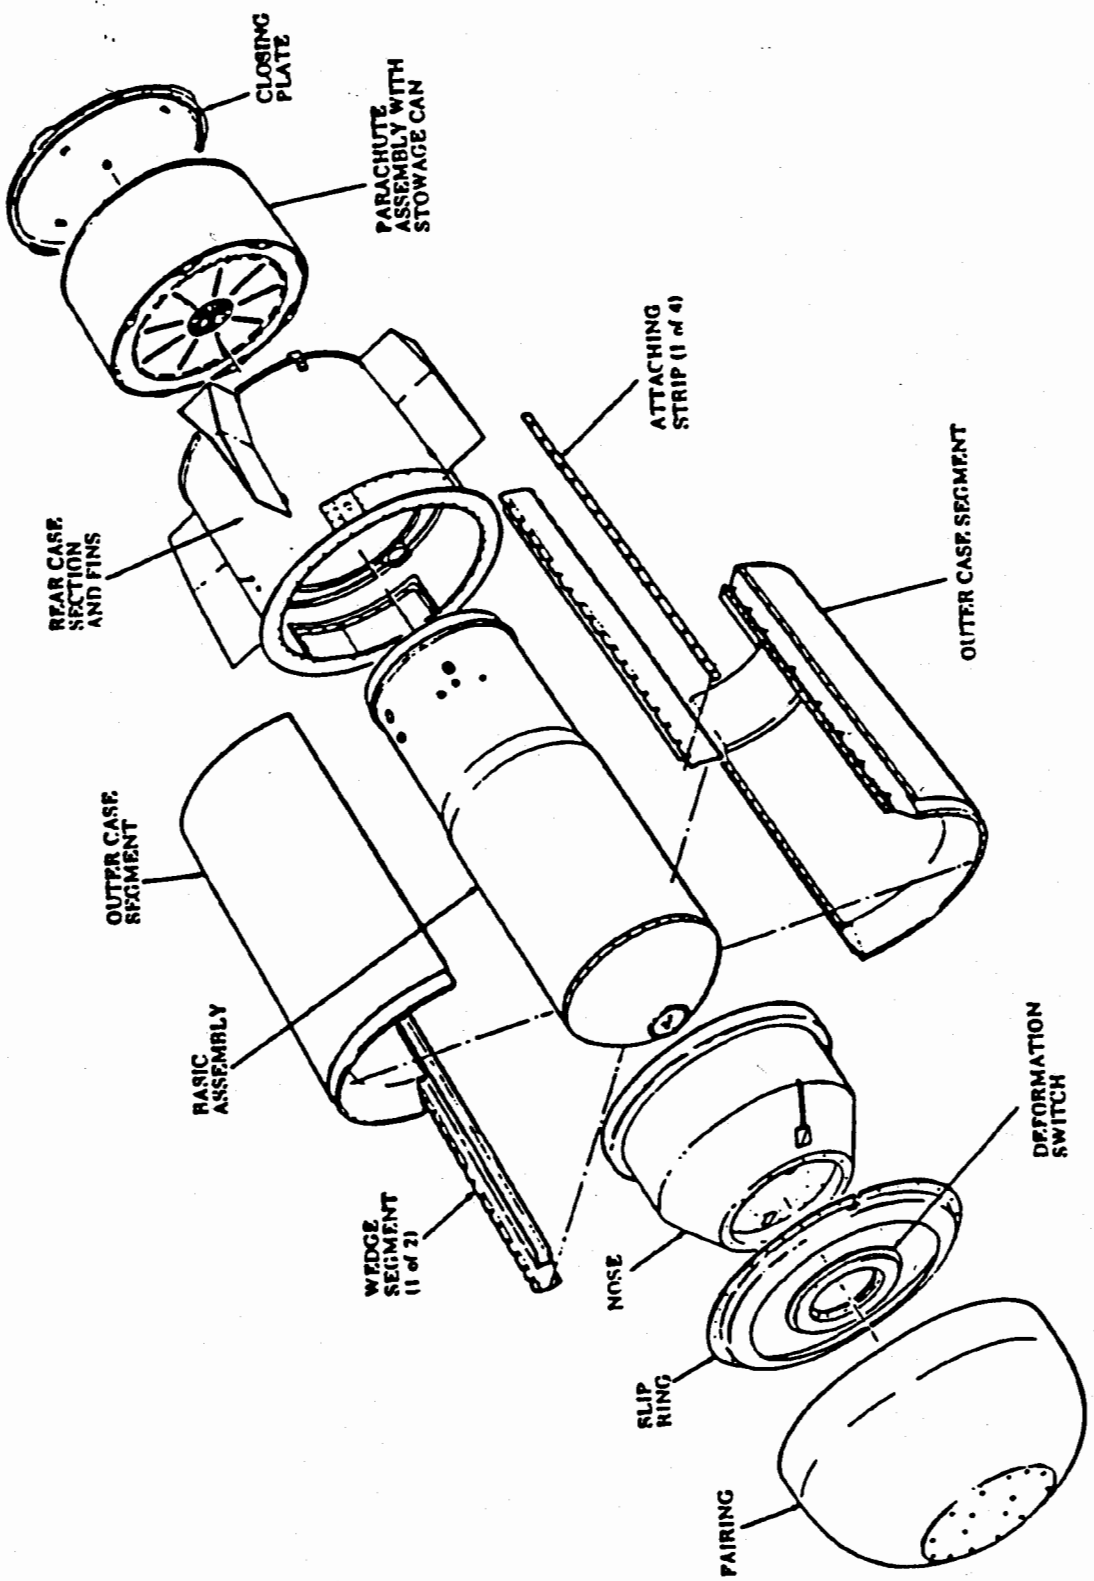
The case of the BA is an aluminum structure that consists of two 1/2-inch thick cylindrical sections, a 1/2-inch thick conical section, two end caps, and a closure plate. The complete fuzing and firing electrical component assembly is contained in the BA between the aft end cap and the closure plate.

B. Nuclear Warhead Electrical System

DOE b(3)

C

MC1178 Laydown Timer -- The MC1178 includes two electric motors (SA377) for operation of two separate channels. Each motor operates two SA833 snap-action switches at each of three time intervals. The switches are wired so that fuzing channels are switched by either timer motor. Fire signal times from 30 to 240 seconds, in 30-second increments, can be set into the MC1178 with a



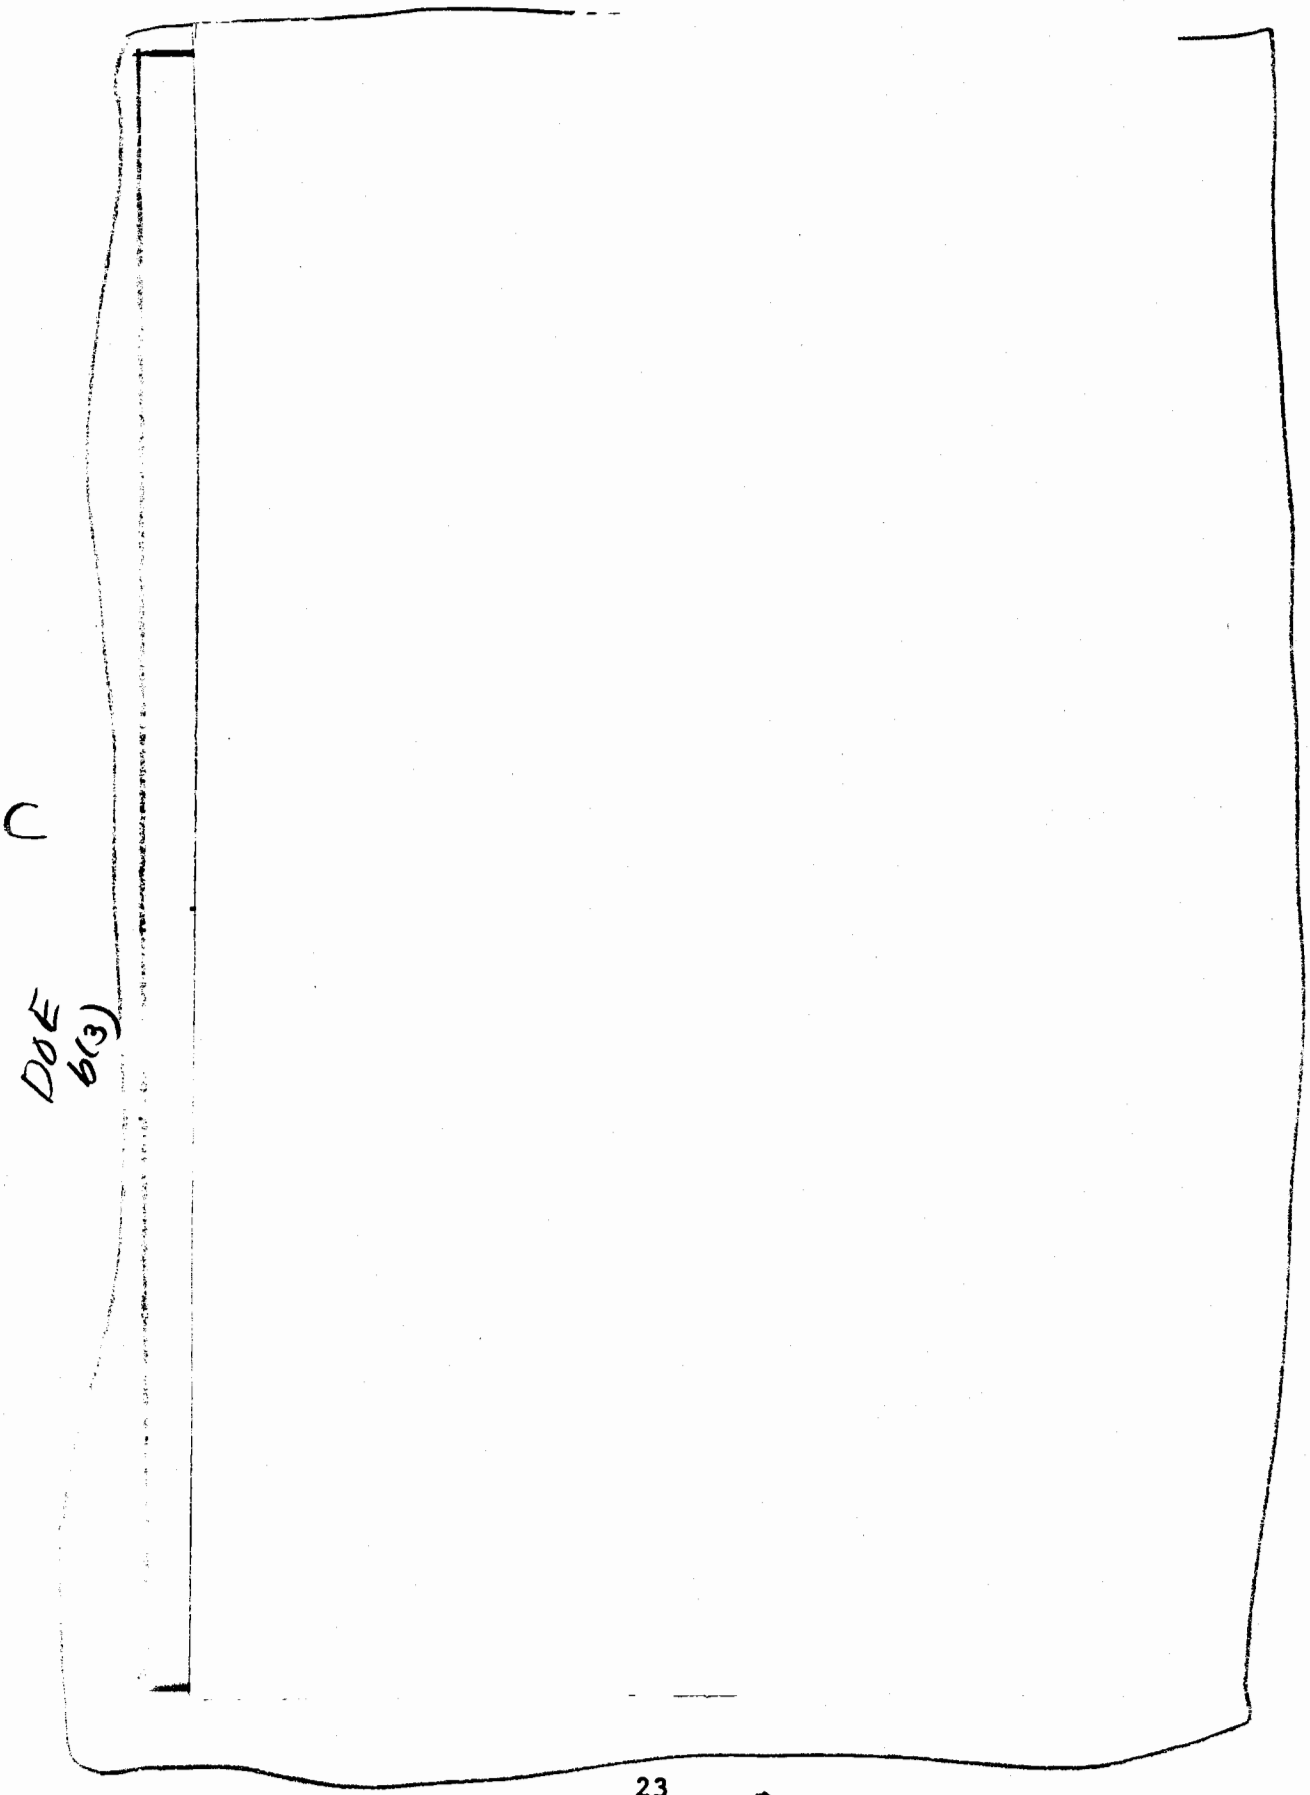


Figure 1 - B53-1 Bomb Exploded View

DOE
b(3)

DOE
b(3)

C

screwdriver. The setting on the timer indicates the time from extracton of the pullout rods and detonation.

MC1199 Electrical System Safing Switch -- The MC1199 is manually operated external to the weapon and provides visual indication of safe or unsafe conditions during ground handling. It has three control positions: safe, retard, and free-fall.

DOE b(3)

C

MC1204 Explosive Switch and Fuse Pack -- The MC1204 is a single package containing all of the explosive switches and electrical fuses used in the B53. It consists of four MC749 self-contained explosive switches, two SA1022 fuses, and four SA960 fuses.

MC1237 Interconnecting Box -- The MC1237 completes the circuits between the components in the main fuzing system. This interconnecting box contains no resistors but is similar in construction to the MC1203.

MC1262 Thermal Battery Packs -- Two MC1262 fast-rise thermal battery packs are used in the B53. The MC1262 is a two-section thermal battery containing a 12-volt fast-rise section and 28-volt power section. Basically, it is two batteries in a single case with a common negative terminal.

DOE b(3)

MC1264 Thermal Batteries -- Two MC1264 thermal batteries are used in the B53 to provide dual channel power for the fuzing system. The MC1264 is nominally a 28-volt battery with an activated life in excess of 240 seconds. It is activated by electrical power from the 12-volt section of the MC1262 to either of the two MC1210 electrical matches in the MC1264. The SA925 thermal monitor is incorporated into the MC1264 to provide means to determine activation status of the battery.

MC1268 Interval Timer -- The MC1268 includes two MC1269 mercury-thallium switches and two SA906 motor-driven timers.

DOE b(3)

MC4065 Power Pack -- The MC4065 contains a high voltage transverter, a trigger circuit, the neutron generator low voltage oscillator circuit and trigger attenuator, and an MC2969 Strong-Link Switch which are potted in a stainless steel housing.

DOE b(3)

MC4066 Neutron Generator -- Two MC4066 generators are used to provide external initiation of the nuclear system.

DOE b(3)

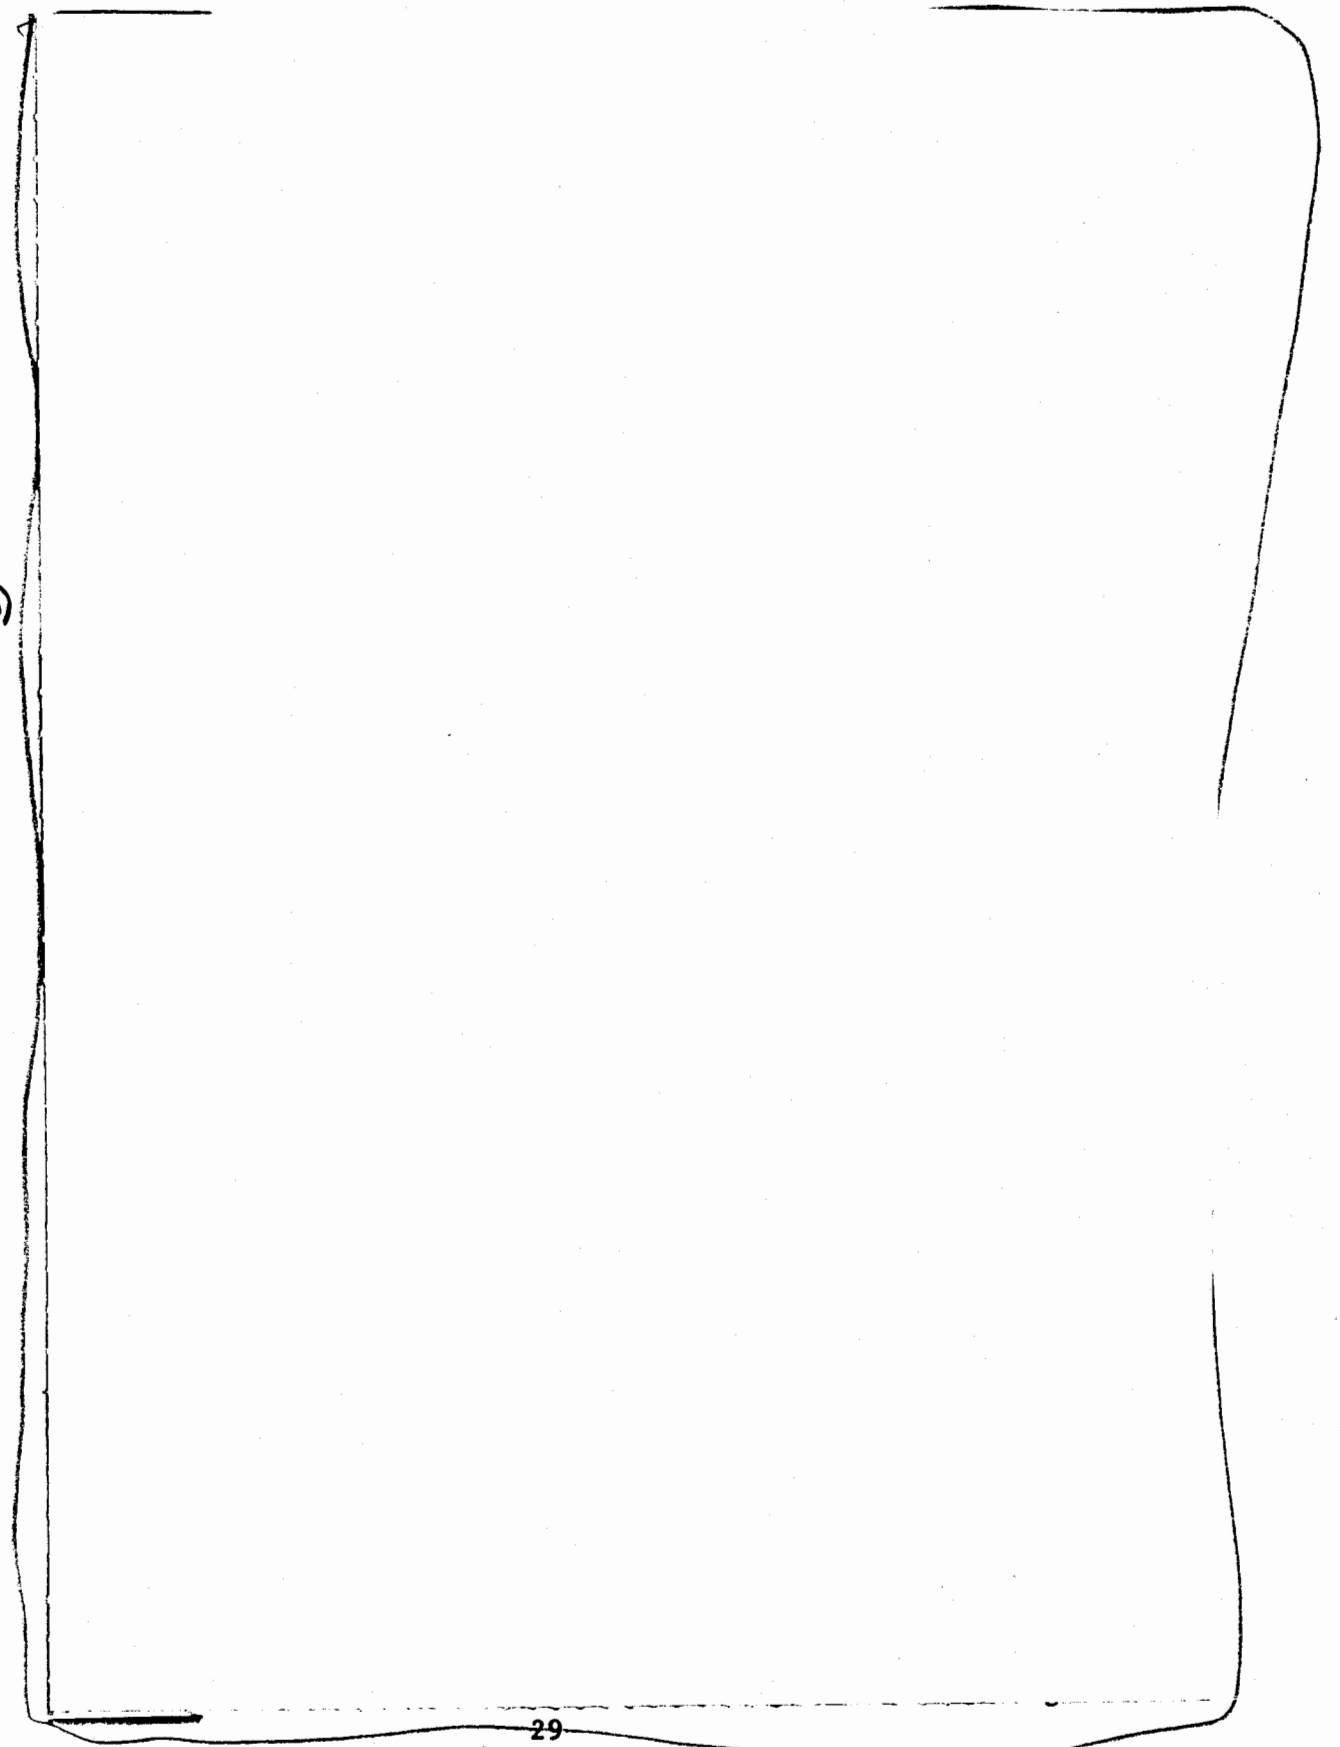
Parachute System – The parachute system includes three mild detonating fuze (MDF) systems, a 4-foot pilot chute, a 16.5-foot ribbon-type chute permanently reefed to 12 feet (retard chute), and three 48-foot ribbon-type chutes (laydown chutes), each reefed to 22.5 feet for 2 seconds after line stretch. Each parachute is packed into its deployment bag before assembly into a parachute stowage can.

The three MDF systems provide for parachute deployment, separation of the laydown extraction parachute, and release of the complete parachute system for high-altitude free-fall option (not available in B53-1).

The parachute stowage can is a honeycomb structure that provides a parachute volume of 26 cubic feet and contains two suspension line lug systems. One of the lug systems is used to attach the laydown chutes and to provide a load-carrying path to the rear case section. The other lug system is used to attach the retard chute. It contains a cutting anvil to be used, in conjunction with the MC1581 shaped charge mild detonating fuze system (flexible linear-shaped charge) in the rear case section, to cut the retard chute suspension lines in the laydown option. Thus, the retard chute deploys the laydown chute.

C. Nuclear Explosive Safety Theme

The safety theme of the B53-1 includes energy diversion through conductive metal barriers, protection of entry into the exclusion region by a strong-link switch that is enabled by a unique signal, and weak-link/strong-link collocation.



C
DOE b(3)

DOE b(3) S

- All remaining B53-1 pits in stockpile have been individually calculated to be inherently one-point safe.
- The design approach to provide isolation of critical circuits from sources of electrical energy in abnormal environments is to enclose those critical elements with an exclusion region. The entry of electrical energy into this region is through an MC2969 Strong-Link Switch that is enabled only by receipt of a unique signal. The unique signal is generated external to the bomb such that transmission of the unique signal indicates the intent to arm the B53-1.
- A Lightning Arrestor Connector is utilized at the bomb/pullout cable interface to provide protection against inputs to the bomb that could result from lightning strikes.

DOE b(3)
C

TABLE 1 - Component Explosive Content and Firing Characteristics

DOE b(3)

C

H. Shipping Configurations

Two shipping configurations exist during the activities addressed in this study. Both configurations utilize the H794 Hand Truck which is a caster-mounted metal truck used for shipping, storage, positioning and maneuvering of the B53 (see Figure 4). The H794 is approximately 10 feet long and 5 feet wide and weights approximately 1000 pounds. Pior to disassembly, the bomb is handled/transported and following disassembly, the basic assembly is handled/transported. When the bomb is being handled, the H795 Adapter Kit is used to adapt the B53 to the H794 (see Figure 5). The bomb is held in place by the two aluminum bands and longitudinal movement is resisted by a telescoping steel shear pin. When the BA53 is being handled, the H796 Adapter Kit is used to adapt the BA53 to the H794 (see Figure 6). The basic assembly is held in place by the two aluminum bands and longitudinal movement is resisted by a fixed steel shear pin. Figure 7 depicts the B53 installed in the H794/795.

I. Tie-down Specification

Figures 8 through 11 shows the over-the-road tiedowns and Figure 12 shows the on-site tiedowns. The on-site tiedowns for the B53 and BA53 are identical. The over-the-road configuration was successfully tested and the on-site configurations were evaluated and found satisfactory (Appendix A). These data are on file in Division 9613.

J. Permissive Action Link

S The B53-1 does not utilize a Permissive Action Link.

K. Command Disable

S The B53-1 does not have a Command Disable feature.

III. DESCRIPTION OF ELECTRICAL TEST EQUIPMENT

The only electrical test performed on the nuclear explosive is verification of the status of the MC2969 strong-link switch. A detailed analysis of the tester used is included in Appendix C.

PT4118 Multicircuit Continuity Tester

Description - A manually operated, multiple-purpose continuity test set used with the CB2297.

Tester Analysis Summary - Lab testing of the PT4118 has revealed output currents of 0.5 to 0.75 amperes through an external load of 5 ohms. This is in the form of 100 nanosecond wide pulses randomly generated during operation of the hand crank generator. This does violate the blue label limit of 0.1 ampere. The energy deposition by these 100 nanosecond.excursions is not sufficient to initiate the explosive devices within the B53-1.

Tester/Weapon Interface Analysis - No Critical Circuit Hazard exists because the energy deposition resulting from the 100 nanosecond high current excursions is below the no-fire level of all electro-explosive devices within the B53-1.

IV. RESPONSE TO PANTEX PLANT ABNORMAL ENVIRONMENTS

A. Configurations/Facilities

Reference 2 was used to determine which abnormal environments are relevant to this B53-1 study. Through interpretation of the reference, Facility Categories II, IV, VI, VII, and VIII (12-104 Bays, Zone 12 Interconnecting Ramps and Passageways, Staging Igloos, Transport Operations, and Loading Operations) represent the possible facilities and sites that the B53-1 will encounter. The B53-1 will be Configuration C (Cased HE/Pit assembly but short of UU package configuration) and Configuration D (UU package configuration).

1. Single Abnormal Environments

The single abnormal environment responses are provided in Table 2. The table combines the five facility categories (not all environments are applicable in each facility), and considers two versions of Configuration C (the Aft Cap Assembly removed from the BA53 and the BA53 less fuzing and firing components).

Table 2 - B53 Single Abnormal Environment Response

Abnormal Environment	Configuration C	Configuration D	Rationale
Thermal			
Fire	P	P	HE will burn, confinement can lead to one-point detonation; one-point safe. If firing set present, strong-link/weak-link collocation provides assurance that firing set will not initiate detonators.
Cold	P	P	No unsafe condition postulated.
Heat	P	P	No unsafe condition postulated unless temperature reaches HE reaction temperature.
Electrical			
AC & DC	P	P	Cannot initiate exploding bridgewire detonators. If firing set present, strong-link interrupts all lines into exclusion region. Exclusion region protected by steel barrier.
EMR	P	P	Cannot initiate exploding bridgewire detonators. If firing set present, strong-link interrupts all lines into exclusion region. Exclusion region protected by steel barrier.
LIEMP	P	P	UU package protected by LAC. No testers used during disassembly.
Static Charge	P	P	Cannot initiate exploding bridgewire detonators. If firing set present, strong-link interrupts all lines into exclusion region. Exclusion region protected by steel barrier.
Chemical			
Water	P	P	Criticality becomes an issue during extreme accidents involving water flooding inside the pit. Prompt recovery (i.e., few days or less) from a water environment precludes any credible criticality concerns. If uranium is in contact with water for more than a few days them some corrosion will have begun. [redacted] (C, DOE b(3))
Processing Chemicals	P	P	No unsafe condition postulated.
Mechanical			
Impact	P	P	If firing set installed, strong-link continues to provide electrical isolation. HE is susceptible to one-point detonation. One-point safe.
Puncture	P	P	Objects penetrating basic assembly, causing actuation of the thermal batteries and bypassing the strong-link without the same or similar objects disabling critical elements is vanishingly small. HE is susceptible to one-point detonation. One-point safe.
Blast	P	P	HE is susceptible to one-point detonation. One-point safe.
Fragments	P	P	Objects penetrating basic assembly, causing actuation of the thermal batteries and bypassing the strong-link without the same or similar objects disabling critical elements is vanishingly small. HE is susceptible to one-point detonation. One-point safe.

Key: P - Predictable response.

2. Multiple Abnormal Environments

The B53-1 has no assured level of nuclear safety in a broad range of multiple abnormal environments as summarized in Table 3. The table combines the five facility categories and two versions of Configuration C as discussed for the single abnormal environments.

V. RISK ASSESSMENT REPORT

Not applicable for the B53-1.

VI. SPECIFIC SAFETY RULES

The following Specific Safety Rules currently exist for the B53-1 Bomb:

a. Upon bomb return and before disassembly operations are performed, the MC2969 strong-link switch shall be electrically monitored to verify the safe condition of the switch.

b. The thermal batteries shall not be electrically disconnected from the electrical component assembly interconnecting box in the critical assembly area.

c. In the NEA, the cover shall not be removed from the J7 connector on the MC4065 power pack.

Rules "b" and "c" should be deleted. Rule "b" does not contribute to the nuclear safety of the B53-1. In fact, removal of the thermal batteries enhances nuclear safety. It is our understanding that rule "b" exists only for the purpose of providing administrative control of power sources in the NEA. Positive control of the batteries would be accomplished by removing them from the NEA and taking them to the JTA assembly staging area. Rule "c" is unnecessary because analysis has shown that the weapon cannot be functioned by applying power to the MC4065J7 telemetry connector.

VII. IMMEDIATE ACTION PROCEDURES

The current immediate action procedures are those that are specified for most weapon programs:

(1) No attempt should be made to move the nuclear explosive.

(2) Turn off and disconnect all test equipment from the nuclear explosive.

(3) Further operations (including disassembly) on the nuclear explosive are specifically prohibited.

(4) Immediately notify the responsible M&H-SM assembly engineer.

These procedures appear adequate.

VIII. QUALITY TESTS

The only quality test performed during disassembly of the B53-1 for application in the Joint Flight Test Program is atmosphere analysis which includes checking for the presence of Tritium.

XIV. APPENDICES

A. -- Analysis of MC4065-J7 Telemetry Connector

B. -- B53-1 Transportation Tiedowns

C. -- Tester Analysis

APPENDIX A

Analysis of MC4065-J7 Telemetry Connector

Sandia National Laboratories

Albuquerque, New Mexico 87185

date: August 2, 1993

to: J. S. Clabaugh, 5115

from: D. M. Pierce

subject: B53 Investigation of JTA Connector J7 Inputs

The MC4065 Power Pack for the B53 SIP has a JTA connector(J7) which is connected into the exclusion region. See enclosure 1. All pin connections have an isolation resistor except the ground return. The resistors are one (1) watt fixed wire wound construction. The failure mode, when over-power is to fuse open and stay open circuited. The following current/voltage/power would have to be applied to arm and fire the power pack X-unit or charge the output capacitor through the bleeder/divider network:

Function	Current-Amps	Voltage-Volts	Power-Watts
A1/B1	0.221	2,238	495
A2/B2-Peak	3.2	32,028	102,489
A2/B2-Steady State	0.225	2,318	502
A3/B3	0.032	330	10.5
TM Bleeder/ Divider	0.029	146,760	31.5

As can be seen from the above table, the one watt input resistors would burn open and the circuit would be unable to supply current for arming and firing functions.

If you have further questions please call me on extension 5-8317.

APPENDIX C

Tester Analysis

hand crank generator. The energy in these pulses is extremely small and is calculated to be 2.8 ergs. (An electro-explosive detonator normally requires tens of thousands of ergs to operate.)

WORST CASE FAILURE ANALYSIS

The PT4118 is housed in an aluminum enclosure which does provide complete mechanical protection. No internal failures due to crush could go unnoticed by the operator; (Use is not allowed if the enclosure has been crushed.)

Except for the LED assemblies and generator, all components are part of the printed wiring assembly (PWA) which encloses the output connector. The PWA is sandwiched between a phenolic insulator and an aluminum cover to prevent accidental bypass.

The failure of a single component will not result in a voltage greater than 36 volts or a current greater than 100 milliamperes through an external load. The following scenarios were analyzed:

(The presents of the high current pulses detected during lab testing are not part of the following analysis, but must be used when making a final determination of the tester's performance.)

COMPONENT	*FAILURE MODE*	*OUTPUT*	*NOTE*
CR1	OPEN	36 VOLTS	
CR2	OPEN	30 VOLTS	
R1	OPEN	0 VOLTS	1
R1	SHORTED	70 ma	2
R2	OPEN	0 VOLTS	1
R2	SHORTED	70 ma	2
DS1	OPEN	30 VOLTS	3
DS1	SHORTED	30 VOLTS	3
DS2	OPEN	30 VOLTS	3
DS2	SHORTED	30 VOLTS	3
D1	OPEN	0 VOLTS	1
D1	SHORTED	30V/.75V	4

Notes:

1. Open circuit, no output to external load.
2. Current level for dual circuit monitoring. 35 ma peak for single circuit.
3. LED will not function for that circuit. (A shorting plug is provided to ascertain LED performance prior and post test.)
4. With a counter clockwise turn on the generator, peak output is 30 volts. With a clockwise turn on the generator, peak output is 0.75 volts.

DG10001 COMPARISON

1. The PT4118 meets the appropriate requirements of DG10001 issue M for the following paragraphs:

   - 3.3 a; Is independent of the safety features within the NE and will operate safely for all normal and credible abnormal environments.

   - 3.3 b; The PT4118 design does meet the overall design requirements of the NE.

- 3.3 d; Will prevent catastrophic failure because of the incorporation safety features such as:. strong outer case, PWA protected from shorting
- 3.3 e; No high energy sources or AC power is used
- 3.3 f; The PT4118 is housed in a rugged aluminum enclosure providing sufficient protection against crush and the like.
- 3.3 g; No batteries are used.
- 3.3 h; Safe operation is independent of tester orientation.
- 3.4 a; An internal hand crank generator supplies power to the PT4118. Barriers are not provided around the generator because power is available only when a mechanical (rotating) force is applied by the operator. This would not be available to any extent during an abnormal environment such as a crush. Adding barriers would not raise the level of safety.
- 3.4 b; The location and insulation, and mounting of current limiters are clearly shown on the applicable drawing.
- 3.5 a; The complexity of the NET has been minimized
- 3.5 b; No capacitors or inductors, which could store energy, are used.
- 3.5 c; Dual current limiters are used but they are of the same type. The resistors used for current limiters are wire wound. The fail mode for this type of resistor is open which will result in an interruption of the flow of current to the load resulting in a safe condition.
- 3.5 d; The maximum current available during a single component failure will not exceed 100 ma with two circuits in use.
- 3.5 e; No positive feature is included on the tester to prevent current from flowing through interconnecting cables while they are being connected to or disconnected from the NE. Although, because the operator must provide a physical input to the hand crank generator, it would be physically impossible for the operator to do both, crank generator and operate a connector.
- 3.5 f; Interconnecting cable contains only wires to those circuits to be tested.
- 3.5 g; The connectors used on the tester and interconnecting cable provide positive mechanical locking features to prevent accidental disconnection.
- 3.5 h; Power is only available while the generator is receiving a mechanical input.
- 3.5 k; The circuits being evaluated in the NE are nonnative and therefore cannot provide an added voltage or current not provided by the tester.

2. The requirements in DG10001 issue M that PT4118 does not meet to the letter are met in other ways they are:

f. **Nuclear Explosive Tester Oversight Group (NETOG):** A Sandia group charged with the life cycle design stewardship of testers to be used with nuclear explosives.

g. **Tester Abnormal Environment:** An environment in which a tester experiences voltages, currents, energy, forces, etc., that are outside the range of acceptable, expected levels specified by the design or project group.

h. **Tester Catastrophic Failure:** A NET is said to undergo a catastrophic failure if a fault or faults occur for any reason that cause the tester's output(s) to exceed the normal output(s) as specified by the design or project group responsible for the NET. This may include (1) single faults that occur in one component and are non-propagating, or (2) multiple faults that occur in parallel due to a common cause, or (3) dependent failures due to propagation of a single fault.

2. DOCUMENTS.

a. **DOE Order 5610.11:** Program to Prevent Accidental of Unauthorized Nuclear Explosive Detonations

b. **EP401045:** Engineering Procedure, Definition of Computer Software Configuration Items

c. **EP401075:** Engineering Procedure, Electrical Testers For Use With Nuclear Explosives

i. **SAND88-2955:** Guidelines for Software Security, (SFRD)

3. SAFETY DESIGN CRITERIA.

3.1 Safety Design Theme. A NET must not present a threat to nuclear explosive safety. A NET shall have a nuclear explosive safety design theme that is easily analyzed. Designers should use a "maximum-consequence" evaluation methodology, i.e., the worst case consequences of credible abnormal environments considering the energy sources, circuit design and the physical configuration of the tester.

3.2 Goal. Components, devices and circuits associated with safety features should fail in a safe manner.

3.3 General. Nuclear Explosive Testers should meet the following.

a. The design of the tester shall be independent of the safety features within a nuclear explosive and the tester shall operate safely for all normal and credible abnormal environments.

b. Design and evaluation of the tester must consider the overall design of the nuclear explosive under consideration. The existence and location of energy storage devices in the nuclear explosive shall receive careful consideration.

c. The lowest values of current and voltage that will adequately perform the function shall be used.

d. A NET shall incorporate safety features that will prevent catastrophic failure.

e. A NET requiring high energy power supplies, or a power source from any AC grid should be electrically and physically separated from the portion of the tester that connects to the nuclear explosive, see Figures 1 and 2.

f. Barriers or compartments may be used to simplify the analysis of the NET.

g. NETs with non-removable batteries requiring recharging shall have an interlock preventing the equipment from connecting to the nuclear explosive during battery charging.

h. Safe operation of the NET shall be independent of tester orientation. Tilting or rotation of a tester while in operation will have predictably-safe results.

3.4 Isolation. Nuclear Explosive Testers should meet the following.

a. Power sources should be located in a compartment(s) separate from other circuitry so that breakdown, improper use, or catastrophic failure will not deliver unintended power to the nuclear explosive.

k. Consideration should be given to voltages and currents reflected back to the tester from the nuclear explosive due to unexpected loads or internal generators. Under these conditions the tester must not apply excessive voltage and/or current to the nuclear explosive.

4. OTHER DESIGN CONSIDERATIONS.

4.1 National Electric Code. A NET must conform to applicable provisions of the National Electrical Code.

4.2 Electrostatic Discharge (ESD). For purposes of ESD protection, a connection on the tester should be provided for proper bonding.

4.3 Grounding. A NET should be designed so that no external earth ground connection is required.

5. NUCLEAR EXPLOSIVE TESTER SOFTWARE.

5.1 Development. Software development for NETs shall use proper software engineering techniques. These techniques are described in a five volume document "Sandia Software Guidelines" (SAND85-2344 thru SAND85-2348). The software shall be documented as required by Sandia EP401045 "Definition of Computer Software Configuration Items."

5.2 Safety Critical Software. Software designated as critical by the NESC review (EP401075), shall meet the following criteria.

a. Nuclear Explosive Safety Critical software should be developed in accordance with "Guidelines for Software Security," SAND88-2955 (classified SFRD).

b. The NESC software platform shall be reviewed by the NETOG and approved by the Nuclear Safety Department in accordance with EP401075.

subject: B53-1 Safety Study

Ref: SRD Document; dtd 8/25/94; subject: Input to the B53-1 Nuclear Explosive Safety Study at the Pantex Plant (U)

Two areas which were addressed at the subject safety study were not included in the referenced document.

1. Pantex personnel presented a proposal to stage the Aft Cap assembly in Zone 12 until nuclear system disassembly is approved rather than reassembling the Aft Cap assembly into a Basic Assembly and storing the Basic Assembly in Zone 4. The proposal included staging the Aft Cap assembly in building 12-64 which was not addressed under abnormal environments in the reference. Building 12-64 is in the same category as building 12-104 (Category II) and the abnormal responses provided in the reference are unchanged.

2. Additional information on over-the-road tiedowns was provided at the study. This information consisted of data from actual testing. Figures 1 and 2 show the test setup and figure 3 shows that the weapon yielded rather than the H-gear. Table 1 is the load cell data obtained until unit failure.

I. APPLICATION AND GENERAL DESCRIPTION

The B53 was also fielded as a basic assembly (BA53Y1) for the B-58 pod application.

The bomb does not incorporate Insensitive High Explosive (IHE) or a Command Disablement system.[1]

The B53 physical characteristics are listed below:

Weight:	8890 lb
Length:	144.6 in.
Maximum Diameter:	50 in.

II. NUCLEAR SYSTEM DESCRIPTION

The "basic assembly" includes the nuclear system and the weapon electrical system (WES), designed by Sandia National Laboratories (SNL).

A cut-away of the B53 is shown in Figure 1. Hazardous materials contained in the physics package are listed in Table 1.

Fig. 1 - B53 Mod 1 Bomb

DOE h(3)

All WES and bomb components external to the nuclear system are the responsibility of SNL and will be covered in the SNL complimentary input document to this NESS.

Gas Boost System

The following is the reservoir "pressure" design and test criteria.

If a bomb is rejected and reservoir removal is desired, a procedure has been developed and approved by Los Alamos to crimp and cut the pit tube. A location on the pit tube allowing the use of two crimp tools is selected. The pit tube is crimped at two very close loactions, sealing both the pit and the reservoir from the atmosphere. The tube is cut

DOE
6(3)

between the crimps. The gas reservoir and its section of the pit tube, with the crimp tool still in place, can now be removed from the bomb.

One-Point Safety

All B53 nuclear systems remaining is stockpile are individually calculated to be inherently one-point safe.

DOE b(3)

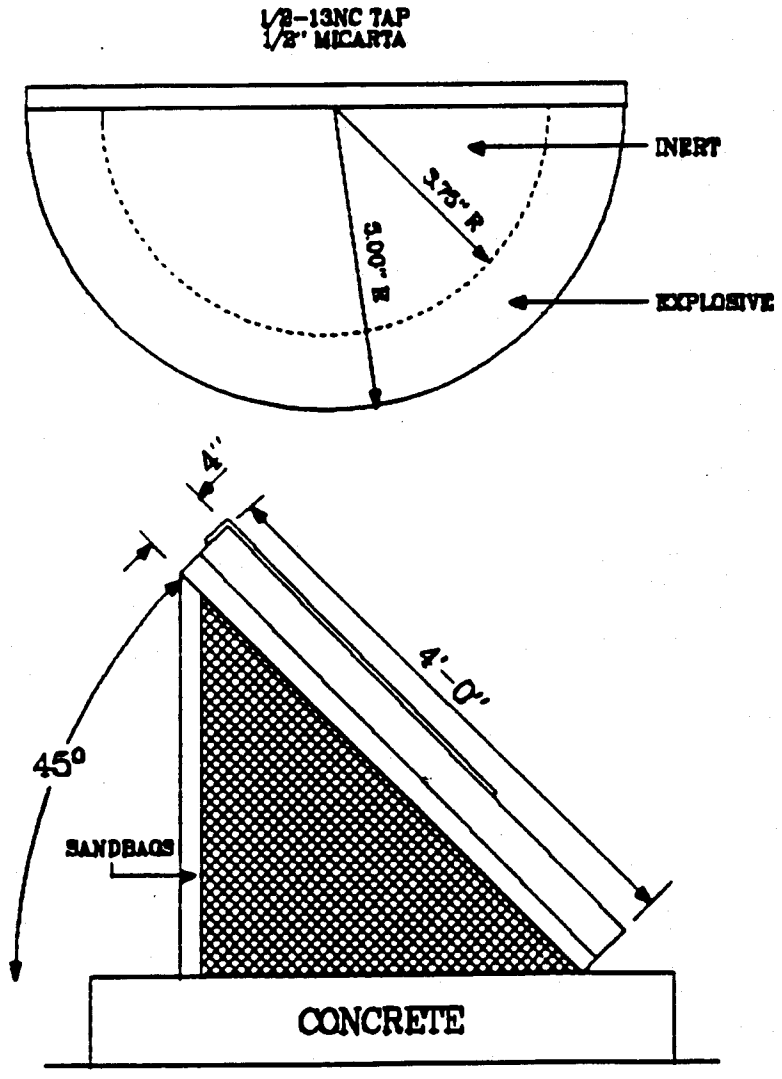
III. HIGH EXPLOSIVES SAFETY

Listed below in Table 2 are the high explosives used in the B53.

[redacted]

DOE 6(3)

PBX 9404 is a very energetic high explosive, and it is the standard by which most other HEs are compared. The figures and tables below provide a relative comparison of the sensitivity of the main HE charges in the B53 to other more modern high explosives used in later Los Alamos weapons.



The Skid test, illustrated in Fig. 5 and data Table 3, relates primarily to handling safety during fabrication and assembly of bare main charge HE parts. In this test, a hemispherical billet of HE is dropped vertically onto a sanded steel target inclined at 45°. The height at which events are obtained 50% of the time (H_{50}) is reported. This test combines impact and friction such as one might find in a handling accident and generally gives a relative rating of in-process high explosives.

The large scale pin drop or Spigot test (Fig. 6) is used to assess the safety of large HE charges subjected to combined mechanical impact and shearing. The test assembly is shown in Fig. 7. As above, H_{50} is reported. The Spigot test data (Table 4) are normally applicable to full warhead assemblies subjected to impacts and deformation.

Table 4 - Spigot Test Data Table

The data show that the Cyclotol/Comp. B HE sensitivity levels fall in the mid to less sensitive portion of the tables presented. This is best shown by the Susan tests (Figs. 8 & 9). In these tests, Cyclotol and Comp. B are less sensitive than the HMX based PBX HEs. However, they are not as insensitive as PBX 9501 (IHE). The skid drop height of 10 and 4 ft respectively is surprising as compared to the spigot drop test height of 85 ft for Comp B and > 150 ft. for Cyclotol. The skid drop height is used for bare HE handling.

For thermal abnormal environments, several full scale weapon system tests contining Cyclotol as the main charge have been evaluated. These evaluations include both fuel fire tests and accidents. In all of these cases, the Cyclotol did not detonate. The following is a list of these fuel fire test and accidents.

Fuel Fire Tests

1.	W25 (6 tests)	No detonation, HE burned
2.	B28 (1 test)	No detonation, HE burned
3.	W53 (1 test)	No detonation, He burned

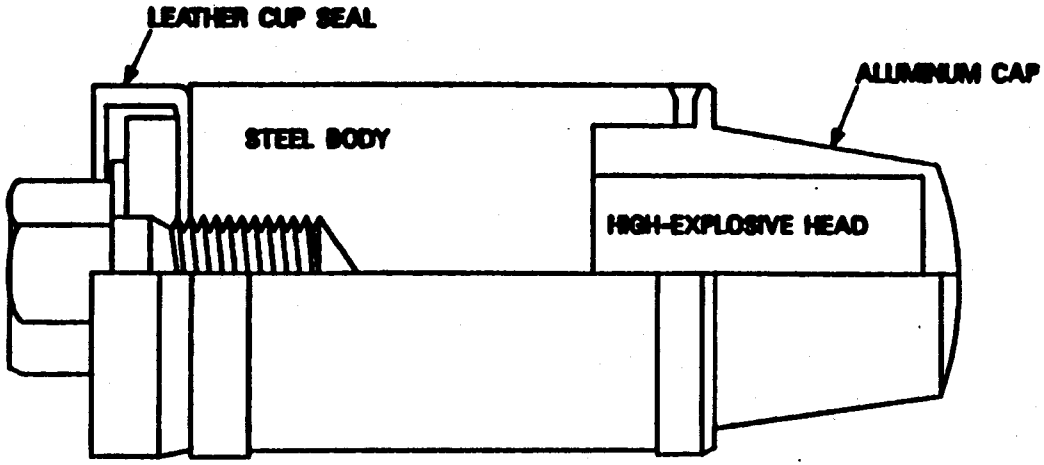
Accidents

1.	Bunkerhill (1964)	No detonation, HE burned
2.	McGuire (1960)	No detonation, HE burned

(D OE b(3))

Four accidents involving impacts have occurred that involved cast HE systems where Cyclotol was the main HE charge. Of these four events, one accident did involve HE detonation. The following lists these accidents.

Accidents Involving Impacts



1.	Cumberland, MD. (1964)	No fire, No detonation
2.	Palomares, Spain (1966)	2 detonated on impact
3.	Thule, Greenland (1968)	No detonation, bombs destroyed by fire
4.	Damascus, Ark. (1980)	No detonation, unit recovered intact

DOE b(3)

HE Degradation

Selected properties of Cyclotol and Comp. B have been evaluated from aged stockpile materials and local testing. These evaluations have indicated that the material still performs as good as new. There are no signs of degradation from aging or incompatibility.

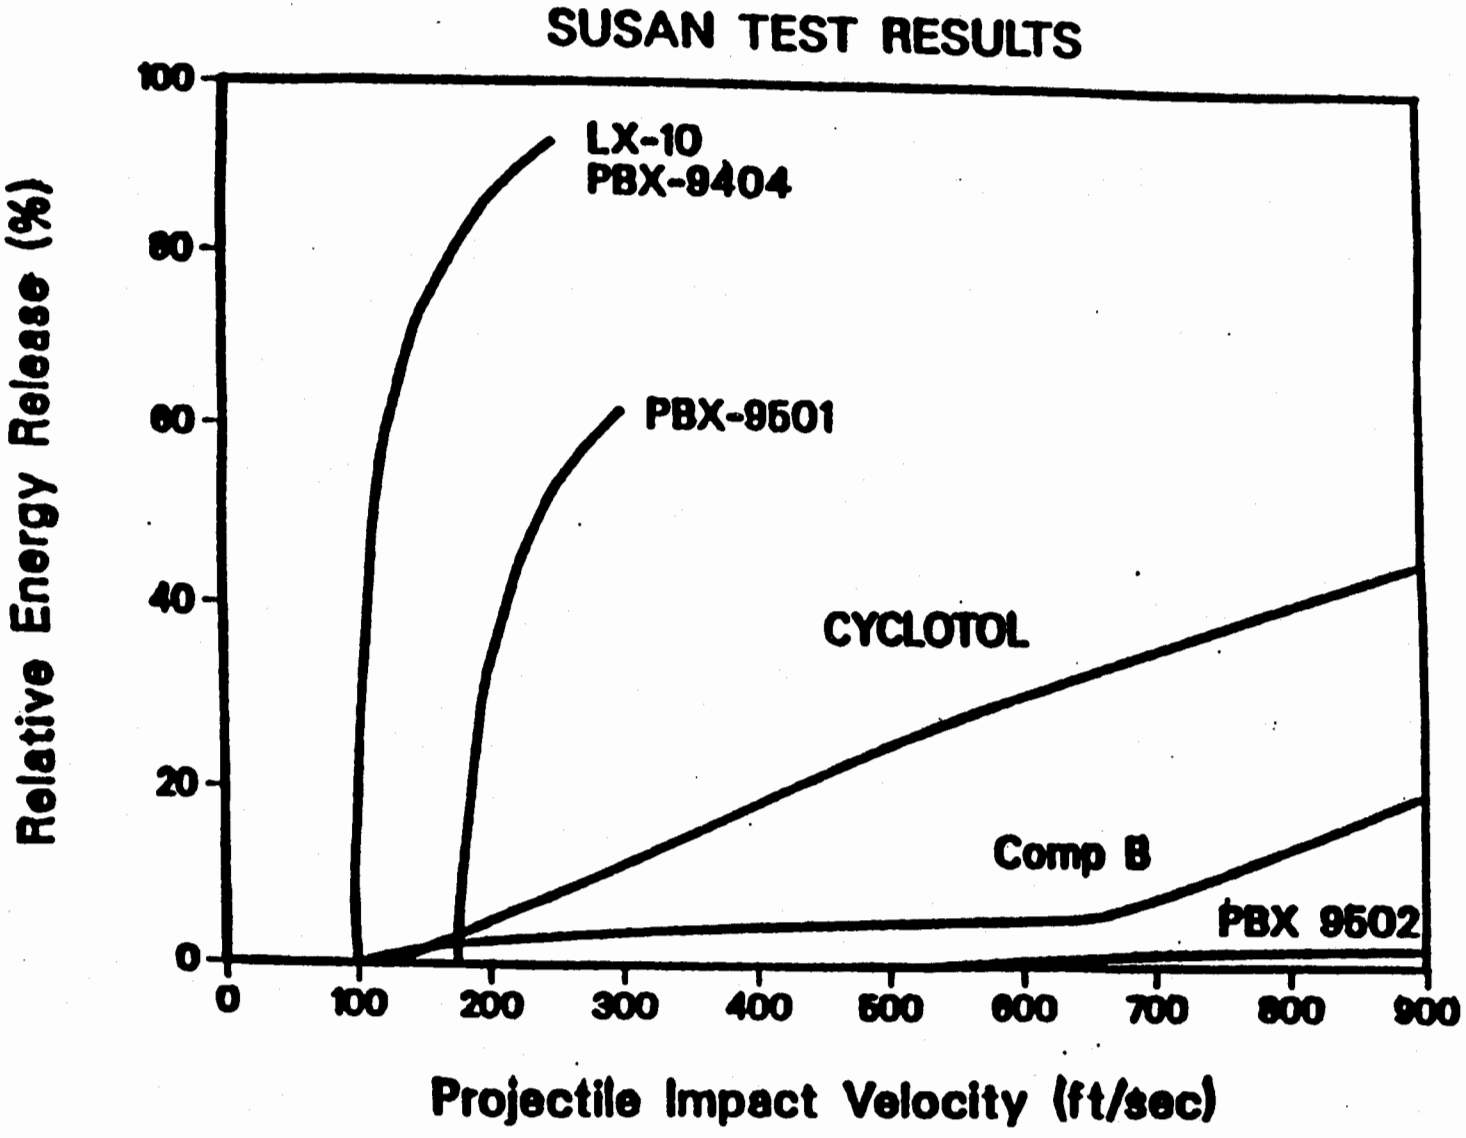

Fig. 9 - Susan Test Results

Material Compatibility

Long term full scale and short term small scale material compatibility tests are carried out for all weapon development programs. These tests involve accelerated aging studies of the warhead materials. In the small scale studies representative material samples are stacked in contact with each other as would occur in the warhead during the stockpile life and are subjected to temperature cycling designed to simulate the STS limits of the weapon and accelerate the aging process. Gas samples are collected and analyzed during the tests, and the small scale assemblies are disassembled and inspected after the test. The tests normally take 6 months, 1 year, or many years to complete, and are intended to represent a 20 year stockpile life. Full scale accelerated aging tests involve the complete weapon and often continue during the stockpile life of the weapon. Incompatibilities that are revealed during the weapon development are corrected by changing materials or design.

Another program carried on at Los Alamos is the explosive compatibility program. Explosives and formulations of explosives and all materials that come in direct contact with them or are employed in HE processing areas are tested. The materials may include floor wax, cleaning solvents, adhesives, mold releases, etc. The tests include vacuum stability tests and differential thermal analysis. Deviations from standard or expected behavior will cause materials to be rejected or forbidden from use with explosives or in explosive processing areas. Current materials found in HE assembly/disassembly areas have been approved for use with ALL explosives in general use today. Therfore, there are no incompatibilities with the materials and surroundings presently found at Pantex and the B53 high explosives.

Stockpile Evaluation

In general, the stockpile and quality evaluation program for the B53 follows that of most other Los Alamos systems. DOE b(3) Typically, bombs are randomly selected from the stockpile and returned to Pantex for disassembly and evaluation. To date, these unit evaluations have revealed nothing of consequence. Minimal HE cracking has been observed but deemed inconsequential. DOE b(3)

Additional stockpile information was obtained when the W53 was retired in 1987-88. These units revealed no problems with the nuclear components other than what is stated above.

The last full SLT was conducted in 1983. Since then, there has been minimal testing of this weapon system. One bomb was looked at in 1987 and another in 1990. A positive outcome from this NESS will allow the evaluation of another B53 bomb.

Detonators

[redacted]

Samples of all DOE detonators are tested during development by thermal cycling, temperature shock, vibration, and acceleration primarily for reliability assessment. These tests also relate to the safety aspects of the detonators. The 1E26 detonator assembly has successfully passed all the environmental tests. Additionally, these detonators have been routinely sample tested during preproduction, production, and stockpile sampling with no deficiencies in safety or operational aspects noted.

Valve Safety

The Type 1A valve is actuated by Type 1A squibs. A piston is driven down through the bore that severs the pit and the bottle tubes allowing boost gas to enter the pit. This valve poses no explosive safety concerns because all the reaction products and the pistion motion are contained within the valve body. The actuators are designed to function under a 28 volt source with a 500 ma all-fire and a 150 ma no-fire current rating.

Actuator ESD Sensitivity

These actuators are known to be sensitive to electrostatic discharge (ESD) when tested with a standard ESD pulse (20kV, 500 pF through 500 ohms) pin-to-case. Tests of the Type 1A squibs have resulted in failure to pass ESD pin-to-case tests with conditions of 5 kV, 500 pF through 500 ohms. Therefore, special bonding practices during all assembly/disassembly operations are required, and shorting plugs should be in place at all times after the firing cables are disconnected.

DOE
b(3)

Fig. 10 - 1E26 Detonator

IV. CRITICALITY SAFETY

Single Units

[redacted] From a criticality perspective, this all-uranium pit has three characteristics which distinguish it from Pu pits found in the stockpile. However, all pits of Los Alamos origin, whether they contain uranium, Pu, or both as the fissile material, only pose a criticality hazard (as single units) during extreme accidents involving water flooding inside the pit.

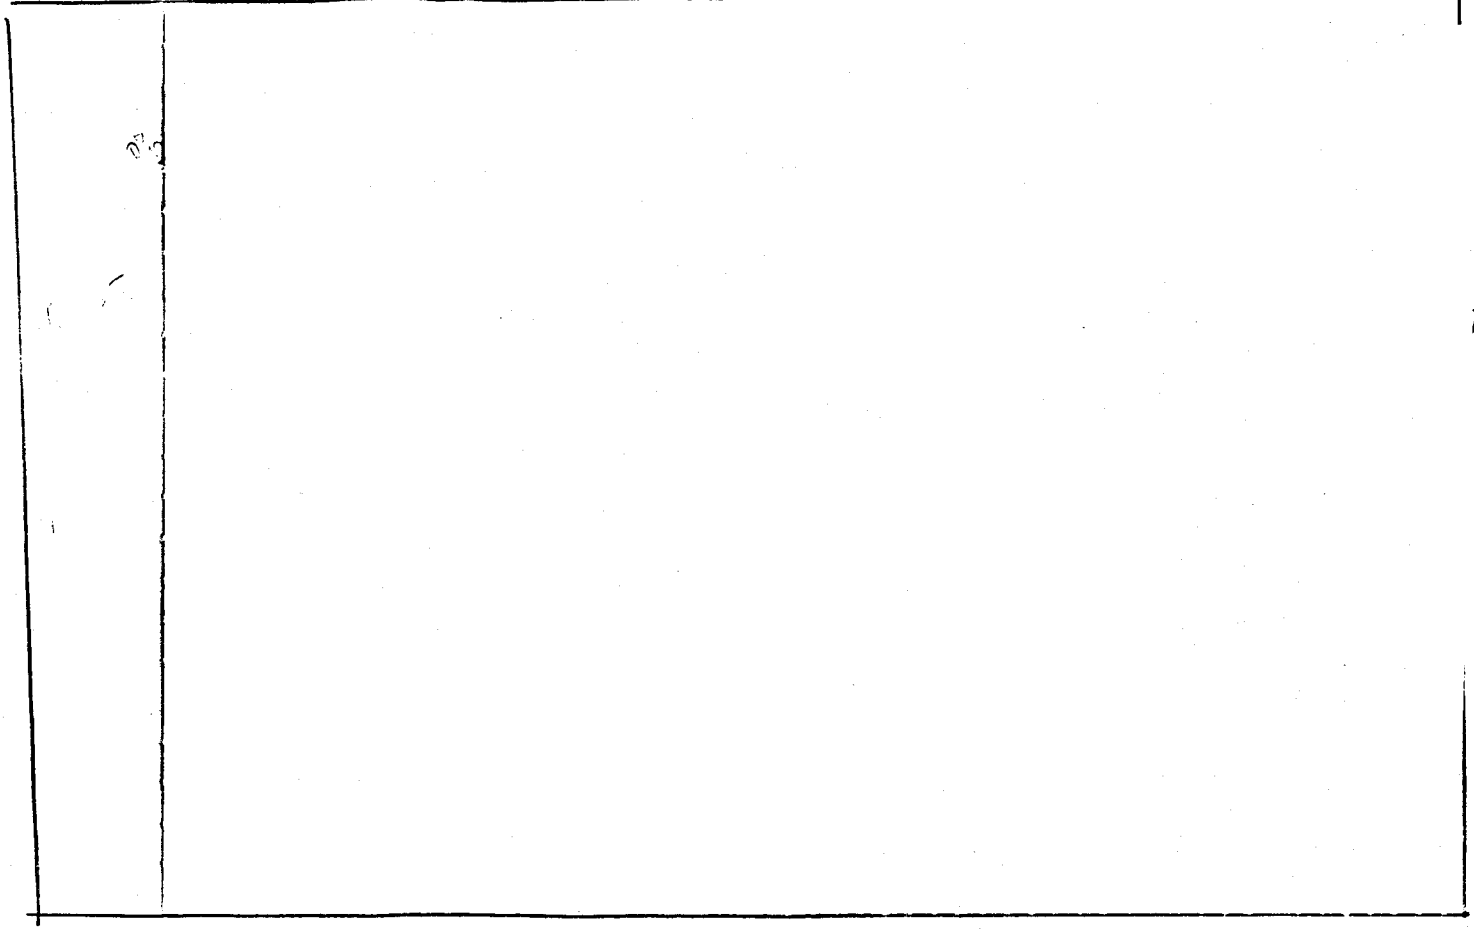
Type 76 Pit

The three distinguishing characteristics are:

* Uranium is corroded much more slowly by water than is Pu, either alpha or delta.
* Uranium is attacked much more slowly by H_2 gas than is Pu, either alpha or delta.
* [redacted]

The implication of these first two points is that prompt recovery (i.e. few days or less) of a B53 from a water environment precludes any credible criticality concerns. That is, insufficient uranium corrosion and hydriding will have occurred to give rise to the hazards discussed (for Pu) in the TP 60-1 manual, particularly section 3-2.5, flooding/criticality. Obviously, if water has not entered the pit then there are no criticality concerns even for prolonged underwater conditions. However, if a unit is involved in an accident leading to even possible internal flooding, then it would seem prudent to assume such.

The two extremes from a criticality standpoint are full water reflection outside [redacted] and essentially zero reflection outside. For these cases, minimum conditions are:



Reflected

[redacted]

Bare

[redacted]

Figure 11 (Figure 11 from Doc. LA-10860-MS) presents critical volume and indirectly, critical mass information which supports these statements

DOE b(3)

Arrays/Multiple Units

DOE b(3)

For a modest number of units (approx. 10), there are no criticality concerns for any spacing/arrangement. This remains true in a water flooded and/or reflected environment.

DOE b(3)

DOE b(3)

The largest, most reactive array achievable is approximately a 2x2x3, based on current stockpile data. For pits in DT-22 containers (the currently approved shipping array), the SAR shows that an infinitely large array would still be subcritical.

Should flooding of a storage area containing multiple units occur and if water ingress to the inside of the pit is considered credible, then the precautions listed under SINGLE UNITS in reference 4 should be observed.[4] 87

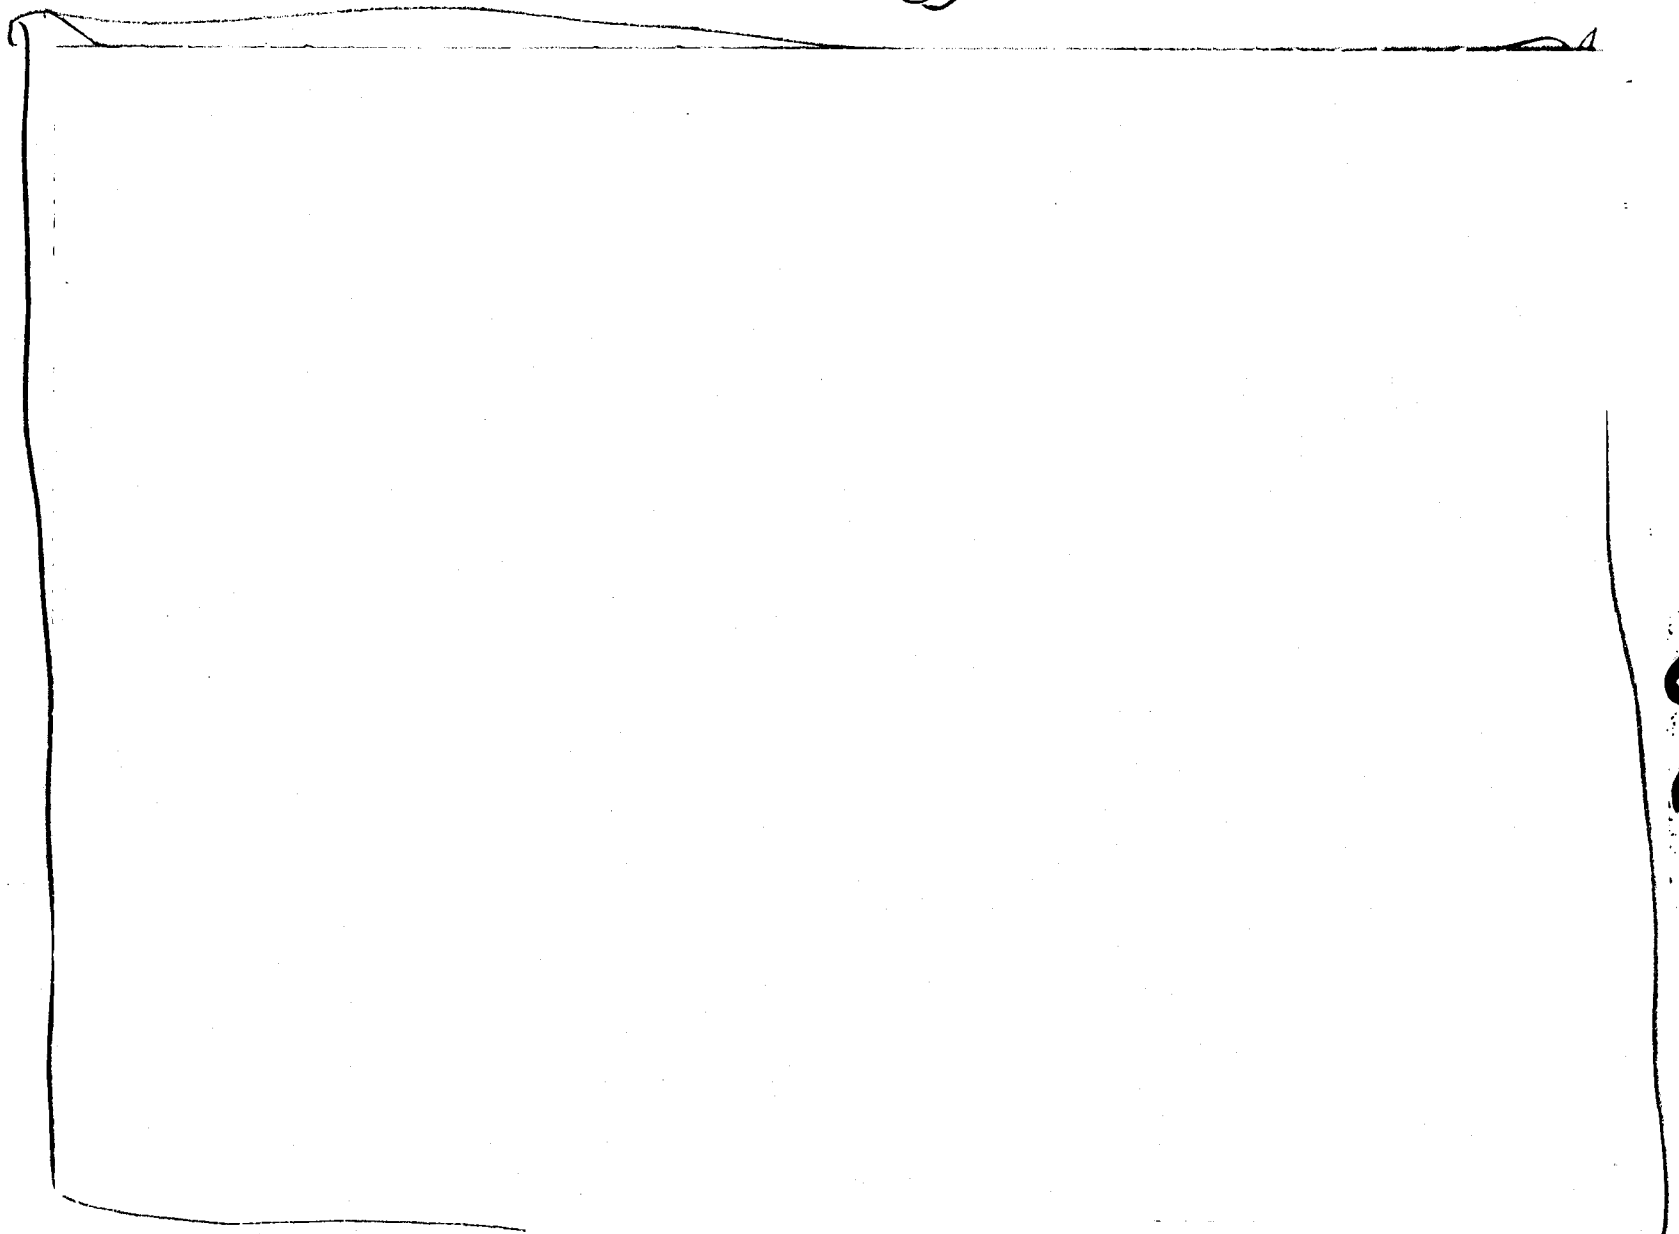


Fig. 19. Critical mass vs ^{235}U enrichment of uranium metal. The dashed line represents the enrichment below which a piece of uranium metal cannot become critical, as determined by an international reactor physics program.

Fig. 12 - Critical Mass vs ^{235}U

V. NUCLEAR EXPLOSIVE SAFETY ORDERS AND SUPPLEMENTAL DIRECTIVE

Los Alamos believes that we are in compliance with the applicable provisions of DOE 5610.11, and AL 5610.11

INTRODUCTION

Following is the Mason & Hanger/Battelle Pantex input document for the Nuclear Explosive Safety 5 year B53-1 Mechanical study. This document presents the Process Flow for Disassembly, Tooling used in handling the Nuclear device, and a listing of all approved O & I Standards.

B53-1 UNIT FLOW

Attachment A defines the typical flow of the unit from receipt at Pantex (by Safe-Secure Trailer SST), through the complete disassembly and inspection process to obtain Parent Unit Parts for support of a B53-1 JTA.

The unit is obtained from the DOD by the DOE and transported to Pantex via SST. At the time of receipt in Zone 4 a receiving inspection for Safeguard Verification (Ref General Standard 7-0849.3), Serial Number and special markings conformation, and potential damage, etc. is performed.

When the unit is scheduled for operations, it is transported to Zone 12-26 loading dock by Pantex transportation personnel. The unit is delivered to 12-104 Bay 8 where it is removed from the H794 Hand Truck.

Disassembly is completed per NEOP N53-301800.

The End Cap Assembly is then staged in Zone 12 and the Basic Assembly is transported back to Zone 4 staging area.

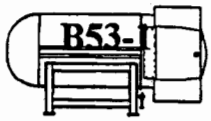
B53-1 NEOP AND O & I STANDARDS

Attachment C lists the B53-1 procedures which will be reviewed during the study. The date and issue may be different due to on-going work at this time.

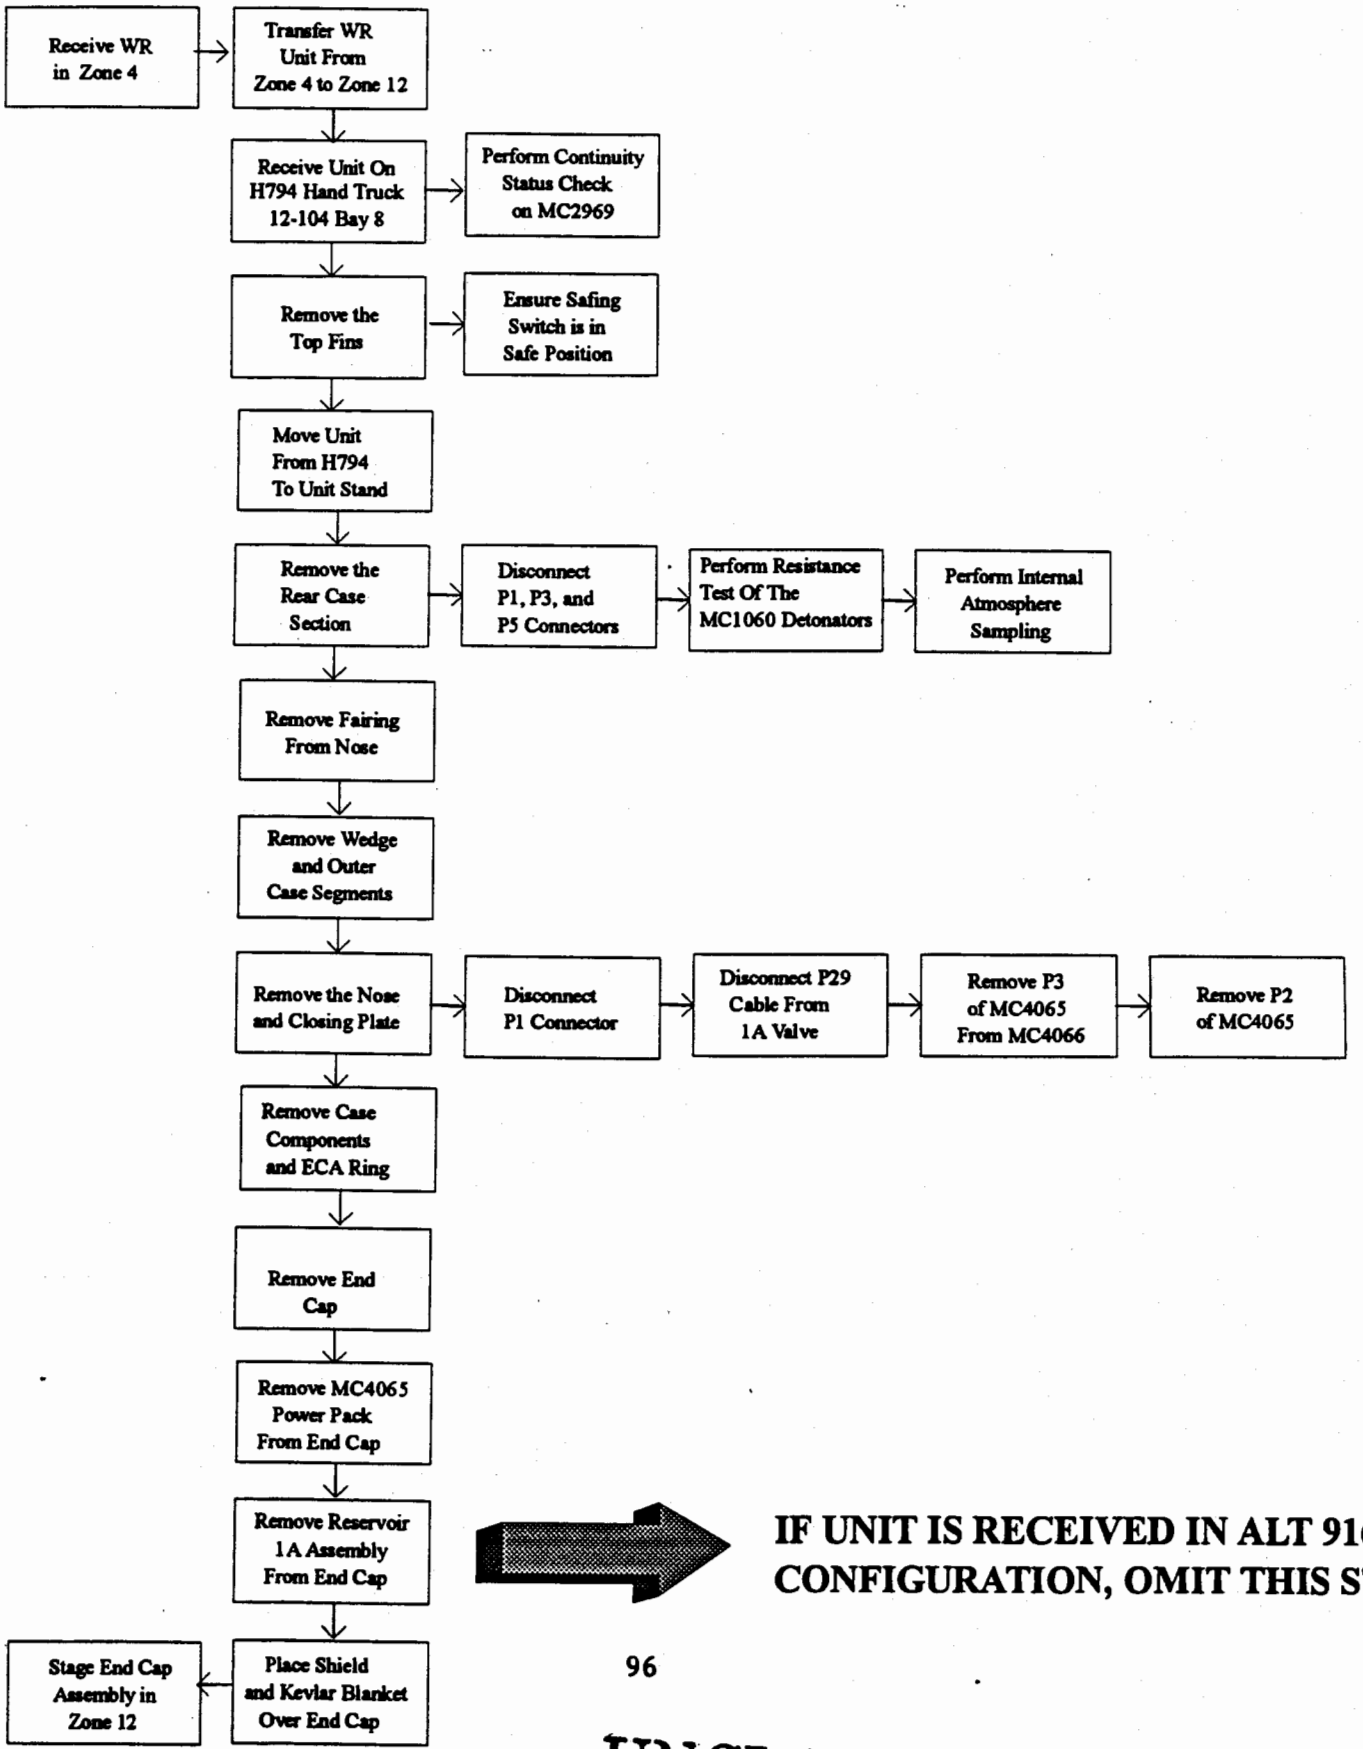
The O & I Standards are all current at this time. The NEOP (N53-301800) will be reviewed prior to the Nuclear Explosive Safety Study according to the current policies which includes, but is not limited to the Evaluation Engineer, Operation Manager, Technical Writer and the Nuclear Explosive Safety Representative. This indicates that the NEOP will have been reviewed by all ES&H Departments, Production Supervision and an Independent Evaluation Engineer.

All disciplines will have reviewed and approved this procedure.

UNCLASSIFIED



NEOP N53-301800 has been through Validation Review with recommendations from the Validation Review Team currently being incorporated.



B53-1 LIFTING/HANDLING FIXTURES

This document also contains a list of the B53 Lifting and Handling Fixtures which are utilized in this Disassembly Process. All load testing of the Special Tooling in question is to be completed as stated in the attachment. All load testing will utilize testing procedures which have been approved by Nuclear Explosive Safety Master Study.

RESTRICTED DATA
Secret

The original design is shown in Figure 2 and the modified design is shown in Figure 3.

DOE b(3)

Figure 2. Original Design

DOE b(3)

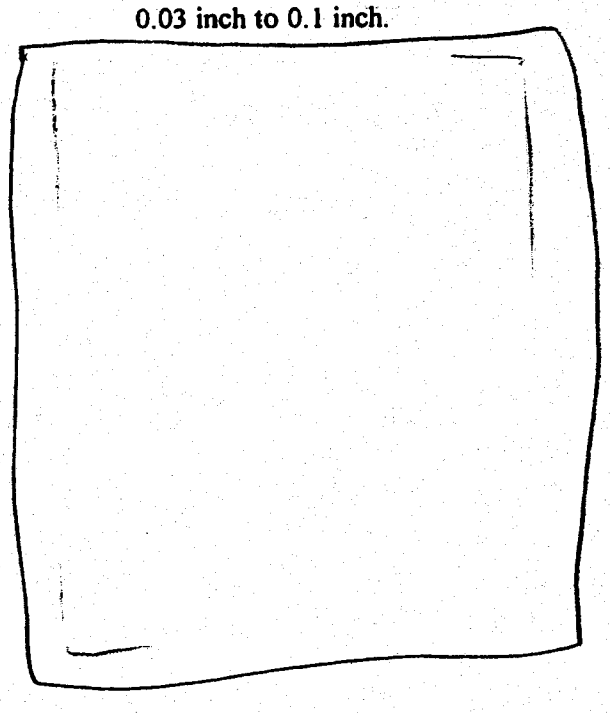

Figure 3. Retrofited Design

There are abnormal environments that will eventually defeat their isolation features. In the B53-1, the strong-link switch is located in relation to existing B53Y1-0 elements that have functions critical to system operation such that these vital elements become irreversibly inoperative before the isolation features of the strong-link switch are bypassed. The weak-links in the B53-1 system are the X-Unit capacitors and the nuclear system high explosive.

The power pack, which contains the strong-link switch is surrounded by the X-Unit capacitor bank. The power pack and the B53-1 system are divided into two zones:

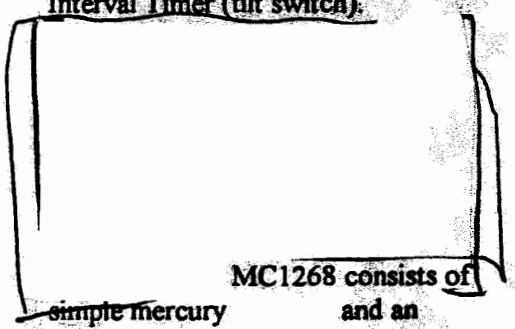
A. Zone 1 contains the input circuits for the MC2969 and most of the B53Y1-0 carryover components.

B. Zone 2 is isolated from Zone 1 and external electrical sources by the MC2969 and the barriers. Zone 2 contains the power converter, the X-Unit capacitors, the trigger circuit, the detonator cables and the primary. The barriers between Zone 1 and Zone 2 are all steel material and varing from 0.03 inch to 0.1 inch.

DOE b(3)

- Lightning protection is provided against inputs to the bomb that could result from lightning strikes by a Lightning Arrestor Connector (LAC) at the bomb/pull-out cable interface. All signals entering the bomb case are routed through the LAC and the shell of the LAC is electrically connected to the bomb outer case. The LAC is designed to

g el fg toT ldg 'calgb ealgd pfr hr



g T o d gn h gArresgArres l ng

explosive except when directed by competent authority."

The B53-1 does not include a PAL, but the design includes the following:

- The Aircraft Monitor and Control (AMAC) system includes a Bomber Coded Switch (BCS), similar to a PAL.

Arming cannot be completed until the Trajectory Sensing System has actuated. Trajectory arming is accomplished by the MC1268 Interval Timer (tilt switch).

MC1268 consists of simple mercury and an electrical therefore, its major contribution ground handling safety.

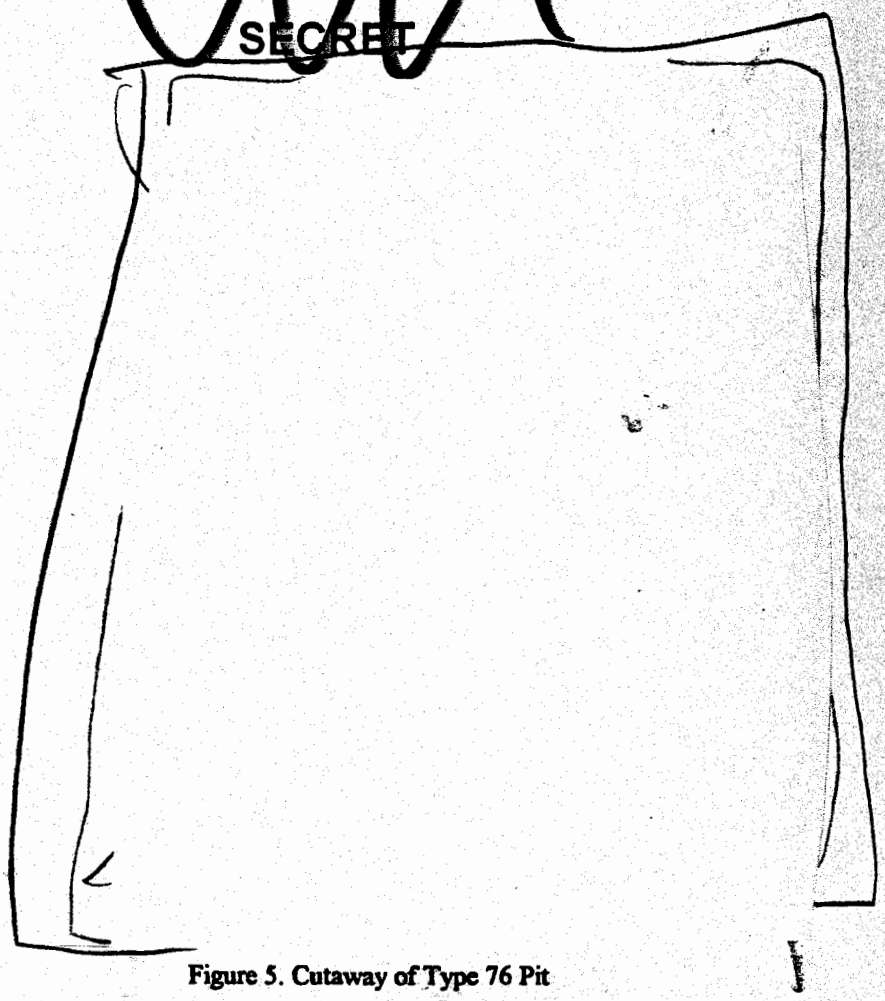
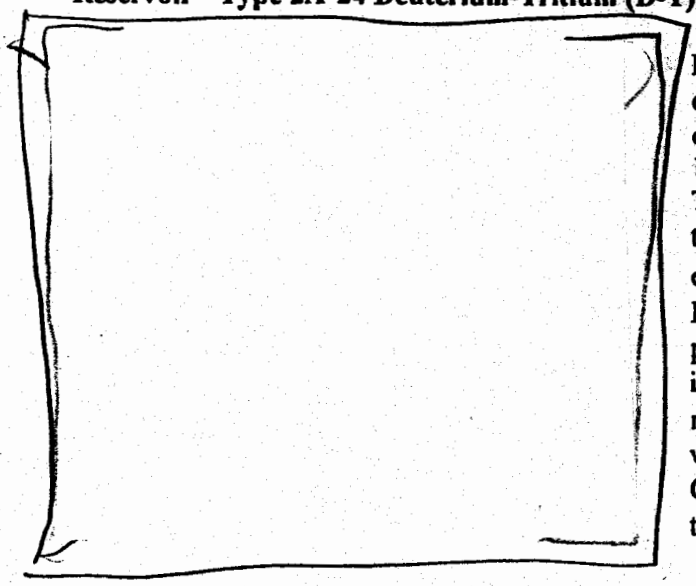
DOE
D(3)





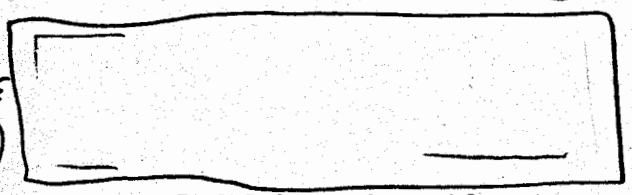


Figure 5. Cutaway of Type 76 Pit

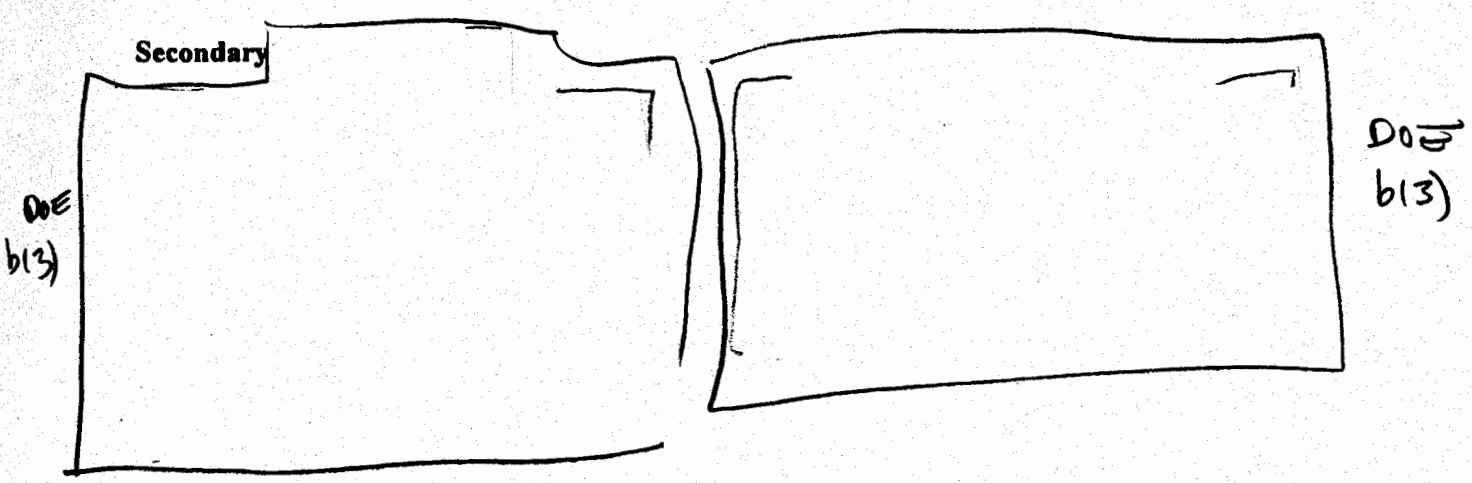
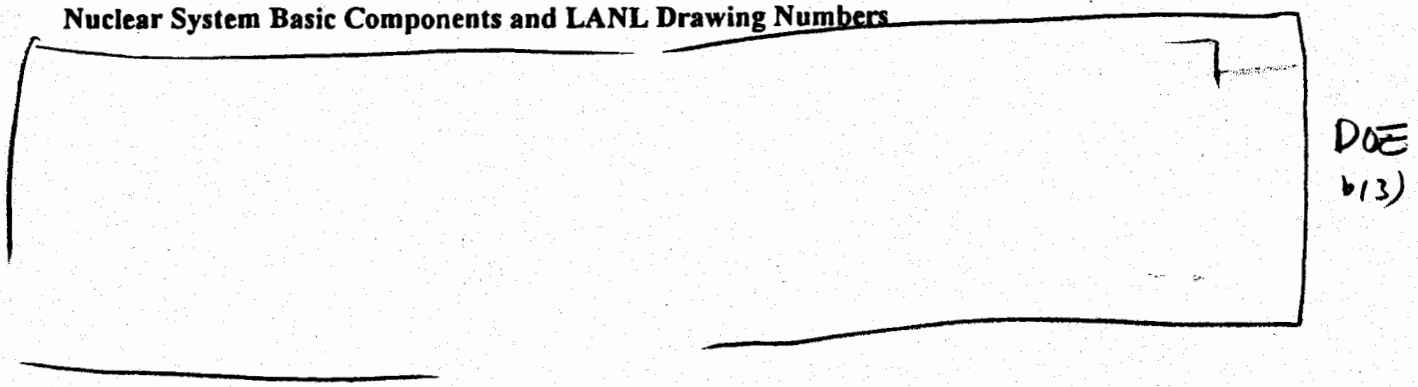
Reservoir - Type 2A-24 Deuterium-Tritium (D-T) gas reservoir and valve assembly

DOE
D(3)

Each Type 1A squib contains an electro-exploding device (EED) that initiates 25 mg of lead styphnate, which in turn initiates 175 mg of Ball Powder (black powder). The Type 1A valve assembly contains a visible thermal plug that is designed to open in a fire environment (operating temperature 104°C). If the actuator squibs fire with the thermal plug open, the gas generated by the actuators is vented to the outside and the plunger will not be forced onto the reservoir and pit tubes with enough velocity to cut the tubes. Cutting these tubes is the only way of transferring the D-T gas to the pit.



Cycle Life - The interval from the fill time to the time that the gas no longer meets the weapon yield certification because of Tritium decay. This life is used to determine the normal LLCE requirements.



Extended Cycle Life - The interval from the fill time to the time that "unacceptable" yield degradation results from Tritium decay and helium generation. This time is greater than the cycle life and less than or equal to the limit life.

Limit Life - The interval from the fill time to the time that the structural integrity of the reservoir, including an appropriate factor of safety, may be compromised, resulting in an increased probability of a Tritium leak.

Stockpile Life - The total number of years that a reservoir can be exposed to a Tritium environment. It may limit the number of times a reservoir can be refilled.

Nuclear System Basic Components and LANL Drawing Numbers

2. Unique signal is provided by the AMAC to enable the MC2929 strong-link switch (requires approximately 25 seconds).

C. Weapon release:

1. Pullout rods are extracted from the MC1200A Fuzing System Control Selector:

   a. Pullout switches in the main thermal battery output lines closed.
   b. Pulse generators in the MC1200A are actuated initiating the MC1262 Thermal Battery Packs (fast-rise batteries) and MC1315 Sequential Timers (parachute timers).

2. MC1262 fast-rise batteries provide 12-volt power:

   a. T_0 contacts in MC1315 timers close.
   b. MC1315s initiate the MC1264 Thermal Batteries (main batteries).

3. 28-volt power is applied to contacts in the MC1268 Interval Timer.

4. [redacted]

   a. MC1315 parachute timer contacts close, completing circuits between the MC1262 fast-rise batteries and the MC1060 Electric Detonators in the automatic parachute deployment system.
   b. MC1315 provides a signal to cut the retardation parachute suspension lines, and the parachute deployment sequence occurs.

      (1) Automatic deployment cover is separated from the rear case section by mild detonating fuze (MDF) system.
      (2) Automatic deployment cover deploys the pilot parachute.
      (3) Pilot parachute deploys the retardation parachute.
      (4) [redacted]

PREFACE

This report is one in a CNSS series that surveys the development of nuclear weapons over the past forty-five years. The unifying themes throughout the series are the technical advances and failures associated with new weapon systems, and the creation of the stockpile.

Authors, titles, and report numbers are listed below.

A BRIEF HISTORY OF THE FIRST EFFORTS OF THE LIVERMORE SMALL-WEAPONS PROGRAM (U)

Lawrence S. Germain

ABSTRACT (U)

This report, one in a series concerned with the history of nuclear-weapon research and development, describes the evolution of the design of fissile nuclear explosives at the Lawrence Livermore National Laboratory from its inception in 1952 to the nuclear testing moratorium in 1958. Nuclear tests are used as the unifying thread for the description of this evolution. The most important families of nuclear devices are identified, their evolution is outlined, and the stockpile weapons that resulted are indicated.

INTRODUCTION

Using the nuclear test program as a framework, this report describes the evolution of the design of fission explosive systems at the Livermore Laboratory up to the 1958 nuclear test moratorium. To understand this evolution one must understand the goals and limitations of the Livermore program. What were they trying to do?

Before 1952, all U.S. nuclear-weapons design was centered at Los Alamos (then the Los Alamos Scientific Laboratory; now the Los Alamos National Laboratory). The establishment of nuclear-weapons design activities at Livermore (then the University of California Radiation Laboratory; now the Lawrence Livermore National Laboratory) in 1952 offered the first opportunity for interlaboratory competition in this area. The Livermore fission-weapons program in those years was based on the assumption that it was not to duplicate active Los Alamos programs.

DOE b(3)

The official status of such a restriction is unclear, but it was the basis of operation at Livermore. At the same

DOE b(3)

SECRET

They all worked—some better than others—but several were of limited or no practical use.

It did serve, however, as a learning experience for the Livermore Small-Weapons Group—mostly green Ph.D.s who were complete novices at weapons design. They developed and used two-dimensional calculations, gained experience with the properties and fabrication of high explosives and fissile materials, and gained experience in nuclear field-test operations.

The story to be told is complex. In Part I, Livermore tests are described in chronological order because this gives the best indication of the development. This sequence can be confusing; thus, to assist the reader, the tests are described in Part II in terms of families that link together in a coherent way.

DoE b(3)

Rainier was detonated on September 19, 1957, in a tunnel in Area 12. Rainier also gave its name to the mesa into which the tunnels were dug (Rainier Mesa) and to the volcanic rocks that cap that mesa (Rainier Mesa Tuff).

DoE b(3)

58A

As more and more weapons entered stockpile and came into the hands of people less knowledgeable about nuclear design, questions about the safety of nuclear weapons assumed more importance. One of the first questions to receive serious attention was one-point safety. The requirement was that no more than four pounds of nuclear yield should be produced as a result of the detonation at *any* one point in the HE, perhaps because four pounds is small compared with the amount of HE in the various devices.

The design physicist was repeatedly scolded for presenting unpromising results. He was urged to make the system work. As a result, he took the most optimistic view of each of the several areas of uncertainty in the design—too optimistic, as it turned out. It was only the nuclear test that revealed the overly optimistic approach. In the absence of nuclear testing, the design errors might never have been uncovered.

If there were no tests to keep the system honest, nuclear designers could be pressured into certifying designs that would not work.

DoE b(3)

As a consequence of these concerns, a series of one-point tests was conducted at the NTS called Operation 58A, which included two safety tests, Venus and Uranus, of Livermore devices. These were carried out between Operation Plumbbob and Operation Hardtack.

DoE b(3)

DoE b(3)

There were other Livermore tests in Operation Plumbbob to which the Livermore Small-Weapons Group did not contribute.

time, the pie split went away. The laboratory directors found it increasingly difficult to reach accord, and the Washington bureaucrats could not countenance such important decisions being made in the field.

[redacted]

This writer was not present at the meeting and has heard two quite different stories about what happened.

DOE b(3)

[redacted]

DOE b(3)

[redacted]

DOE b(3)

[redacted]

Strike 3—and the most important strike. The two laboratories decided to assign the project to Los Alamos. In those early days, there was a rather civilized process known as the pie split. Every year the two laboratory directors and their staffs would meet to decide which tasks would be undertaken by each of the laboratories. The Livermore management always returned from these meetings in exultation, feeling that they had not just taken most of the pie but also the crumbs on the table. However, as time went on the Los Alamos projects remained rock solid while the Livermore projects seemed to fall away, possibly because Los Alamos was taking the mainline projects and Livermore was taking the far out ones. In due

Bradbury said he was not interested. Several of his staff said they were interested. After a caucus, they agreed to the trade.

Story No. 2 is logical. Livermore badly wanted responsibility for a high-yield strategic warhead of their design. Only by having both the primary and secondary of a major strategic warhead identified as "designed in Livermore" could the Livermore Laboratory gain the status of a full partner in the nuclear-weapons design world. In fact, in subsequent years, Livermore made a special effort to gain responsibility for strategic nuclear weapons.

CENTER FOR NATIONAL SECURITY STUDIES

The Center for National Security Studies is a studies and analysis organization of the Los Alamos National Laboratory. Drawing on the broad knowledge at Los Alamos of science and engineering relevant to national security issues, the Center's research focuses on the interaction between technology and policy and on developing insights that may improve the relationship between the development of new technology and the achievement of national policy goals. The Center's staff includes both resident and visiting researchers.

The Center promotes and conducts long-term research and analysis in the broad areas of defense policy and arms control. In addition, it provides insight into near-term national security policy, strategy, and technology issues in support of Laboratory management and staff. The Center also facilitates the exchange of ideas on international security issues among Laboratory personnel, government agency staffs, university faculties, and interested citizens.

The Center documents its work in a number of publications. The ***Briefings*** are informal papers commenting on timely topics that are appropriate to the Center's areas of interest. The ***Reports*** are formal research papers or edited conference proceedings. A book series, ***Issues in International Security***, presents the results of the Center's research on key national and international security issues.

Lawrence S. Germain retired from the Los Alamos National Laboratory in 1985 after thirty years of experience in weapons design and testing in the national laboratories—twenty years at Lawrence Livermore National Laboratory and ten years at Los Alamos. He received a Ph.D. in physics from the University of California, Berkeley, in 1949 and taught physics for four years at Reed College, Portland, Oregon, before joining Livermore. Much of this report is drawn from the author's memory, and many of the opinions expressed reflect his personal recollections.

The first draft of this report was written in 1988, and the information in the report does not reflect events or research since 1988.

A REVIEW OF THE DEVELOPMENT OF LOS ALAMOS GNATS AND TSETSES BEFORE THE 1958 TEST MORATORIUM (U)

Lawrence S. Germain

ABSTRACT (U)

This report, one in a series concerned with the history of nuclear-weapons research and development, outlines the evolution of the Los Alamos Gnat and Tsetse systems before the 1958 test moratorium.

INTRODUCTION

The evolution of nuclear fission explosives at Lawrence Livermore National Laboratory (then the University of California Radiation Laboratory) from its inception in 1952 until the onset of the nuclear test moratorium in 1958 has been treated in Lawrence S. Germain, "A Brief History of the First Efforts of the Livermore Small-Weapons Program (U)," Los Alamos National Laboratory Report LA-11404, May 1990 (SRD).

FALCON and DAVY CROCKETT Warhead Application

1958 Interest develops in lightweight, low-yield warheads for application to FALCON air-to-air missile and DAVY CROCKETT ground-to-ground recoilless rifle.

(b)(1), (b)(3)

1/15/59 Division of Military Application transfers nuclear part of the project to Los Alamos. XW-51 Warhead renamed the XW-54.

10/21/59 Proposed ordnance characteristics of the XW-54 Warhead presented to Special Weapons Development Board and accepted.

12/59 Mk 54 Mod 0 Warhead (FALCON Application) design released.

4/15/60 Mk 54 Mod 1 Warhead design released. This warhead contained no environmental sensing device and was canceled before production.

11/60 Mk 54 Mod 2 (DAVY CROCKETT Application) design released.

4/28/61 Early production of Mk 54 Mod 0 and Mod 2 Warheads.

Special Atomic Demolition Munition (SADM)

2/20/58 Assistant Secretary of Defense notifies United States Atomic Energy Commission that Army has requested feasibility study of an SADM.

(b)(1), (b)(3)

11/10/59 Sandia proposes SADM design to Division of Military Application.

4/7/60 Assistant Secretary of Defense requests Atomic Energy Commission to develop an SADM.

7/26/60 Military characteristics for SADM approved by Military Liaison Committee.

9/5/61 Military characteristics amended to require underwater pressure case.

History of the Mk 54 Weapon

FALCON and DAVY CROCKETT Warhead Application

(b)(1), (b)(3)

The FALCON or GAR-11 was an air-to-air missile being engineered by the Hughes Aircraft Company for the Air Force. The DAVY CROCKETT was a ground-to-ground system designed to fire a projectile from a recoilless rifle and was being developed by the Army.[1]

(b)(1), (b)(3)

It was felt that the warhead would be compatible with the DAVY CROCKETT system and be able to withstand the acceleration produced by the recoilless rifle.

(b)(1), (b)(3)

It was felt that production FALCON warheads might be available by February 1961.

Instrumentation errors were discovered on two flights, and aircraft troubles developed on two others, but the rest of the tests were completely successful.[26]

Report SC4632(WD), Final Development Report for the Mk 54 Warhead Systems, was accepted by the Design Review and Acceptance Group December 14, 1961 and forwarded to the Division of Military Application February 19, 1962. The report noted that the warhead was 10.862 inches in diameter, 15.716 inches long, and weighed about 50.9 pounds. The design included a motor-driven chopper-converter system and contained no power supply.

(b)(1), (b)(3)

The electric system consisted of a firing set and detonator assemblies. This system was a standard chopper-converter design largely using off-the-shelf components. It contained no power source, no one-shot devices, and no components requiring field monitoring, although the environmental sensing devices could be monitored.

(b)(1), (b)(3)

These components were interconnected by printed wiring, and the entire assembly was encapsulated in foamed plastic in a fiberglass housing.

Since the fiberglass housing was electrically nonconductive, it was coated with a conductive lacquer to provide an electrostatic shield from warhead connector to rear cap. This coating was requested by the Department of Defense due to the susceptibility of the fuze to radiated electrical noise generated by the firing set. A connector cover and seal were installed on the

warhead connector after the firing set was assembled to the rear cap of the warhead case.

(b)(3)

Enviromental sensing devices were placed in the input lines to the converter transformer, and these devices remained open during warhead storage and handling, and closed during a launch environment.

In the Mk 54 Mod 0 Warhead for the FALCON application, the warhead was installed in the missile section with its longitudinal axis offset about 1/8 inch to allow room for missile cabling. The FALCON was an air-to-air, semi-active radar homing missile, designed to be launched from F-102A aircraft. The missile diameter was 11.4 inches, length 85 inches, wingspan 24.5 inches, and weight 260 pounds at launch and 200 pounds after motor burnout. The rocket motor produced a total impulse of about 12,900 pound-seconds, which applied an acceleration of 20 to 40 g's to the missile, depending on launch conditions. After rocket-motor burnout, the missile tracked the target on a collision course. The guidance system homed the missile on a target that was

either radar-illuminated by the launch aircraft or by electronic countermeasures emitted by the target.

The missile had a proximity fuze with an operating radius of about 100 feet for a 40-square-foot target. The antenna pattern was in a plane perpendicular to the longitudinal axis of the missile. The output of the proximity fuze was connected to the fuze relay through a safing and arming device.

(b)(3)

The warhead power source in the fuze consisted of two 28-volt thermal batteries. The batteries were initiated about 0.5 second prior to launch and came up to voltage about 1 second after initiation. Battery output was applied to the warhead through the safing and arming device at arm time. This device was a switching mechanism that provided warhead arming by connecting the power supply to the warhead connector and preparing the warhead for firing by connecting the proximity fuze to the fuze relay. This latter device provided switch closure between firing capacitors and pulse transformers of the firing set.

The safing and arming device was latched in the SAFE position until about 1.5 seconds prior to launch. The mechanism had two sets of cam-operated contacts. One set, which was normally open, armed the warhead, and the other set, which was normally closed, disabled the warhead after guided flight in the event of a miss. Both sets were committed during launch acceleration after an environment of about 14 g-seconds.

During the drag phase of deceleration, a spring force developed during acceleration drove the switches to the ARM and DISABLE positions through escapement timers. The escapement time depended on the spring force developed during acceleration and on the deceleration experienced by the missile after motor burnout.

(b)(1), (b)(3)

(b)(1), (b)(3)

The arm contacts were spaced to provide warhead power 0.3 to 0.5 second prior to connecting the fuze relay to the proximity fuze.

(b)(1), (b)(3)

The Mk 54 Mod 2 Warhead was designed for the DAVY CROCKETT, the Army's Battle Group Atomic Delivery System. There were two DAVY CROCKETT systems; the XM28, a lightweight, three-man portable system using a 120mm recoilless rifle with a range of 350 to 2000 meters; and the XM29, a vehicle-transported system using a 155mm recoilless rifle with a range from 350 to 4000 meters. Each system fired an XM388 projectile.

The XM388 projectile included the warhead, rear body and fin assembly, and fiberglass windshield. The projectile had a diameter of 11 inches, length of 30 inches, and weight of 76 pounds.

(b)(3)

A manually operated arm/safe switch interrupted the power supply to the warhead when in the SAFE position. The fuze incorporated a mechanical timer to set the time of flight and to provide safe-separation distance. The fuze contained thermal batteries activated at missile launch to supply power to the warhead and squib switches to close warhead firing circuits.

(b)(1), (b)(3)

At launch, the fuze timer mechanism and the inertial switches in the warhead were actuated. Concurrently, the 28-volt thermal batteries in the fuze were activated, and this action started chopper motors in the firing set. When the preset time was reached, four sets of switches in the timer mechanism closed. Closure of two sets of these switches armed the warhead and initiated the X-unit thermal batteries. Closure of the other two sets of switches connected the X-unit thermal batteries to the fuze. Upon sensing

the selected burst height, a set of squib switches closed and triggered the firing set.[23]

Special Atomic Demolition Munition

The Assistant Secretary of Defense notified the United States Atomic Energy Commission, February 20, 1958, that the Army had recently evaluated atomic demolition devices. There was a requirement for a small and light munition that could be carried by one man. This project, which had been initially called the Tactical Atomic Demolition Munition, would be known as the Special Atomic Demolition Munition (SADM), and a feasibility study was authorized.[27]

(b)(1), (b)(3)

The project was delayed while attention was being given to the design of the XW-54 Warhead for FALCON and DAVY CROCKETT applications, although Sandia informed Albuquerque Operations Office, April 23, 1959, that the XW-54 could be considered for SADM application.[6]

Sandia forwarded a proposal for a nuclear demolition munition to the Division of Military Application November 10, 1959. A modified XW-54 Warhead was proposed, containing an integral fuze compactly packaged in a lightweight sealed waterproof housing, and it was suggested that the entire munition be procured and fabricated by the Atomic Energy Commission. The design would provide a rugged munition small enough for covert missions and capable of being rapidly prepared for firing under conditions of high operational stress where time was critical.[30] It was noted that the only existing munition that approached these requirements was the T-4, an adaptation of the Mk 9 gun-type weapon. However, the T-4 was packaged in four 40-pound sections and required four men for delivery. It was felt that an XW-54 SADM would have a diameter of 11-7/8 inches, length of 17-1/2 inches, and weight of 56 pounds including carrying case.[31]

the dial was protected by a cover sealed with an O-ring. The safed or armed condition of the firing set could be observed through a window in the lock-secured cover.

(b)(1), (b)(3)

The container had a negative buoyancy of about 5 pounds in water and was provided with an external arming device that permitted underwater arming.

(b)(1), (b)(3)

(b)(1), (b)(3)

With the control in the ARM position, the time-delay setting could not be changed. When the arm/safe control was returned to the SAFE position, all safety features and interlocks were reengaged.

(b)(1), (b)(3)

Upon completion of manual arming and after the preset time-delay interval, the timer provided firing signals which activated the electric detonator. This detonator created a shock wave that actuated the explosive plane-wave

generator and created a high-energy planar shock wave that impinged on the transducer. This resulted in a rapid stressing of the ceramic transducer and produced a high-peak-energy pulse that initiated the high-explosive/nuclear system detonators. The resultant implosion of the high explosive initiated the nuclear reaction.[54]

A Mk 54 Mod 2 SADM, with the same diameter and length attained early production in June 1965.

(b)(1), (b)(3)

The weight was increased to 70 pounds.[55]

History of the Mk 55 Warhead

By the fall of 1956, design was in progress on the Mk 44 depth-bomb warhead, designed for surface-ship attack of enemy submarines. Subsequently, the possibility of developing a warhead that could be launched from one submarine against another was raised and, September 19, 1956, the Assistant Secretary of Defense requested the United States Atomic Energy Commission to cooperate with the Navy in a feasibility study of a nuclear warhead for such a submarine-launched torpedo.[1]

This study was conducted during 1957. The missile was called SUBROC, and was a rocket-propelled missile launched into the atmosphere from a submerged attacking submarine and designed to attack a target submarine located underwater at some distance.

(b)(1), (b)(3)

In response to a teletype from the Division of Military Application, Sandia noted, December 26, 1957, that warheads could be supplied by March 1960. However, complete design release could not be made until flight tests had provided adequate proof of warhead and missile system compatibility. These flight tests would start in the fall of 1959 and continue into 1960. It was felt that the design might be released by December 1959, and that production warheads would be available by October 1960.

Warheads for the first two submarines would be produced in accordance with design information available in August 1959. These units would not be of full production quality since flight test data would not be available, although much of the critical laboratory testing would have been completed.

(b)(1), (b)(3)

RESTRICTED DATA SECRET

UNCLASSIFIED

The Special Weapons Development Board met January 22, 1958 and listened to a presentation on the proposed SUBROC weapon. It was pointed out that the United States was committed to the economic and military support of the 15 member nations of the North Atlantic Treaty Organization (NATO), located on four continents. Since this support required maintenance of seaborne and logistic links, the collective security of NATO could be seriously jeopardized by an aggressive enemy submarine campaign. There was thus an urgent need for an effective anti-submarine warfare (ASW) weapon system.

Submarines appeared to be the most suitable delivery vehicles for such weapons, but available submarine-launched weapons had only limited effectiveness. Torpedos were reasonably efficient only to a range of about 10,000 yards (less than 6 miles). High-speed torpedos were noisy and alerted their targets. Long-range, quiet torpedos required command inputs during travel to target, and were relatively slow. It was felt that a SUBROC-type missile would greatly enhance the ASW capabilities of the Navy's submarines.[4]

Meanwhile, the Bureau of Ordnance, in a letter dated January 17, 1958, noted that the SUBROC study had been completed and requested the cooperation of the United States Atomic Energy Commission in a feasibility study of a suitable warhead.

(b)(1), (b)(3)

(b)(1), (b)(3) The outside diameter would be 13 inches, length 42-1/8 inches, and weight 370 pounds. Reasonable variations in these parameters would be acceptable in order to develop an optimum missile/warhead combination.

(b)(3)

The Division of Military Application, in forwarding the military characteristics, referred to the moratorium on nuclear testing. If dimensional limitations could not be satisfied without further testing, the Military Liaison Committee would be informed concerning those parameters that could be provided without such testing.[9]

Development was authorized for the SUBROC warhead application March 24, 1959, and Sandia notified Albuquerque Operations Office April 17, 1959 that the designator XW-55 had been assigned to the program.[10] Plans were made for air-gun and drop-tests to certify the structural adequacy of the warhead for water entry. A relatively small number of flight tests would be required, and full-scale firings would be made in early 1960.[11]

Sandia forwarded the development program definition on the XW-55 Warhead to Albuquerque Operations Office August 31, 1959. The warhead would fulfill requirements for a 450-pound warhead for the SUBROC missile. The military characteristics had specified a warhead weight of 370 pounds, but it was found that missile stability required that additional weight be placed as far forward in the missile as possible, and the Bureau of Ordnance requested that a suitable change be made to the military characteristics.

(b)(1), (b)(3)

(b)(1), (b)(3)

The design would be released in mid-1962, and early production was scheduled for the second quarter of calendar 1963. The warhead would be operational by July 1963.

The warhead would have a maximum diameter of 13 inches and maximum length of 39.4 inches.

(b)(1), (b)(3)

The firing system would include a chopper-converter, capacitor-type X-unit, and acceleration-sensing handling safety devices. The warhead would be sealed and would require only continuity monitoring in stockpile or field.

The SUBROC was designed to be fired from a Navy standard 21-inch-diameter torpedo tube. The missile would have a maximum diameter of 21 inches, length of 246 inches, gross weight of 4000 pounds, re-entry depth-bomb weight of 900 pounds, and a range from 5 to 35 nautical miles. Velocity at water impact at the maximum range would be about 1500 feet per second and the missile would have a solid-fuel propulsion system.

Due to high-load-factor requirements, the case would be built of high-strength steel having a yield point of about 160,000 pounds per square inch.

(b)(1), (b)(3)

The military characteristics were amended by the Military Liaison Committee November 12, 1959. The weight of the warhead without frangible nose section was increased to 450 pounds, including ballast if necessary. The warhead would be compatible with such other applications (in addition to the SUBROC) as might be authorized by the Department of Defense.[13]

By April 1960 it had been decided that a g-second environmental sensing device would provide maximum warhead safety. Although the weapon was being designed specifically as an underwater-launched air-trajectory missile for depth-charge application, it was felt that the warhead should also have a capability for air-burst detonation, or operation independent of the water-entry environment. Thus, an environmental sensing device actuated by launch environment was desired. Devices currently available did not meet SUBROC requirements, with its relatively low launch acceleration.[14]

Sandia published Report SC4818(WD), XW-55 Warhead, Proposed Ordnance Characteristics, in October 1961.

(b)(1), (b)(3)

The report had been previously reviewed by the Design Review and Acceptance Group and found to be satisfactory with the exception of monitoring provisions.

(b)(3)

The report noted that design release was slated to start in January 1962 and to be completed during June 1962.

(b)(1), (b)(3)

The trajectory would be

guided during both boosted and unboosted phases.

(b)(1), (b)(3) Upon re-entering the water, the missile would sink to a preset depth and detonate.

The missile weighed about 4200 pounds, including a 3300-pound motor section. The depth-bomb section contained a warhead, adaption kit, auxiliary power unit, and guidance and control system. The control system used fins to guide the missile after the depth bomb separated from the rocket motor. To provide enough fin area, the diameter of the depth bomb was restricted to 13 inches. The depth-bomb section weighed about 900 pounds. An aerodynamic nose fairing, attached to the front of the ballistic case, would be wiped off at water entry, exposing a flat nose which provided underwater stability.

(b)(3)

Shock tests simulating water entry at 1420 feet per second were reported November 13, 1961. Results demonstrated that the weapon case could withstand this shock without damage.[16]

Field Command notified Sandia, November 22, 1961, that the proposed ordnance characteristics had been reviewed with representatives of the interested Services.

(b)(1), (b)(3)

However, this deviation was temporarily accepted, pending results of further tests. There was also a requirement for physical separation of a vital component from the warhead. Inasmuch as the design included multiple safety devices, the Navy felt that the intent of the requirement had been met. It was noted that

radiation from the warhead should not be more than 0.1 Rem per week, but this figure had been exceeded, and the Navy was requested to restudy the requirement. The design was meanwhile considered acceptable to the Department of Defense.[17]

(b)(1), (b)(3)

The Lawrence Radiation Laboratory notified the Division of Military Application June 9, 1962 that the XW-55 Warhead, while in storage, emitted gamma-ray and neutron radiation in an amount somewhat greater than allowed by the military characteristics. The Naval Ordnance Laboratory suggested that shielding, as well as a security cover, be placed on each warhead. This added structure would weigh about 400 pounds, and it would be necessary to repeat an extensive series of vibration and shock tests, and possibly redesign the warhead.

Since the radiation level decreased rapidly with distance from the warheads, it was felt that only the warheads adjacent to the passageway would contribute significantly to radiation in the passageway, and it was recommended that the passageway be provided with appropriate shields, or that no warheads be stored next to the passageway.[19]

The warhead was tested on a hydraulic centrifuge in the launch orientation to a linear acceleration of 10 g's, and no structural damage was noted.[20] A shock test was reported September 21, 1962, which simulated the environment of a depth-charge attack made on a submarine carrying the XW-55 Warhead. Again, no damage was noted.[21] Other successful tests included roll acceleration, shipping vibration, dynamic heating, thermal cycling and shock, vibration of warhead and missile, electrical system, simulated water entry, hydrostatic, bottom impact and depth-charge shock, and cookoff tests.[22]

By July 1962 it was learned that the operational availability date of the SUBROC missile had been postponed from November 1963 to April 1964.[23] Accordingly, early production of the XW-55 Warhead was deferred to January 1964.

The Mk 55 Warhead was design released March 20, 1963.

(b)(1), (b)(3)

Field Command notified Sandia April 30, 1963 that Report SC4854(WD), Mk 55 Mod 0 Interim Development Report, had been reviewed in coordination with representatives of the Services.

(b)(1), (b)(3)

It was considered that the design was acceptable to the Department of Defense.[25]

The Mk 55 Mod 0 Directive Schedule was published July 31, 1963, and authorized quantity production and stockpiling. Early production of the warhead was achieved in January 1964.[26] In accordance with a request from the Department of Defense, the warhead weight was ballasted to 465 pounds rather than 450 pounds. The overall length of the warhead without frangible nose section was 39.283 inches, instead of the specified 39 inches.

Report SCL-WD-64-28, Mk 55 Mod 0 Final Development Report, was presented to and accepted by the Design Review and Acceptance Group July 23, 1964.

(b)(1), (b)(3)

Timetable of Mk 56 Events

4/4/58	Assistant Secretary of Defense requests United States Atomic Energy Commission to cooperate in feasibility study of 330- and 550-pound warheads for the MINUTEMAN missile.
5/5/58	Feasibility study group recommends development of two warheads.
12/58	Division of Military Application reconvenes feasibility study group to consider a 600-pound warhead.
3/2/59	Feasibility study group reports that a suitable 600-pound warhead can be provided.

(b)(1), (b)(3)

9/15/59	Military Liaison Committee releases set of military characteristics for the MINUTEMAN warhead.

(b)(1), (b)(3)

11/20/59	Division of Military Application assigns development nomenclature of XW-56 and XW-56-X1 to the above designs.
12/24/59	Sandia issues development program definition of the XW-56 Warhead.

(b)(1), (b)(3)

8/60	Sandia publishes proposed ordnance characteristics of XW-56 Warhead.
10/13/60	Director of Defense Research and Engineering selects 600-pound XW-56-X1 design for MINUTEMAN.
12/1/60	Division of Military Application cancels XW-56 Warhead program. XW-56-X1 to continue and be called, in production, the Mk 56 Mod 1 Warhead.

3/24/61	Lawrence Radiation Laboratory and Sandia-Livermore forward development program definition of XW-56-X1 to Albuquerque Operations Office.
9/61	Production of XW-56-X1 Warhead authorized.

(b)(1), (b)(3)

12/18/62	XW-56-X2 Warhead interim development report accepted by Design Review and Acceptance Group.
3/63	Mk 56 Mod 1 Warhead final development report released. Early production attained.

(b)(1), (b)(3)

10/63	XW-56-X3 Warhead preliminary development report issued. Redesign provides hardening against weapon blast effects. (Product Mod 3)
8/64	Early production of Mk 56 Mod 2.
9/64	Mk 56 Mod 1 supplement to final development report notes that the warhead safing system has been improved.
4/65	Mk 56 Mod 2 Warhead final development report released. Warhead hardened against blast effects.
3/66	Mk 56 Mod 2 supplement to final development report notes that the stockpile life of the neutron generator meets requirements of the military characteristics.
5/5/66	Division of Military Application requests hardening of warhead against effects of high-energy X-rays.
12/66	Design release of Mk 56 Mod 3 Warheads.

2/67	Early production of Mk 56 Mod 3 Warheads.
3/21/67	Sandia proposes additional hardening of warhead against X-rays.
5/24/67	Design release of Mk 56 Mod 4 Warheads.
5/67	Early production of Mk 56 Mod 4 Warheads.

History of the Mk 56 Warhead
